The squares are for hives, with a star to indicate entrances. Hives are to face east and west alternately, in rows; alleys between entrances, 6 feet; alleys between hives, at backs, 10 feet, which is the work alley, the one to run the wheelbarrow in, and to travel back and forth in. You will observe that, while you are in this alley, you are 10 to 15 feet away from the face of any hive, and therefore the bees in their outward flight are far above your head, where they will not annoy you nor you them. If you wish to see the difference this makes, you have but to step over into the other alley, and stand a few minutes, to be convinced.

As to mixing of bees, and queens mistaking hives, although your hives may be as much alike as two peas you will see, by referring to the hives marked A and B, that a bee or queen, to find a hive in just the same position as her own, has to go across two alleys, and 20 feet away—a mistake she is not likely to make, the location alone determining her home. In fact, there has been less trouble from bees and queens mistaking hives with this than the old hap-hazard arrangement. I think a fair trial will convince any one of its merits.

C. A. HATCH.

Ithaca, Wis., Mar. 11.

Your article, friend Hatch, is timely and to the point. I have been studying on this

matter of arranging hives in the apiary, for some time. I have never liked the hexagonal arrangement in our home yard, with grapevines. I thought they were too close; and so when we got down to the basswood apiary we put the hives 12 feet apart, all facing one way, each hive in the shade of a basswood-tree. Much to my surprise I found it took a good deal of time in running from one hive to another. I then came to the conclusion that we wanted them closer together. Accordingly, this spring when we set our bees out of the cellar I arranged the hives in groups of four—hives 12 inches apart, and the groups 6 feet apart. The first group was made like A, the next like B, and so on, each one differing from the other. On the next row we start with C just opposite A. By this arrangement you will see that the entrances were facing in all directions, so the bees could not mistake where they lived. I thought it was very unique, and so I was quite sanguine I should like it. But after I had worked among the bees as so arranged, I became very much disgusted. I could not sit down to work at a hive anywhere without encountering the flight of bees, especially when I took a positoin at A, at groups B and C. The bees, seeing some great object

in the midst of their groups, would stop, hesitate, buzz around, and fill the air. This is, to a certain extent, true when working over one hive; but it is four times as bad when the entrances of the four hives are close together. Group A does very well. But if all were like this it would offer no dissimilar arrangement for the bees. I have been trying to think of some better arrangement, and your plan strikes me as the best of any thing I have yet seen. When our out-apiary is set out for this season I propose arranging it on just that plan exactly. The fact that it is similar to Dr. Miller's arrangement, and the fact that you are one of the most extensive bee-keepers of your State, and that you like it, is much in its favor. The plan of avoiding the flight of bees, in going about with wheelbarrows and such like, is capital. There is one thing which you have omitted to mention; and that is, the facility with which a lawn-mower can be run among hives that are parallel and square, instead of hap-hazard, or on the hexagonal plan. In our hexagonal apiary it is very inconvenient to run a lawn-mower around among the hives, because one hive comes directly in the passageway of the next row. We were obliged to run it zigzag; and we found, several times, that we had thereby given a hive an unlucky "tunk," as you so happily express it. With your arrangement a lawn-mower could be run straight along, clear through the rows, without any zigzag about it. On

three sides you would not encounter any entrance. At night the entrance sides should be mown down, when the bees are not flying. Perhaps a good many apiarists do not think it necessary to keep the grass down with a lawn-mower. Of all things I do hate, it is to wade through wet grass, when the dew has been heavy the night previous, in making visitations to the hives. It is only a couple of hours' work a week to run a lawn-mower through a whole apiary of, say, 75 or 100 colonies; and, aside from the neat and orderly appearance, it pays in other ways, for it keeps the bottoms of the trowsers dry, and makes it necessary to wear only rubbers. We should be glad to get suggestions from our correspondents. E. R.

In addition to the above, permit me to say that, in most of the California apiaries, they have come to the same conclusion with friend Hatch; that is, having narrow alleys set apart for a pathway or thoroughfare for the bees. The operator is not supposed to go into these narrow alleys at all. As nearly as I can remember, 6 feet was perhaps the width of these; then a broader alley, say 10 or 12 feet, was left for the operator. Of course, he can cross from one broad alley to another, if he chooses; but his general work is to be done in the broad alley; and in opening hives and working with them, the narrow alleys are not to be occupied. The bees seem to recognize this narrow alley as their own allotted highway; and when they are working heavily the narrow alleys are literally full of buzzing bees, while the broad ones are comparatively free. These double rows of hives with a double alley between them, may center, like the spokes of a wheel, toward the door of the honey-house. I would suggest to friend Hatch that his hives may be in straight rows, and still be on the hexagonal plan; and this plan gives each hive a greater amount of space than we can get in any other way.

CRATING AND MARKETING HONEY.

Continued from last issue.

I HARDLY know whether this fact should be more emphasized or not; at all events, hardly any one likes candied comb honey whether they understand its nature or not, and people who don't understand this crystallizing property of honey say instantly, "Oh! that is manufactured honey, isn't it?" or another says, "That is some sugar you have put in." These friends compare the retail price of honey, 18 and 20 cts., with the price of sugar, 7 and 8 cts., and think there is an immense profit to us in turning sugar thus into honey. Of course, they don't know, nor can we very well explain, that the wholesale price of honey in barrels is about the same as good sugar, thus making it out of the question to adulterate honey profitably. Glucose makes an unpalatable mixture, and can't be counted.

Right here, while speaking of the price of honey, I wish to call some of our dear brethren to account for selling honey so cheaply. One brother sold $\frac{3}{4}$ -lb. glass tumblers for \$1.00 per dozen in Toledo. The tumblers cost, any way, 30 cts. per dozen, whole sale, leaving a little less than 8 cts. per lb. for

the honey, put up in small receptacles. Another of our bee-keeping friends has been putting up pint Masons (holding $1\frac{1}{2}$ lbs.) for 20 cts. each, by the dozen. If he gets his jars for 6 cts. each by the gross he is lucky, leaving 14 cts. for $1\frac{1}{2}$ -lbs. of honey, and labor of filling, etc. Now, we have disposed of nearly 30,000 lbs. of honey in the past two years, and the bulk of it has been sold at 18 to 20 cts. per lb., and we charge extra for the glass jars. We have sold honey thus in Cleveland, Canton, Akron, Massillon, Newark, Zanesville, Columbus, Findlay, Tiffin, and several other Ohio towns, and in Logansport, Lafayette, Ft. Wayne, and Indianapolis, in Hoosierdom. The above is our uniform experience.

It is next to impossible to find a lot of comb honey that has no pollen in some of the cells. In some way I can not explain, this is an attraction for the moth, and many a disgusting task I have had of cleaning them out of a lot of nice comb honey. To avoid this, sulphur them, of course; but just when to do this with most profit to all concerned, I know not. Perhaps some brother who has had experience in this particular line will kindly inform us.

One thing in regard to the general appearance and quality of honey. Let our bee-keeping friends remember that grocers as a rule will have nice, neat-looking white honey or have none at all. What kind of appearance do you suppose honey presents with all the bee-glue on it, as when removed from the hive? In several instances I have seen comb honey that had been shipped to market in the very cases that held it on the hive, with all the unsightly bee-glue adhering. Why, such a thing is as much behind the advanced spirit of the times as the stage coach or the wooden plow. Let us all remember that beauty and neatness are prime requisites for success in any line of goods we present to the public. People living in our cities have the importance of this matter impressed on them at every hand, and here competition is swift in inventing new and artistic effects. Our farmer friends must bear in mind that this is the class of people who approve or condemn their methods, and use no charity in so doing, but adopt the rigid rule of comparison.

Once for all, let me say, send no dark honey to our city markets. Practically, no one wants it; and you can make more money out of it by feeding in spring to your bees or marketing to private families through the country.

The only way to fight these infamous lies, in circulation about the bee-business, is for each one of us to write articles for our home, county, and local papers, where our word is taken as authority. The persistence and scope of these misstatements, no one can fully realize who has never sold honey in the cities and away from home. There would be 100,000 lbs. more honey eaten per year if all who like honey had confidence in what is offered them.

An eminent financier has said, "Confidence is the life of trade," and this is eminently so in the bee and honey business. My brother said once, "If any one ever ate any good honey, and had the slightest suspicion that we sold it, he will buy more, without question."

H. F. MOORE.

Cleveland, O., Apr. 4.

Friend M., you do not mention our reward cards for these people, but I suppose you have them. I am glad of your caution in regard to unfinished sections of the pre-

vious year. This has been quite thoroughly discussed in our conventions, but a great many don't seem to get hold of the whole of it. I am sure the old honey, section and all, had better be thrown away, unless every particle can be cleaned out of the cells by the bees, so as to leave nothing that can start the new honey to candying. Throwing honey out by means of the extractor will not answer. It must be given to the bees to clean off afterward. Our experience with dark honey has been just about what you say. Nobody wants it at all.

A HOME-MADE EXTRACTOR.

ITS MERITS AND DEMERITS.

I INCLOSE with this a photograph of my extractor. It is composed of eight pieces, all of which, or a

substitute for most of them, are generally obtainable by what I call an amateur bee-keeper; for instance, a hickory sapling, a few boards nailed together, and the corners cut off, take the place of the wheel; and with $\frac{1}{2}$ -inch lumber a box might be made to take the place of the can, or the can might be made from two old five-gallon square honey-cans. For my device I took a long

stout pole. The wheel I used was the front wheel of a light wagon. I cut the pole down to 7 feet, the height adapted to my cellar. In the bottom of the pole I drove an iron plug $\frac{1}{4}$ inch in diameter, allowing it to extend about $1\frac{1}{4}$ inches outside. I then bored a $1\frac{1}{4}$ -inch hole through a piece of hard wood, long enough to be nailed on two joists overhead. I then bored a $\frac{3}{8}$ hole in a piece of hard wood, one inch thick and a foot long. I drop a piece of thick tin into this to form a resting-place for the spindle; and having got the pole plumb, I screwed this to the floor. I then put the pole through the wheel, the inside of the hub toward the bottom of the pole, and placed it in position. I next bored a hole 4 inches from the bottom, stuck the end of a ten-foot sash cord through it, knotted it, and attached a 3-inch ring to the other, and wound the cord around it to try how would work (see cut). The rest will be evident from the cut.

We will suppose a friend should call to see me during a honey season, and I should like to give him a taste of honey, none in the house. Well, such is my disposition that, if I had a regular extractor stored away, I would get it down to extract a single frame, to stand treat. Nearly the contents of a 3-lb. frame would stick to it, and a nice job to clean it, while the other can would not waste 2 ounces. Honey could be cleaned with a quart of water, and dried in less than half an hour.

Philadelphia, March 8.

S. STOUT.

Friend S., the arrangement you give is substantially very old. The "Rapid" honey-extractor, in the *British Bee Journal*,

some years ago, was on the same plan. While you can extract honey with such an arrangement, especially if you have a few hives, it is not only a very laborious way, but very fatiguing, where very much of it is to be done. It is true, that the honey is thrown into a single tin can, and nowhere else; but a single tin can can be used in any ordinary extractor, where you wish to extract only one comb, or, say, two combs, or more. The objection is, that it forms what is called a revolving-can extractor. The honey swings around with the comb, instead of being thrown out against a stationary can; and as soon as you swing very much honey in this way you will find it very laborious. Every comb that is emptied will necessitate stopping and pouring honey out of the can or cans. I would suggest that, if you are going to use such a machine, instead of a wagon-wheel and hickory sapling, you use simply a light iron or steel rod, with some kind of metal wheel not weighing over a pound.

GEORGIA FOR BEES.

AN A B C SCHOLAR'S EXPERIENCE.

ONE of my brothers has been keeping bees in this county for over six years, but he has never made bee-keeping a specialty. He commenced with only 13 colonies of the golden-banded Italians, and increased to 35 colonies, and sold \$335 worth of honey from them the first year. But as he has been engaged in farming and merchandizing ever since, he has not given them very much attention.

I believe this to be the best country for bees in the South, as we have a large number of honey-producing flowers in bloom here every month in the year, from January until November; and they are no trouble to winter.

Our winters are never cold enough to stop our bees from work. They usually commence to gather pollen in January, and never cease till December. The honey season commences about the first of April, and we take off surplus until the 15th of July. Our honey-producing plants and trees are the yellow jessamine, ground-huckleberry, gallberry, persimmon, magnolia, bay, poplar, and horsemint, and a large number of others whose names are unknown to me. Over two-thirds of our honey is made from the gallberry-bush, which commences to bloom about the 20th of April, and continues in bloom until the middle of June. Our apiary is situated in the center of a gallberry-forest, out in the country, three miles from Sasser, in

"A populous solitude of bees and birds,
And fairy formed and many-colored things."

And while the gallberries are in bloom the bees work from daylight until dark. It is in full bloom now, and it is a pretty sight to see how busy the little creatures are.

GALLBERRY HONEY.

This is the prettiest I ever saw. It is well flavored, very thick, and as translucent as the classic product of *Hymettus*. I took 52 pounds of as pretty sealed gallberry honey from an upper story yesterday as I ever saw, and I could easily extract 25 lbs. from any hive in our apiary. It is all this year's honey too. I expect to commence extracting in a week.

Mr. Root, I am one of your A B C boys, and will let you hear from me again soon.

WALTER L. ANTHONY.

Sasser, Terrell Co., Ga., May 6.

We have had of late some inquiry in regard to Georgia as a bee-country. The above will doubtless give the information needed.

HONEY-CIDER VINEGAR, ETC.

PUTTING REFUSE HONEY INTO THE VINEGAR-BARREL, ETC.

Dear Gleanings:—Your pages fall under the eyes of multitudes of people, embracing many shades of thought, and representing a great variety of interests. Though the chief interest centers in the busy bee, your readers are treated to other sources of vital interest to society, and to individuals. There really appears to be a great big GLEANINGS family who are all trying to help each other. The question, "What business shall we connect with apiarian management?" is a prolific one, and has had much interesting discussion in your pages.

I entered the GLEANINGS family in 1887, with 30 colonies; and however fascinating be the occupation, I need not even hint to any of those who record their honey gains in tons, how very essential a thing it is to us who would like to be bee men, to have a side show occupation until the big honey business would materialize.

In 1888 I moved my apiary from Indianapolis to North Vernon, Jennings Co., and to this city in 1889. Through these years and changes our honey product has slightly exceeded a liberal supply on my own table. My great lack of success has come from the ravages of that loathsome disease, foul brood. My stocks have decreased to 14 colonies, "spring count." I have just made a purchase of a fine old farm. Yesterday my little "wicked" busy bees bid good-by to city life, and to-day I liberated them under the spreading branches of an apple-orchard full of bloom; and this brings me to the thought which prompted this article. GLEANINGS is authority for the quality of honey vinegar. We are here surrounded by a prolific, never-failing fruit-crop. Fruit makes cider; cider makes vinegar; cider vinegar, known to be such, always commands ready sale at the best quotations. I put the question, "Will cider and honey vinegar combine?" Both are known to be in quality par excellent. Neither would be an adulteration of the other. The brand would be improved—honey-cider vinegar. I am told that honey enters largely into the manufacture of the plug from the wickedest weed in the world. Of course, the name of honey associated with the vile stuff helps the sale of it to those who indulge in such nastiness. Would it not be a humper in aiding the sale of pure vinegar? Can any one tell?

JOHN CADWALLADER.

Madison, Ind., Apr. 26.

Friend C., I am happy to tell you that we have been in the habit of putting our refuse honey into our cider vinegar for some time, and it improves it amazingly—sometimes to the extent of making it so sharp that nobody can use the vinegar without first diluting it. When they put it on the lettuce in our dining-room, I have remonstrated several times because they did not dilute it more. It would fairly take the skin off

your lips and tongue. Perhaps a better way would be to put water with the honey before it is added to the vinegar, to avoid having it too strong.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

A PASTE FOR STICKING HONEY-LABELS ON TIN.

In GLEANINGS for April 15 I noticed an inquiry for a paste to stick labels on tin. I find the following very satisfactory: Flour, 1 lb.; gum arabic, $\frac{2}{3}$ oz.; sugar lead, powdered, $\frac{1}{2}$ oz.; alum, $\frac{1}{2}$ oz.; water, 2 qts. The gum, sugar lead, and alum, are dissolved in the water, then proceed as when making ordinary flour paste. Scratching the tin with sandpaper, or washing with diluted muriatic acid, is also helpful. One of our amateur photographers likes this paste very much. J. F. BARTON.

Chicago, Ill., April 21, 1890.

And here are a couple more letters on the same subject:

You inquire how to make labels stick to tin pails. I have put on a great many this winter. The best way I find is to use common flour paste, well cooked, then rub the label hard with a dry cloth after it is on the pail; rub it down smooth, let it dry, and it will stay as long as the pail lasts, unless you wash it off. Mucilage will not stick well.

Jackson, Mich., Apr. 4.

W. D. SOPER.

To make labels stick to new tin with ordinary paste, rub a sliced onion over the tin.

Evansville, Ind., Apr. 17.

L. A. WILKES.

SPRAYING OF FRUIT-TREES AND KILLING OF BEES.

I write you for information in regard to the spraying of fruit-trees with poison. There are persons, malicious and ignorant, who will not yield to any proofs, but persist in spraying their trees while the blossoms are on, and poisoning the bees. One man in this neighborhood had his bees ruined for this season, and mine are dying off daily from the effects of poison. What I wish to ask is, whether there is any remedy through the law by which such persons can be made to quit it.

Milbury, O., May 2.

GEO. W. CHAPMAN.

Friend C., if your neighbors poison your bees they render themselves liable, in the same way they would if they poisoned your chickens or larger animals; and if it can be shown that there is no necessity for spraying the trees while they are in blossom, we shall have a pretty clear case against them. The professors in our agricultural colleges and experiment stations will back us up in the matter, and perhaps the Bee-keepers' Union may decide to take hold of it, if it comes to litigation. I would, however, have a friendly talk with your neighbors in regard to it, and show them what Prof. Cook has written on the subject.

DECOY HIVES NOT ALLOWED BY LAW IN CONNECTICUT.

There is a law in this State that makes the setting-out of a bee-hive in the woods, or anywhere else, for the purpose of catching runaway bees, a misdemeanor, punishable by fine or imprisonment. Now, what we should like to know is, can it possibly work

any injury to my neighbor who keeps bees? Does it in any way entice them to abscond? We claim not. But we claim, rather, it is a humane act; for why is it not better for the little fellows to have a decent place to set up housekeeping in than to have them waste their time and strength in cleaning out some old hollow tree? Now, I regard my neighbor's rights as sacred as my own, and more so. What we should like to know is, whether it can work him any harm to set out hives as I have stated. I hope you will not cast this aside without a reply. I think the law a foolish one, conceived in spite.

Middlebury, Conn., April 28. R. B. WHEATON.

Friend W., I was aware that such a law had been passed; but I pronounced it at the outset a foolish, unnecessary law, and I objected to it at the time it was brought up at one of our conventions. The enactment of such laws, where no law is needed, is one great reason why we have so many laws that are a dead letter. If I wanted to set out decoy hives in the woods or anywhere else, I would do so, and no one, surely, would make any complaint unless it would be some foolish fellow who has got cranky on the subject.

FOUR-BANDED ITALIAN BEES.

I send a sample of my "so called four banded bees." Will you please be kind enough to examine them carefully and tell the readers of GLEANINGS whether or not they have four or five yellow bands?

Frenchville, W. Va., Apr. 30.

L. L. HEARN.

Friend H., the Italian bees you send us in a Peet cage, mentioned above, when placed on a window, show distinctly four yellow bands. The fourth band is not the downy fuzz so often called a yellow band, but the horny scale of the body itself is, a greater part of it, yellow, just like the second and third bands in ordinary Italians. I do not know that I have ever before seen bees so distinctly marked with this yellow band. Some of them may also show the fifth band, but it is not as clear and unmistakable as the fourth. Perhaps I should say to our readers that I do not consider these extra yellow bands as particular evidence of their purity. It is doubtless the result of careful breeding and careful selection, having yellow bands constantly in view. While these yellow bands distinguish them more plainly than common Italians, from common bees, it does not necessarily follow that they are better honey-gatherers than ordinary Italians. The bees are of a good size, very handsome, and quite docile. I let them out of the cage on the window, so as to see the band more clearly, and put them back, taking them by the wings by my fingers, but none of them offered to sting. We should be glad to have friend H. tell us where he got the stock, and how long he has been getting the above result.

IN FAVOR OF OPEN-SIDE SECTIONS.

Seeing, as I do, in GLEANINGS, occasional and mostly uncomplimentary allusions to open-side sections, I feel called upon to say a word in their favor. During the season of 1888 I produced a little over 6000 lbs. of honey in open-side sections, $4\frac{1}{2} \times 4\frac{1}{2}$, 7 to the foot, and I was very well pleased with them. They were used in a case that clamped

them up firmly together, so that they were propolized only on top and bottom. This propolis was scraped off before removing the sections from the case. I think the trouble in using them has been that the case was not adapted to them. They must be clamped up tight together, so that no propolis can be got in between them. A T super will not do. I am not very much interested in this comb-honey business at present, as about a year ago I decided to run my bees—300 colonies—for extracted honey, yet I dislike very much to see a good thing, like the open-side section, defamed by those who have not given it a fair trial. T. P. ANDREWS.

Farina, Ill., May 5, 1890.

BAD BOYS, AND HOW THEY WERE SERVED.

I went into winter quarters with 119 hives; lost 20, and the boys upset six and rolled some down the hill, and killed three colonies for me. I sold nine others, leaving 87 colonies to commence with this spring, all in good shape, as they commenced breeding early in February and March, and are all getting strong now. The three boys that upset six of my hives and destroyed three, belonged to three different families; so I made their parents pay for the bees \$10 for each colony destroyed, \$30 in all, and settled it without going to court.

Norristown, Pa., Apr. 19. J. W. SWARTLEY.

Friend S., I think you did exactly right. Where boys tip over bee-hives, or destroy valuable colonies for the small amount of honey they obtain, I think the good of the boys demands they should be made to pay roundly for it.

A LOSS OF 110 OUT OF 161 PUT INTO WINTER QUARTERS, WITH THE DIFFERENCE GREATLY IN FAVOR OF CHAFF HIVES.

I have been watching to see the reports of the losses of bees this spring, but I have seen no report. I have lost 110 out of 161. I put 117 into the cellar. I left 44 outdoors in chaff hives, two of which died this spring. Most of those that were in the cellar were very weak. I set them out twice. There was a good deal of honey-dew last fall. It is cold and backward for bees. There have been big losses through this section. Some have lost more than I have. JAMES MARKLE.

New Salem, N. Y., May 1, 1890.

Your great loss in the cellar, and comparatively small loss in chaff hives, speaks well for the outdoor method, though the past open winter was much more favorable for outdoor wintering. We rather doubt whether the food was the whole source of loss in the cellar. Did your hives have plenty of bottom ventilation, and no top ventilation? Ventilation from an ordinary entrance in cellar is not enough. Another thing: Was your cellar darkened and perfectly dry, and did it maintain a comparatively even temperature? Let us hear from you again. We want to know more about your loss.

THE HOFFMAN FRAME.

Mr. Root:—The wide and thick top-bar is the only one that ought to be used in bee-hives. We have used such for six or seven years, and many near us are falling into line in regard to them. We did not like the brace-combs built above frames, nor the use of burlaps over them, neither the use of honey-boards. The frame we use is a trifle different from the Hoffman-Langstroth, but only in the width and

thickness of the top-bar. We call them the Hoffman-Langstroth. The use of wide and thick top-bars allows us to have no use for them, for we can use a plain board that comes off clean. Honey-boards, burlaps, etc., are too much machinery for us. You can do no better than the Hoffman frame, made as we make them. F. A. SALISBURY.

Syracuse, N. Y., Jan. 31, 1890.

You will observe that the frame he describes is quite similar to the modification we spoke of on page 330 of last issue. We are sure that bee-keepers would like to dispense with quilts, honey-boards, burr-combs, and "all sich," and we hope the above frame will enable us to do it.

HONEY-MOONS.

We extract the following from the *American Bee Journal*, as many, like ourselves, may not before have known the origin of the term:

Honey-moon, it is said, is a term of Teutonic origin, and derived from a luxurious drink prepared with honey by the ancients. It was the custom to drink of diluted honey for thirty days, or a moon's age, after a wedding feast. It is good to "keep sweet" for a month after marriage; but it is better when that "sweetness" extends throughout not only the months, but the long years of wedded life.

We heartily indorse friend Newman's closing sentence.

BEES CLUSTERING ON THE EAST SIDE OF THE HIVE.

In examining my bees last week I noticed that in all the four hives the bees were clustered on the east side of the hive. Is this usual? I winter out of doors on 8 S. frames, stores on each side of the cluster, 4 frames with the bees in center, 2 frames of honey on each side of cluster. J. F. BARTON.

Chicago, Ill., April 21, 1890.

Friend B., if what you say is true it is because the morning sun has so warmed up your hives as to call the bees over to that side. I have seen them cluster on the south side of a hive in preference to the north, and for a similar reason.

DOUBLE-TOP-BAR FRAMES.

On page 204 is illustrated and described a double-top-bar frame; and in our answer we refer to a sample which we held in our hand, and which, by propolis accumulations, we judged had been used for some time. At the time we did not know from whom it came. The letter, with reference to it, was attached to an order; and as it is now separated we take pleasure in presenting it to our readers. Friend Penton was among the very first to use the double top-bar—perhaps the first.

Friend Root:—I send you by mail one of my thick-topped frames, to let you see that there is in practical operation a deep top-bar combining all the advantages called for by the fraternity, unless it be in the width. I have adopted this for the purpose of making more distance between the brood and the upper frames, or sections, the prevention of brace-combs, and the necessity of a honey-board. The queen will never trouble the upper story. The bees will not pile up the bee-space, and, summer or winter, packed or unpacked, the bees have free access to all the combs in the hive. I am aware that, if the top-bars were all of one piece, and cut out

with a wabble saw, they would be stronger and better, but I have no machinery for doing it. I am sure you could sell any amount of them if you made them.

CHAS. PENTON.

E. Aurora, N. Y., Feb. 2.

Your suggestion is no doubt valuable. I hold in my hand a top-bar made as you suggest. Instead of using a wabble-saw we simply use one of our thick grooving saws. A slot is cut so as to leave sufficient wood at each end, and also a solid piece in the middle. Yours will be the cheapest way to make a double top-bar; and it will, besides, be considerably stiffer than one made of two pieces of wood.

A LETTER FROM A LITTLE GIRL; PAPA'S SOLAR WAX-EXTRACTOR.

My papa had over 70 hives of bees two years ago. I will try to tell you how we moved them. He filled the horse-cart nearly half full of fine dirt, so they would not be jolted, then placed in as many as the cart would conveniently hold, brought them home, and removed all the others the same way until all the bees had arrived safely at our new home. Papa does not "squeeze" the cappings, as some do, but he has an extractor made of a Simplicity hive with a flat cover put on, on hinges, then in the bottom there is a square tin pan 6 in. deep, which catches the

wax and honey; above that there is a wire-net cover on which the wax is placed. The good goes down in the pan beneath, while the dead bees and old wax stay on the wire net, and over that there is a glass cover which throws the heat of

the sun down on the wax, and melts it very rapidly. I here draw one as near like it as possible. Papa gives me half of the wax for watching it, and putting and taking out wax when it is needed. Once a high tide came half way up our front yard, and drowned nearly half of our bees.

Church Creek, Md.

ELIZA BUSICK, age 12.

MOVING BEES; BAD WORK WITH.

I must give you the benefit of my experience in bee culture. It was many years ago, when I was but a young lad, when a man who kept a number of hives was a laborer for my father. He would be talking everlastingly about how all his bees were thriving. I purchased one hive from him, and left it with his own for two or three years, when the number was increased to six or seven, and may be eight hives. I made as many stools in my father's kitchen garden to place the hives upon them. I inquired of the bee-keeper the best way to remove them. He said, "The road is good, as smooth as a room floor. Bring a large-bottomed cart and towels, and we will fix a towel about each hive, and place them all in the cart; and by driving carefully you will get them home nicely." Home was three miles off. By the time we had gone but half a mile, the honey was dripping through the cart on the road; but as it was useless to stop, we continued our journey. Upon lifting them out of the cart to place them on the previously prepared stools, the

works were detached from the hives (made of straw); only two or three could be set on the stools; the rest were all broken-up wax, honey, and bees, all thoroughly mixed up. After getting the household bedded, I placed two washing-tubs before the kitchen fire, took off my coat, rolled up my sleeves (I had been, previous to that, stung so much that I had become heedless of more), took up a handful of the mixture, and picked with my fingers bee after bee into the fire. This was my occupation all the night, and I finished it only when the sun was rising. You will doubtless laugh, but I tell you it was not a laughing job to me at the time, though I have laughed over the matter many a time since.

Washington, D. C., April 10.

J. S.

But, friend S., what in the world did you sit up all night for, picking out bees and throwing them into the fire? Did the mashed-up honey you had, pay you for the trouble? It was the towels over the bottom of the hive, shutting off the air, that made the trouble. In removing bees, you want wire cloth. Nothing else is safe, especially when the weather is warm.

WHAT MADE THE BEES SWARM OUT?

My bees have been out for a week, and I have had 7 swarms leave their hive and go in with other swarms. They leave from 20 to 50 lbs. in a hive.

Hammond, Wis., Apr. 4.

A. E. BRADFORD.

The swarming out you mention comes under the head of "Absconding in Early Spring," in the first chapter of the A B C book. Bees are more apt to do this when wintered in cellars or special repositories. Yours must have gotten a kind of absconding mania, especially if they had plenty of stores, as you state it.

FALL HONEY, AND BEES IN GOOD CONDITION.

Bees did not do much last year till about September 1, when the fall flowers opened and the bees went at them in earnest, filling their hives with the best fall honey I ever saw. I had several swarms in September, which built their combs and stored honey enough to carry them through the winter—something never known in this country. I have 50 colonies of bees in good condition for spring work.

Mart, N. C., March 17.

SUBSCRIBER.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

QUESTION 160.—A young man having just graduated from college, and living in the vicinity of Central Illinois, has had some experience in managing out-apiaries for a bee keeper. He desires to keep some two or three apiaries, and teach school during the odd months. He wants to know how much time he will probably have for teaching school, providing he does all the work himself, with the assistance of a horse and wagon, and yet give the bees all the necessary attention.

I should think about four months.

Cuba.

O. O. POPPLETON.

Excepting a few days, he will have from September 1st to April 1st.

Wisconsin. S. E.

GEO. GRIMM.

If he purchases all supplies, six months, from October 1st to April 1st.

Michigan. C.

A. J. COOK.

He would "probably" know if he should follow out his proposed plan.

Ohio. N. W.

A. B. MASON.

I should say six months, if his apiaries do not exceed 100 to the apiary.

California. S. W.

R. WILKIN.

Not a day—at least I suspect that from my own experience, unless the apiaries are very small.

Illinois. N.

C. C. MILLER.

If by the above is meant during the honey season, none. If the entire year is included, probably from five to six months.

Illinois.

MRS. L. HARRISON.

If he makes his own supplies, I should say, "Not any." If he buys his supplies, then perhaps three months during winter.

New York. C.

G. M. DOOLITTLE.

If he keeps two or three apiaries, and gives them the necessary attention, it will take more of his time than he will be able to give to a school.

Louisiana. E. C.

P. L. VIALLO.

If he works with his bees every Saturday he will be able to care for two or three apiaries during the school months—we mean from September till May.

Illinois. N. W.

DADANT & SON.

In a year or two he will probably have twelve months for teaching. With the amount of work he lays out he can do neither himself, school, nor bees, justice, and one or all will fail.

New York. C.

P. H. ELWOOD.

If this young man is full of energy I should say he might devote three or four months in winter to teaching at first. He can then decide the question for himself.

Ohio. N. W.

H. R. BOARDMAN.

If he has steel nerves and is iron-clad, and requires no rest, he may teach from December till March; but if he is of the same material as other men, he will have no time to teach and do justice to his bees.

Vermont. N. W.

A. E. MANUM.

If he keeps "two or three" out-apiaries of a proper size, doing all the work himself and doing it properly, he will probably not be able to teach school more than nine months in the year. Most men would not have any time for school-teaching.

Illinois. N. C.

J. A. GREEN.

I think the young man will find that the schools will claim to set the time for him. He will have to push things to get ready to begin the fall term; but I guess he can manage it if he uses his Saturdays to finish up in. The winter term will come all right. The spring term he can hardly take, unless he can find a school accommodating enough to have an unusually short spring term. Thus six or seven months would be his outside lines.

Ohio. N. W.

E. E. HASTY.

He can teach during the winter months. Begin, say, November 1st, and teach four months. But if he keeps two or three apiaries of from 60 to 80 colonies, spring count, he can not do all the work himself during the honey season; and then when he gets his third apiary to going in good shape he will find that his school days are over, for there is a great deal of work that can be done in the winter—

getting things ready for next year, and selling off his honey, etc.

Wisconsin. S. W.

E. FRANCE.

I don't think I would teach any, unless I had to. He might, perhaps, be able to teach the winter months if he buys his hives and fixtures, but it would be well for him to get thoroughly rested during the winter; for if he runs three yards with 100 colonies each, he will have to get around pretty spry during the bee-season if he gives the bees all necessary attention.

Wisconsin. S. W.

S. I. FREEBORN.

Let us see. Three apiaries, 100 colonies each, 300. If run for comb honey there will be somewhere near 20,000 sections to prepare, besides hives and many other things. We should therefore say, that, doing all this work himself, there would be but little time for "swinging the birch." If, however, the bees are run for extracted honey, and after each hive has a complement of extra combs and no increase allowed, then from November 1st until April he could devote his time to the profession of pedagogics.

New York. E.

RAMBLER.

Now please excuse me for the following reply, because I feel sure you want the truth as I see it. In the first place, this young man's having graduated from college is no sign that he is as well prepared to manage your bees as some young man who has not been to college. In the next place, he does not look upon bee-keeping as I do, if he proposes to manage two or three apiaries and teach school during the "odd months." If he does the work as it should be done, he will have no "odd months" at all, if each apiary contains a sufficient number of bees to be worthy of the name of apiary. In taking bees on shares there is an enormous profit to him who takes them, and a loss to the one who owns them if they are worked on the "kick and a brush" plan. Whoever works apiaries, whether he owns them or not, should do the work well and carefully, seeing to every detail, and should have all of his work done ahead of time. If you aim to keep from one to two weeks ahead of your bees you will probably not get behind at any time; but if you aim to keep just even with them you will probably get a week or two behind just at the time when the greatest loss from such being behind comes in. I want the hustling fellow, with natural ability, and I don't suppose it would hurt him if he had graduated at a college, provided his metal had not been all molded and worked in that college until the temper is all worked out of it.

Michigan. S. W.

JAMES HEDDON.

I am much inclined to agree with the friends who think that he should not teach school at all, or else he should not keep bees at all (of course, there are men who can carry on two lines of business at once)—that is, if he wishes to attain a great degree of excellence in either calling; and it seems to me, too, that this young man is starting out pretty large. If I understand him, he has not had experience in handling even one apiary of his own. The man who proposes to keep two or three out-apiaries, even after he has had experience, will find enough on his hands to occupy all his brains and energies, even in winter time.

ANSWERS TO QUESTIONS

FROM OUR A B C CLASS.

This department is designed primarily to cover questions either not already answered in the A B C of Bee Culture (price in cloth \$1.25), or, if incorporated in this work, are here dwelt upon more in detail on account of the importance of the question. While these answers are of vital interest to the A B C scholars, they will doubtless be found, in many instances, to be of considerable value to the more advanced student. For lack of space, the question itself, instead of being directly stated, is omitted, the same being implied in the answer. It is hoped that the class will first consult their text-book before sending in their questions.

MISTAKEN IN STORES.

J. W.—The boy was probably mistaken as to the amount of stores the bees had. They should have had twenty pounds by weight. It is well for beginners to weigh the combs. If the aggregate will make twenty pounds, all right. If not, feel until they have enough.

SHUTTING BEES IN CHAFF HIVES DURING WINTER.

C. P.—Do not shut bees up, packed in chaff, outdoors. Give them a full entrance, and let them fly when they will. You may kill them if you keep them shut up. Bees that die in the snow, probably are of not much use to the colony. They are diseased, and hence fly out.

ARTIFICIAL FORAGE.

J. H. I.—It will not pay you, if you are a beginner, to plant for bee-forage. But very little is gathered, usually, from artificial forage. Natural sources are usually depended upon. Alsike clover, buckwheat, and rape, are usually safe to sow. See "Artificial Pasturage," in the A B C book; also "Alsike," "Buckwheat."

MARKET VALUE OF DARK HONEY.

Miss H.—Dark-colored honey never sells for as much as light-colored. As a general thing it will not bring much more than half; 25 cents at retail certainly would be very high for dark honey, especially if the flavor were of an inferior quality also. The best way to dispose of candied comb honey is to feed it to the bees.

ABOUT WHEN A SWARM MAY BE EXPECTED.

H. G.—You can not tell exactly when bees will swarm; but from conditions in the hive, you can say they will swarm in a day or so *perhaps*. The conditions are, an overcrowded hive, large amount of brood, several queen-cells which will hatch in 24 or 48 hours, and a good honey-flow. See "Swarming" in the A B C book.

PROXIMITY TO THE HIGHWAY, FOR BEES.

C. W. Y.—The outskirts of the apiary should not be closer than 100 feet to the highway, and on account of the children it would be better to have it that distance from the house. With a high board fence, or a hedge six to eight feet high, the apiary may reach clear up to the highway, and very little trouble, if any, will be experienced by passers-by.

SENSE OF HEARING NECESSARY OR NOT FOR A BEE-KEEPER.

A. T. G.—Impaired hearing would have very little to do with your failure or success as a bee-keeper. The only difference, and that would be slight, would be that you would sometimes be unaware of the issue of a swarm, from your inability to hear the swarming-note; but by keeping on the watch during swarming time, as every bee-keeper should, you would lose few swarms. Again, you might miss some of the pleasures of a bee-convention. One of

the best bee-keepers in the State of Ohio is hard of hearing.

TOBACCO COLUMN.

CONDITIONS UNDER WHICH WE GIVE SMOKERS TO PERSONS WHO STOP USING TOBACCO.

First, the candidate must be one of those who have given up tobacco in consequence of what he has seen and read in this department. Second, he promises to pay for the smoker should he ever resume the use of tobacco in any form, after receiving the smoker. Third, he must be a subscriber to GLEANINGS. Any subscriber may, however, have smokers sent to neighbors or personal acquaintances whom he has labored with on the matter of tobacco-using, providing he give us his pledge that, if the one who receives the smoker ever uses tobacco again, he (the subscriber) will pay for the smoker. The one who receives the smoker in this case need not be a subscriber to GLEANINGS, though we greatly prefer that he be one, because we think he would be strengthened by reading the testimonials from time to time in regard to this matter. The full name and address of every one who makes the promise must be furnished for publication.

A MINISTER WHO USES TOBACCO.

I enjoy Our Homes very much. It is all written in such a practical way, just like the experience of so many others, that it is of great help to resist temptations. I have had a temptation all my life—that of smoking. Although, through the careful training of parents, I never used tobacco in any form, yet there is still a desire for it. Now, while I believe we should have a great deal of charity for the failings of others, when a servant of God who sets himself up to teach others the truth and *purity* of the word, one can hardly tolerate the use of tobacco. A minister of this class called at our house, and during the time he was offering up prayer and thanksgiving to God, he was compelled to stop three times to expectorate the vile quid. Now, this seems pretty hard; but still it has its influence on others by disgusting them. But, friend Root, what ought one to say to such a person? God hasten the day when tobacco will become extinct.

Linn, Kansas.

J. T. VAN PETTEN.

Friend V., I can not tell you exactly what you ought to say to a minister who persists in the use of tobacco; but I would say, in general terms, try to say that which will do the most good and not do him harm. Pray for him, and pray for yourself before you say anything, and ask the Holy Spirit to help you to act and speak wisely. With such a preparation before you, you will be very unlikely to do harm. But even if he does not stop forthwith, give him to understand that you consider him a brother still. And let us remember that it is everybody's privilege to do as he sees fit or thinks proper, in all these matters where there are differences of opinion. In returning from a convention in Michigan I rode several hours in the night with a good brother who is a professor of religion, but who acknowledged to me that he used tobacco, and either could not or had not given it up. His son in the seat with him listened to all our talk. I told him I should pray for him, and told him that it would be good news to me at any time to hear that he had, with God's help, broken away from the bondage. In a few months the son wrote to me that his father broke right square off shortly after our talk. I am now waiting anxiously to hear that the son has come out before men and confessed Christ Jesus. May be when he reads this he will gain courage.

THE FUN IN QUITTING TOBACCO.

I have used tobacco 20 years. I have quit using it. I have not used any for over three years. I now propose to handle bees for 20 years, and see which is the most profitable for me to handle—bees or tobacco. If you have never used tobacco you don't know the fun there is in quitting it.

Athens, Pa.

JULIUS WHITE.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO-RAISE CROPS.

That art on which a thousand millions of men are dependent for their sustenance, and two hundred millions of men expend their daily toil, must be the most important of all—the parent and precursor of all other arts. In every country, then, and at every period, the investigation of the principles on which the rational practice of this art is founded ought to have commanded the principal attention of the greatest minds.

JAMES F. W. JOHNSTON.

HOW TO MAKE PLANT-BEDS ON THE WORST KIND OF GROUND.

In our last issue I promised to tell you how to make plant-beds on the worst kind of ground. Keep on just as I have directed before. Now, no matter how much under-draining you have done, you want over-drains, or surface-drains. J. M. Smith had them in his beautiful sandy soil at Green Bay, and I am sure we want them everywhere. For the plant business I would have these surface-drains $3\frac{1}{2}$ feet apart, from center to center. These surface-drains also form paths to walk in as well as to carry off the surplus water. We make them with two horses by means of Darnell's furrower and marker. Our machine leaves the ground something like the diagram below.

HOW TO MAKE YOUR PLANT-BEDS.

A A are paths, and B B the beds. The machine leaves the ground as we have shown it on each side of C. D D shows the fine soil scooped out of the bottom C. This fine soil is leveled down and brought into shape by a machine of my own invention, illustrated below.

MACHINE FOR MAKING BEDS FOR VEGETABLE-PLANTS, FLOWERS, ETC.

The runners of this sled arrangement are to go in the paths A, A, in the diagram

above. The sieve or screen is just the kind they use for screening sand, gravel, etc. It is set at such an incline that, when the soil of the bed is thrown on top of the screen, the fine dirt and fine manure will go down through, while the rough part slides down to the ground at G. Here we have small stones, clumps of dirt, chunks of manure, weeds, sticks, trash, etc. The meshes of this screen are $\frac{1}{4}$ inch; that is, there is a $\frac{1}{4}$ -inch space between the wires. The operator scoops out the soil of the bed, and throws two or three shovelfuls on the screen A. Then with his foot and shovel he levels off the coarse part at G, takes hold of the bail C, and pulls it along, say a foot, then shovels some more dirt, and pulls it along, and so on. The result is, that the surface of the bed is soft fine soil down several inches, and it is finer and smoother than any soil you ever got by raking. If your ground is in very good order, you may have four or five inches of this beautifully fined-up soil, most thoroughly mixed and mingled with all the manure that has been put into it, and the big lumps and trash are all down beneath. The back end-board, D, as the machine is drawn along, smooths the surface so it should be almost or quite ready for the plants. Our engraver has left the surface of the beds rounding, where they should have been flat. The paths, or surface-drains, are rounding, or hollow, while the beds are perfectly flat, as shown in the diagram. This apparatus not only does the work very much faster than it can be done with the garden-rake, but it leaves the soil in a much better condition for the plants. I have been astonished at the enormous productiveness of these plant-beds when the weather has been favorable. A man, or even a boy who has had a little practice, will go over the ground very rapidly. When the paths get weedy, get your marker and draw over it with a team, and they will be scraped out most beautifully.

For planting cabbage, celery, and every thing of this description, we take a roll of poultry-netting, the exact width of the top of the bed. This netting is ordinarily of 2-inch mesh. For the celery, we have used $1\frac{1}{2}$ -inch mesh. Unroll it, and then roll it up the other way, so that, when laid on the ground, it will lie flat. Make it stay by means of some bricks laid on it, wherever it bulges up. Now give the boys an ordinary cheap wooden sled that will just span the beds. When one of the boys is working, he can sit on the sled and put the plants between his feet. We ordinarily, however, have two boys work together. As the plants are put in, their sled, or seat, is pulled along. If the weather is hot and dry, a barrel of water and watering-can should be right beside them. While I write, at least a dozen schoolboys are busy putting out celery and cabbage (a plant in each opening), for we had a nice shower last night.

Now, before you say it is too much fuss and trouble, and will not pay, just remember what I told you before; and I feel sure that it will prove true in almost any locality. When you get your piece of ground up to its highest notch of fertility, the prod-

uct of a square yard of your beds in *four or six weeks'* time *may* bring you a dollar bill. But even if it brings you only 25 cts., just figure up what a quarter of an acre will amount to. This ground, worked on the high-pressure principle, using guano and liquid fertilizers, should be bearing crops of some kind from the first of April to the first of October; and with the aid of glass to keep off the frost, it can be growing a crop every month in the year. You may take exception to some of these statements; but if you do, I shall tell you that you *never saw* a square yard of ground doing what it is *capable* of doing; in other words, you have no comprehension of *God's gifts* to the diligent *lover and searcher* in this direction.

A MACHINE FOR SORTING POTATOES.

For two or three years past, we have been sorting our potatoes with a sieve covered with poultry-netting of the right size of

through the *Rural New-Yorker*. That inquiry brings to light the machine we illustrate below.

You see, these friends have gone ahead of me in making it in the form of a revolving cylinder. Here is what they say about it:

You will notice at once that it's "just the thing;" "wonder some one hasn't thought of it before." Well, here it is now, and at a price within the reach of all. With this machine, which weighs less than 100 lbs., two men and a boy can sort and put into the wagon from 80 to 100 bushels an hour. It can be operated by one person, if necessary. As you see, the potatoes pass from the hopper into the cylinder, which should be turned very slowly, by a lazy boy; and if he has got the "spring fever," so much the better. Have him pick out the decayed or scabby potatoes as they pass through the hopper, otherwise he will want to go to sleep. If the potatoes need sprouting, raise the lower end of the machine, or turn the cylinder half way over and then back, or both. The small potatoes, dirt, straw, etc., will fall under the sorter into the basket, while the merchantable ones will be delivered into baskets as shown, or they may be run on an incline into the

THE HOOVER POTATO-SORTER, MADE BY HOOVER & PROUT, AVERY, ERIE CO., O.

mesh. The way we used this sieve was to place four bushel boxes tight up together. The sieve was laid on top of these boxes, and about a bushel of potatoes poured in. Then a boy at each side would shake them until the small ones had passed through. The large ones were then poured into two more potato-boxes, placed side by side. This was a good deal faster than sorting them by hand, and there was not any guess-work about it. All that went through the meshes were sold at a low price. I soon made up my mind that a machine was needed to do it faster and with less labor. But the more I thought of it, the better I became satisfied that some competent person should take the matter in hand, and, by means of a series of experiments, work out just what was needed. I then had in mind a sieve suspended so as to oscillate, letting the potatoes roll off the lower end. With a view of finding out whether any such machine had been made, I made inquiry

cellar. To sort seed potatoes from the small ones, just wind the cylinder with binder twine the proper mesh, and the result will surprise you.

We have been using one of the above machines for two or three months past. I had not thought of having a sprouting-machine to take the sprouts off; but this machine actually does it pretty fairly. To keep the potatoes from flying around the room we have tacked on a couple of side-boards, reaching up about as high as the top of the reel; but we greatly prefer to have the bushel boxes instead of the baskets, as shown in the cut. The boxes can be placed under the machine, pushed up so tight together that no potatoes, dirt, or rubbish of any kind, can get out on the floor. The price of the machine is \$15.00.

SOME HINTS ON RAISING ASPARAGUS.

Friend Root:—As you are very fond of gardening I thought I would write you a treatise on asparagus, as it is but little cultivated, and one of the best of vegetables, coming in early when there is but

little else in the vegetable line to be had. The seed can be obtained from the leading seedsmen, and planted in a great part of the U. S. in May. In the fall and early winter, the seeds, when mature, can be gathered, and they are easily cleaned by putting them into a vessel of water and rubbing them with the hands, when the seeds will settle to the bottom, and the hulls, etc., will come to the top, and can be dipped or drained off, leaving the seed nice and clean. Plant the seeds in April or May, according to climate, in rich mellow earth, about an inch deep, with the seeds two or three inches apart in the drill. Keep them well cultivated for one or two years (two years give the best roots), when they are to be reset in very rich land (unusually well enriched), some time before resetting; the roots are to be put out in trenches somewhat below the general level, and a slight ridge, or bed, is to be made over the roots, and these beds, or ridges, must be kept free from weeds and grass. The plants ought not to be cut or used the first year, or the same year that they are reset. Fertilize annually, and the planting will last for a lifetime, or a good many of them, doubtless. They ought to be reset in the trenches or rows at least one yard apart. A table-spoonful of seed will raise plants enough for a good-sized family. It is a salt-water plant by nature, hence light applications of salt promote the growth of the plants, and also help to keep down weeds and grass.

R. JONES.

Design, Va., April 28, 1890.

Thank you, friend J. Our experience is rather limited in raising asparagus, but we have found this true: There has never been a surplus yet in our market. Last season we cut continuously from the first of May till the first of July, and some even later; but the plants seemed just as thrifty this year as ever. Two years ago we ran our little seed-drill twice the length of the field, but sowed seed pretty thickly, for the plants in some places were less than an inch apart. Since then we have done nothing but run a cultivator each side of the row, and hoed them out two or three times; and this spring, from those two rows, we have sold certainly \$25.00 worth of roots. It is almost the only vegetable with which we have never yet succeeded in overstocking the market.

OUR HOMES.

But the water that I shall give him shall be a well of water springing up into everlasting life.—JOHN 4: 14.

Most of you know how much I love to see springs of water. Hunting for springs has been one of the hobbies of my busy life, especially if the springs are perpetual, bubbling forth their treasures winter and summer, year in and year out. Where water is plentiful, we think little of its value. I was greatly pleased in California, and along the desert wastes, to see how much value was set upon a living spring. Even if the water that is poured forth is but small in quantity, if the little stream keeps running winter and summer, in the course of time it amounts to a great deal; and there is something pleasant and fascinating

to almost every one in seeing the water spring forth, and keep running unceasingly. My friends laugh at me because I go up on the hill so often to see the windmill raise its treasures of water. When I am tired of reading your letters, I look out of the window just as I am looking out of it now while I dictate this, and see the beautiful piece of machinery raise its burden of pure water from the depths below. Although it has pumped more than 500 barrels a day, there has never been any indication of the well giving out, and the water has already acquired the reputation of being the best drinking-water in the town.

For a week back, our wood-working factory has been humming and buzzing through the night time as well as through the day. As we started up suddenly, to try to fill your orders by working both day and night, we were obliged for a time to use coal-oil lamps to light the workmen. The question was asked whether I dared to take the risk of getting our whole establishment burned up, as was that of friend Lewis. I replied that I had very little fear while the sprinklers covered every foot of space right over the work, and so long as the windmill kept the great tank full of water; for such an abundant supply of water, springing forth at the first start of the fire, must necessarily drown it out before it could make any headway. Am I getting away from my text? I hope not, dear friends, for I have been thinking that this perpetual spring of water is to our business like the follower of Christ in any community where there is danger of the fires of sin drowning out all that is good. The woman told Jesus that the well was deep. She seemed to think the waters of that well that had quenched the thirst of Jacob and his children, and their generations all along down, was one of the great essentials in their time, and so it was. But the Savior next told her of the living water; and he said it should be in the heart of the possessor like these *living springs*, and that it should refresh and invigorate all around by its unceasing supplies that should give everlasting life. Dear friends, these words are more true than perhaps you and I shall ever know. As we go on and persevere in the Christian life, we shall know more and more of the value of these waters, and their power to refresh, awaken hope, gladden, and give joy, until that everlasting life beyond shall be the end.

We are greatly inclined to forget this promise. This fountain will be neglected and choked with worldliness if we do not look out. Then, perhaps, we shall look back to the time of our conversion, and lament that the pure waters are not *now* springing forth as they did then. But it need not be so, dear brother and sister. It may be, and should be, as in the text, a well of water springing forth and giving hope and joy and everlasting life to all around.

Through all my religious experience I have been in the habit of expecting, day by day, *fresh* experiences welling forth from my heart—something new, joyous, and refreshing, coming, as it were, of *itself*—burst-

ing forth without any agency of my own, and giving me something fresh, bright, and new to give to my friends all around, to cheer and encourage them, and to revive and refresh their hopes and their faith. This thing of which I have been speaking has been one of the joys of my life, and I have been led to expect it. But let me tell you that this fountain is easily dimmed and choked up, if I do not constantly beware of the tempter. The experience I spoke of a few months ago, where Satan for a time bid fair to get a foothold, for a time checked or kept back these experiences. I knew it would be so; and when he was trying to make a barter for something he had to offer, over and against everlasting life, one of the things that kept me back was, that I knew I should soon lose these bright experiences of that living water, coming forth, oftentimes, when I least expected it. "Ye can not serve both God and mammon." If I listened to *him*, I knew I should have to abandon all at once. And yet I did not get away from him easily. He followed me days and nights. He tried first one thing and then another; and even after he seemed to have *abandoned* his undertaking, he would come back now and then. I hardly need tell you that the one who expects to do spiritual work—who expects to be successful in bringing souls to Christ, must be wholly in the service of the Master. There can be no half way about it.

For some time I had been feeling that my gift, if that is the right name for it, in presenting the cause of Christ to my friends and acquaintances, was being drawn gradually from me; but when I turned resolutely about, and prayed earnestly, alone by myself, it has come back again; and within a few days these experiences that I have been telling you of have been coming thick and fast; the shackles and fetters have fallen away, and Satan has no power, and my spiritual vision is undimmed and unclouded, as in the time of my first turning to the Lord. Now, when we feel that this well of water that should *constantly* be in the heart of every Christian seems in danger of drying up, or ceasing to give its accustomed light-heartedness and bright faith, what should we do? And it is this thought that has prompted this paper to-day.

One who would have this living water springing up in his heart must first acknowledge God the creator of all things. A friend of mine who lives in California wrote some time since something like this: Said he, "If I were a praying man I would thank God every day of my life for this beautiful climate, for my growing crops, and pleasant surroundings, etc." I wrote back to him not to wait till he was a praying man, but to commence thanking God right away, and to do it out loud. I tell you, my friends, it is a grand thing, many times, to speak out plain and clear; and it is a grand thing to acknowledge your Creator and the great Judge of all the earth, right out loud. I told this friend, the next time he went out over those wonderful hills after his horses, in the bright morning, to begin speaking loud to the great God above, and to give him

thanks and praise. Dear readers, if there are any of you who feel like this one of whom I have just spoken, try the experiment. When off alone by yourself, give praise to God. It will help you in a great many ways. First, you are acknowledging and paying respect and deference to the great Ruler over all; second, you are getting a start in being thankful to somebody. A human being who has no thanks to give to anybody—not even to God the Father—is in a deplorable state of mind. When you get in a way of thanking God, you are very likely to begin to feel like thanking friends and your neighbors when you meet them; and a man who has thanks to give to each one, and who *feels* thankful, is a gainer in a great many ways. He will get more of every thing good by having thankfulness and thanksgiving in his heart. After you have for some time become accustomed to thank God in your fashion, and after your own way, you will be pretty sure to begin to think of texts of Scripture right along in this line. How full are the Psalms of David of such expressions! When David was a shepherd-boy, off in the fields with the sheep, alone by himself, oftentimes with only the stars above him for company, he learned to give thanks. While I dictate I open the Bible at random. The Psalms are pretty nearly in the middle of the book. The first thing that meets my eye is this:

O Lord, my God, in thee do I put my trust.

And after this comes a prayer:

Save me from them that persecute me, and deliver me.

On the same page I read:

O Lord, our Lord, how excellent is thy name in all the earth! who hast set thy glory above the heavens. . . . When I consider thy heavens, the work of thy fingers, the moon and stars, which thou hast ordained, what is man, that thou art mindful of him?

If you have never loved the Bible, when you commence giving thanks to God you will find in it something that harmonizes with your feelings. Perhaps you will remember the prayer that Jesus uttered—"Our Father who art in heaven." And then how naturally comes the next—"Hallowed be thy name!" Why, as you utter these words and feel this sentiment in your heart, you will stand more erect, you will have a broader view of the universe, mankind included, and you will feel more like being honest, good, and true.

When you have learned to love God, and to love these Bible texts that speak of him—when you have learned to pray, even after the humble fashion I have indicated—you will begin to feel Satan striving to draw you away from sacred and holy thoughts. This new joy of yours can not be a well of water springing up into everlasting life until you begin to put aside self. These feelings of gratitude that bring joy and gladness will be dried up, and will soon be quenched if you give way to the temptation to wrong or to defraud your fellow-man.

You may dishonor the Master in a very small matter of business deal; and when you do so, this avenue is choked. It is hard to realize how exceedingly careful we

should be. Let me illustrate by a little incident. I tell it because I wish to show you how to keep the fountain flowing, and not because I wish to praise my own acts.

A man brought us some bees this morning. He made the remark that he got acquainted with A. I. Root a good many years ago. When asked about it he said something as follows:

He said he once had some bees to sell, and he was going to bring them out to us. One of his neighbors remarked that A. I. Root always did exactly as he agrees. He replied:

"I know better. A. I. Root does *not* always do as he agrees."

"How so?" was the reply.

"Why," said he, "he agreed to give me \$5.50 per colony for some Italian bees. On the strength of this I drew them out to him; and when he saw them he did not do exactly as he agreed, for he gave me \$6.00 instead of \$5.50."

Now, I have forgotten all about the transaction. I can only remember that, at different times, I have enjoyed doing business in just that way; and a great many times I have been glad of a *chance* of doing it, because such things honor the Master, and I always feel happy afterward.

If your money-getting, and getting ahead of your neighbor, are dearer than your love to God, this living fountain must cease for ever; and by and by it becomes a daily task to keep out the weeds of selfishness, and to keep unobstructed the passageways for God's love to come into your heart. Jesus strikes the point where he says, "If any man will follow me, let him deny himself and take up his cross daily, and follow me." You can not have this constant enjoyment otherwise. Lately I have learned particularly to enjoy going to sleep at night with a conscience void of offense toward my fellow-men. I have had some experience in going to sleep with the guilty feeling that I was cherishing, or coveting, something that was not lawful for me to have. Then this spring of joy was choked; my spiritual life was clouded; and when awakened in the morning, my mind would begin to grope for some dreaded remembrance. And, oh what a feeling it is to be obliged to face the recollections of guilt and shame of the day before. Now, let us contrast the joyous feeling of being able to look over the record of the day before, and find it clean. For a few months my first conscious thoughts have been something like this:

"Let me see; is there any thing on my conscience this morning, to mar the new day? Did I cherish evil and iniquity in my heart?" As memory brings up one after another incident, are there any great black spots—any great loads or burdens of sin that I must shoulder to-day—any remorse and regret because I have turned from the Savior and listened to the tempter? Perhaps it takes only a few seconds to review the day before; but, oh what a glad feeling comes when I can say there is nothing to feel bad about! I often feel to say in my heart, "Thank God, thank God, there was nothing when I closed my eyes in sleep last

night to make me feel guilty and wretched this morning. I fought the good fight, and by the help of Christ Jesus I came off triumphant." Now, when I do commence in this way I am sure to have those experiences I have told you of—thrills of joy and thanksgiving—thrills that come along in the line of some remembered text that I never thought of before.

This is Monday morning. Last Saturday night we all sat up rather late in planting our new dynamo, and making attachments to the electric lights, so they would be ready to illuminate the saw-room at one o'clock this morning. When the expert who was putting up the plant announced that all was ready, we stationed ourselves in the room, which was pitchy dark, while he turned the lever and sent a current through the wires. In an instant the room was in a blaze of beautiful soft light from the incandescent globes. I called some friends to come into the room and see it. While they were making some experiments with the wires, the current was suddenly cut off. In an instant we were in utter darkness. But very soon, with a flash, the lamps were all in a blaze again. Perhaps these bright spiritual visions are hardly as quick as the electric current, but to the one whose heart is in perfect accord with Bible teachings, and to the one who is earnestly and honestly striving to follow Christ Jesus, texts of Scripture frequently light up with a wonderful new meaning, almost as vividly as did these beautiful electric lights. They fairly shine in their beauty and grandeur, and keep shining for evermore unless we darken them by deliberate acts of sin. For experiences like these, who would be guilty of such folly as to cloud and extinguish the light of God's love by things that can only sink us down in guilt and remorse.

As an illustration of the way these texts suddenly stand out with startling distinctness, I mention one that came into my mind a few days ago. I had been studying the lesson about restoring the daughter of Jairus. The servants came to him, saying, "Thy daughter is dead; trouble not the Master." Jesus, however, spake to him, saying, "Fear not; *believe only*." The two words, "*believe only*," came into my mind with sudden and startling distinctness. It is an exhortation to faith. Jesus told the father, that, even though his daughter was *dead*, he need not fear nor be troubled, providing he had *faith—believe only*. Have faith in Christ; trust the matter entirely to his hands, and nothing more is needed, and the promise comes down to us to-day—fear not, believe only. Another text has been much on my mind of late, and it is this: Most of us are constantly relapsing into a sort of infidelity, or want of faith. We can not believe, and steadily hold fast to the belief, that God has any great amount of care for us individually; or, in other words, we can not comprehend that the whole human family is dear to him. While this was in my mind, the thought came to me of what Jesus said, in speaking of the lilies of the field—"Ye are of more value than many sparrows;" and this I have been saying

over to myself again and again: God cares for the sparrows; and he cares for the lilies, and he cares for all this great wide universe. But there is nothing in it all so dear to the heart of the great Creator as mankind—even sinful beings, such as we are. In fact, we are not to be compared with any thing else in the whole range of creation. "Ye are of more value than many sparrows." Now, if we hold fast to this one thought, God's love, his regard and his kindness, and his many promises, this thought itself shall give us this well of water springing up into everlasting life.

In closing this number of *Our Homes* it occurs to me that there are quite a few among our readers who feel like saying that I had better look to home and attend to my own affairs, instead of directing other people what to do, especially in this matter of unfinished orders. Never before, since the Home of the Honey-bees was started, have we been so much behind in filling orders. John says that, on Saturday night, we were over *eight hundred* behind. We are running night and day. We have pressed new hands into the service until there are people who are working for me whom I do not know by sight nor by name. For once in my life I have had the privilege of saying "yes" to almost every one who applied for work. Our gardening operations are sadly behind, and I had hoped to get a man or boy whom I could keep on the grounds. Just as soon as we get one taught the ways of our work, a message is sent from the factory for "More help!" That you who are suffering for the want of goods may have a little more charity, I will try to explain a little the difficulty of refusing to receive more orders or of returning the money. These 800 letters containing orders are scattered through our offices, packing-rooms, machine-shop, tin-shop, saw-room, wax-room, type-room, yes, and even into the greenhouses; and when somebody complains that his order is not filled, it takes a smart clerk sometimes an hour or two to find the order at all. If the goods are already gone, the book-keepers can generally answer; but even their work is so much behind that we have of late been sending a postal-card notice of shipment, by the first train after the goods were loaded on the cars; then the book-keepers can take a little more time to make out the invoice, and to adjust the balances, etc. It is a harder matter to get new hands to take hold of the book-keeping than almost any thing else. Again, every mail brings us more or less additions to orders, change in orders, countermand in orders; and a great many ask us to put their goods in with those ordered by some neighbor. This overhauling orders in process of being filled is very laborious, and seriously interrupts the workmen among the machinery. We try to fill orders in rotation, but even this can not be done. Machinery breaks down, hands get sick, and a variety of things occur to stop a certain order; while one for something a little different, even though it came a little later, can go as well as not. All these workmen numbering somewhere between 150 and 200,

must be kept busy. While some orders are a month old, others, for a single lawn-mower, or even a honey-extractor or bee-hive, that happens to be ahead in stock, can go by next train; therefore it sometimes happens that a man may say with justice something like this: "You filled my neighbor's order within a week; yet mine has been with you for over a month." Others complain because we give them no notice of the delay, nor tell them what to depend on. Just now we hardly know what you *can* depend on; and to hunt up all the orders that are daily waiting for broken machinery to be repaired, or other similar accidents, would take more time than to fill the orders themselves. We stand ready to do *this*, however: To return your money promptly whenever you get tired of waiting. But with such a mass of business as we have now, every little while there is complaint that an order can not be *found*. One man asked to have his money returned or his goods sent; but it took some *three days of hard work* to find his order. When discovered we found it pinned fast to another man's order. He has asked to have his goods go along with those belonging to a neighbor; and to make sure they would go together, it was pinned fast to said neighbor's order. In the hunt, the two letters were supposed to be from the same man. The following letter shows the way in which my Christianity is frequently called in question:

Sir:—I sent you an order the 4th of April last, and received an answer that you had received it all right; since then I have not heard. Now, my Christian friend, is that the way you do business, or am I only an exception? It causes me a great deal of inconvenience, as Mr. Evans gave me an order which was put in with mine. He has bought 30 colonies, and is waiting for his smokers and wire, and nearly every day he comes and "dogs me" for his goods. He has finally concluded to write you and find out whether or not I have sent the order *at all*. Now, if you are so rushed as to make such unnecessary delay, I think you had better apply a little more genuine common sense, and real Christianity mixed, and employ a few honest and good men to attend to your customers' orders, for you know there is in every human being a desire to get what he has bought and paid for, within a reasonable time, say nothing about such delays as this. You undoubtedly remember a passage in the Bible that says, "Do unto others as you want them to do unto you." Now, when you order goods expecting them to be sent within a reasonable time, and you wait patiently over a month, and receive only a card, saying that the order and money had been received, and nothing further, I do not believe you would like to be treated in this way, would you? Now, if you have not sent the goods, please return the money, as we can not wait till next spring for the goods.

N. C. EVANS.

Mt. Horeb, Wis., May 9.

Friend E., I agree with you exactly. I should *not* like to be treated in that way. I am happy to tell you, however, that your goods were sent May 6, three days before you wrote the above letter. Your suggestion in regard to hiring good and honest men strikes one of our great troubles. I believe that *honest* men are as plentiful here as anywhere; but *competent* men—men who can, without experience, go into such a whirl-

pool of business as ours, and help things along, are not very plentiful anywhere. The objection to having a great stock of things *ahead* is this: Only two years ago we had so many things in our warehouse that were not used nor wanted, that we had to cut our working force down to eight hours a day, right in the month of May. Worse still, a good deal of the work made up ahead was superseded by something better, and had to be sold at a loss, or thrown away. We did not anticipate this present *great* rush this season. We are, however, now planning a larger warehouse than ever before, with a railroad track on each side of it. One train of cars fills it with material, and the other unloads it as it goes to our customers; and another railroad is now in process of construction, which passes through our grounds, giving us an outlet *east and west* as well as north and south, as heretofore. The burning of friend Lewis' plant has had something to do with this present rush. Another thing, friend E., you sent your order in April—the very month when the great rush of the season usually begins. You know we have cautioned you in our price list about waiting until the great hurry of the season came, before giving us your order. Your goods were not shipped for a month and two days after you ordered them; and if you will tell me what will make the matter satisfactory, I will try to adjust it in a Christianlike way; and I wish to say to all the other friends, tell me in a Christianlike way how much you have suffered by our apparent bad management, and I will try in a Christianlike way to make the matter satisfactory. But please do not do it until we get a little out of our present fearful crowd and jam. I do feel greatly and deeply thankful for your kind confidence and encouragement, of years past; and even though many of you *have been* badly used for a short time back, I venture to subscribe myself, notwithstanding,

Yours in brotherly love, A. I. ROOT.

EDITORIAL.

The steps of a good man are ordered of the Lord.—Ps. 37: 23.

EXHIBITS FOR THE WORLD'S FAIR.

DR. MASON sent us the following, which he desires us to add to his article on page 371. As the latter has been made up, ready for the press, we will add the same here:

I wish that all who are thinking of making an exhibit would let me know soon about how much space they will probably need; that is, about how many square feet of floor space. An average of over 250 feet each was occupied by the six principal exhibitors at the Ohio Centennial in 1888, where our friend A. I. Root's exhibit was crowded, although he was assigned a space of about 400 square feet, and some exhibitors with less than 70 feet made nice exhibits, and secured their share of premiums. Should the six or seven States nearest to Chicago make creditable exhibits, to say nothing of other States, there will be a grand display; but it is to be hoped that California, with her usual energy and vim, will not be one whit behind other States, and that Maine and sunny Florida, and that monster State, Texas, and all between, will do their share toward showing to the world a goodly sample of the sweetness within our borders; and we expect to be nobly backed by our Canadian friends, and we ought not to let them outdo us. I am corresponding with some of our leading exhibitors, to get their views for the benefit of all; and I have already written to some parties in the Old World, in the interest of the honey display; and when I speak of the honey display, I mean every thing connected with our industry.

A. B. MASON,
Auburndale, O., May 9.

DOUBLE TOP-BARS, ETC.

ON page 380, mention is made of a top-bar having openings made with a wabble-saw. In my hand is a similar top-bar from E. M. Tennent, Willett, N. Y., only, instead of having slots made in it horizontally, there are eight $\frac{1}{4}$ -inch holes bored. These holes will serve as a passageway for the bees, and, very likely, as a Hill device, or any thing of that sort. Ernest says that he has gathered from several letters, from those who have used double top-bars, that a narrower top-bar, if made double, will answer equally well in preventing burr-combs; that is, a top-bar $\frac{3}{8}$ inch square will answer all right, providing it is slotted so as to make it equivalent to a double top-bar. If not slotted, it must be fully an inch wide to give us good results. Are there others who have used double top-bars, who have noticed this? The idea seems to be this: The opening forming a bee-passage produces something of the conditions of a slatted honey-board.

SELLING SECRETS FOR A SUM OF MONEY.

OUR older readers remember how often I have denounced this custom, and how often I have insisted that nothing valuable ever comes in this way—that is, nothing that can not also be found in books and periodicals. Of late, several good friends of mine have called my attention to the wonderful discovery of Dr. A. Wilford Hall, editor of the *Microcosm*. Dr. Hall, so it is said, has discovered a method of treating disease without the use of medicines; and so wonderful were the results that it was claimed that one could live to be 100 years old or more, by this drugless remedy. The price is \$4.00, and the purchaser must sign a printed agreement not to divulge the secret of the treatment. I was quite willing to furnish the \$4.00, but very reluctant to sign such a pledge. I did so, however, and I am glad to be able to say that the treatment is, in my opinion (at least in my own case), valuable. Notwithstanding my pledge, however, I feel that I can, with a perfectly clear conscience, say that the treatment is not new, neither is there any discovery about it. It is simply a revival of one of the lines of water-cure treatment, known, nobody knows how long ago, and the whole thing is well known to our physicians, and fully described in our medical books. In fact, I can, if our readers wish, copy the whole thing from Dr. Kellogg's book, entitled "Rational Medicine," page 663. And Dr. Hall himself gives a lot of quotations in regard to the value of his discovery; and these quotations are copied from "*Chicago Medical Society Trans.*" What has already appeared in print, of course any publisher is at liberty to copy, giving proper credit. Now, although good may result from reviving this branch of water-cure treatment (and I feel sure it will result), I think that Dr. Hall should be published as a swindler for taking money from those who are out of health, for something that is already well known. The most lamentable feature in the case is that Dr. Hall claims to be a Christian, and would persuade suffering humanity that God has revealed this wonderful drugless treatment to him, that he may take \$4.00 apiece from his fellow-men, for a little pamphlet of only a few small pages. I am told that he has already received a good many thousand dollars in this way. I am sorry to say that many of the testimonials come from ministers of the gospel, and I do think these ministers ought to be ashamed of themselves.

CORKS FOR HONEY-BOTTLES.

WE extract the following from a private letter from Chas. F. Muth, on the subject as above:

All corks should be scalded with hot water before they are pressed into the necks of bottles. Put your corks into a bucket and pour hot water over them, when they will be as pliable as rubber.

CHAS. F. MUTH & SON.

Cincinnati, O., March 14, 1890.

LOOK OUT FOR THE BOGUS DICTIONARY.

DOUBTLESS some of you have seen flaming advertisements of a complete "Unabridged Dictionary" for three or four dollars. When the notice first came out we ordered a sample; and, without orders, one of the books was sent to our office C. O. D. Now, it is an unheard-of thing to bring a package into the office of the Home of the Honey-bees with "C. O. D." on it. One of the boys brought it in, and, without noticing the C. O. D., the book was opened and examined. As soon as I looked inside of it, it went right straight back to the express office, and the publishers tried to make us keep it, "because we undid the wrappings!" The whole thing is a swindle from beginning to end. I would add, that it is a reprint of an edition issued in 1847—43 years ago, but I doubt whether any thing was known as poor and shabby even at that time. There is not a single illustration in it, except in the back part; and in the body of the work there is not a reference to any of the illustrations in the back part. How much good do the illustrations do you in that shape? After some jangling about it, we were required to pay the express charges back on the miserable thing.

ARTIFICIAL COMB HONEY AND MANUFACTURED SCIENCE.

THIS is the title of an exceedingly well-written article in the *Popular Science Monthly* for May, by Allen Pringle, President of the Ontario Bee-Keepers' Association. The writer locates the source of the falsehood regarding manufactured comb honey to Prof. Wiley's article, which appeared in the *Popular Science Monthly* for June, 1881, and alludes to the fact of its having been copied in the *American Encyclopedia*, and in the Supplement to the *Encyclopedia Britannica*, besides being copied through the press generally. It seems that the editor of the *Popular Science Monthly* was not aware until recently that the mischief took root in his magazine. Just as soon, however, as he was informed of the fact, he asked Mr. Allen Pringle—a bee-keeper and a scholar—to reply to it, and he has done it in a masterly manner. We should be glad to publish the article entire; but as our space is crowded, we can not; but we can not forbear quoting from the last paragraph, which reads as below:

I take the liberty of here suggesting to publishers of encyclopedias and scientific works, the wisdom of first submitting doubtful points and dubious assertions, made by men outside their special departments, to practical men in such departments, whether the latter be learned or unlearned, for the knowledge of an unlearned man touching his own particular line of business (even the science of it) may exceed that of the scientist both in accuracy and extent. Such a course would often save the specialist from humiliation, and spare the public the infliction of some very queer science, which, not infrequently, fails to dovetail with every-day facts.

There is one sentence in the above to which we wish to call attention; namely, that the knowledge of an unlearned man in his own line of business may exceed that of the scientist, both in accuracy and extent. Why is it that encyclopedias will sometimes, instead of going to practical men for information, employ some big-named scientist of little

or no experimental or practical knowledge, to write up the facts? Allen Pringle is both learned and practical, and we hope, with Bro. Newman, that other periodicals will publish this masterly refutation as widely as they circulated the old Wiley fabrication.

FOUL BROOD.

BULLETIN 61, under date of April, 1890, of the Michigan Agricultural Experiment Station, treats on the subject as above, and it is signed by A. J. Cook. We have carefully looked it over, and consider it fully up to the times, and sound in its teachings. After treating of fungoid diseases in general, and dividing them into different groups as to form, such as micrococci, bacteria, spirillum, and bacillus (under which latter head comes foul brood), Prof. Cook goes on to describe foul brood in particular—its microscopic appearance, etc. His description of the symptoms of foul brood is good. Under "Remedies" he treats briefly of salicylic and carbolic acid. We are glad to see that he does not recommend them as a cure. Even our much-respected friend Chas. F. Muth does not recommend salicylic acid now, because he can not prevent reinfection. When we had foul brood, an old classmate of your humble servant, Ernest, while home on a vacation from Cornell University, was induced to make "pure cultures" of foul brood in test-tubes. In other words, he made a sort of beef gelatine, which, after being boiled, was stoppered in test-tubes with cotton batting. After heating the point of a needle, and letting it cool, he immersed it into diseased larvæ, and then plunged it into beef gelatine, which under the inoculation very soon became cloudy. These experiments were conducted with the greatest of care. "Now," said he, "if carbolic acid is a fungicide, it ought to arrest its progress." Into some of the inoculated cultures he introduced a small quantity of carbolic acid, and left it for a time. Instead of killing the bacilli as we expected, it had no effect upon it; for even after the addition of the acid other tubes could be inoculated. The phenol was administered in the proportions recommended by Frank Cheshire. That this was the real foul brood he had been treating, and not some other growth, was evidenced by examination with the microscope. If this experiment means any thing it means that carbolic acid has little if any effect as a fungicide. While it apparently kept down the disease in our apiary, I somewhat doubt whether it did any real good. I am glad to see that Prof. Cook recommends that sure and reliable method, transferring, as first announced by Mr. M. Quinby, and by him styled the "fasting" method, and, later, recommended by D. A. Jones. It never failed with us. Where hives are boiled for some minutes, the disease does not reappear. Some seconds is hardly safe, as the spores do not yield readily to a boiling temperature. Prof. Cook very much doubts whether the disease resides in the blood of the bees or queen, as suggested by Cheshire and argued by R. L. Raylor. We have repeatedly taken queens from diseased colonies, and dropped them into perfectly healthy ones, and no trouble followed. But that it does reside in the honey, and that it can be carried by robbers to all parts of the apiary, is beyond any question or doubt with us. Scores of instances have proved this. We are glad to recommend this bulletin to any who may have had foul brood, or have any doubt as to whether they have it or not.

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 6 lines, and you must say you want your ad in this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. This department is intended only for bona-fide exchanges. Exchanges for cash or for price lists, or notices offering articles for sale can not be inserted under this head. For such our regular rates of 20 cts. a line will be charged, and they will be put with the regular advertisements.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I have on hand about 20 fine hybrid queens which I will sell at 30c each, or 4 for \$1.00. Selected, 50c. A. A. WEAVER, Warrensburg, Johnson Co., Mo.

Two black and 6 fine prolific hybrid queens for sale. Any one sending 25c each, and ready-provisioned cage, can have them. T. K. MASSIE, Concord Church, Mercer Co., W. Va.

100 black and hybrid queens to one address for \$25.00. 11-12d ANTHONY OPP, Helena, Ark.

I have a few hybrid queens with some connection mixture, 50c each. W. H. FOSS, Topeka, Kan.

Care of A. T. & S. F. Store house.

A few hybrid Italian queens for sale at 30c each. LLOYD SECHRIST, Pleasant Home, O.

I still have 6 black queens for sale at 25c each. W. P. W. DUKE, Nettleborough, Ala.

Twenty pure black queens for sale at 30c each, or 4 for \$1.00. Ready by June 5. THOMAS NICHOLS, Dixie, Nicholas Co., W. Va.

I have about 50 hybrid queens that I will mail to those who speak quick for 25c each. I wish to re-queen my apiary, and dislike to pinch the heads of so many queens. T. P. GILHAM, Lincoln, Tenn.

Fifty hybrid queens for sale, 40c each; 3 for \$1.00. J. M. KINZIE, Rochester, Mich.

Black and hybrid queens at 35c each. DAVID DANIEL, West Millville, Clarion Co., Pa.

Mismatched Italian queens at 35c each; 3 for \$1.00. E. S. VICKERY, Hartwell, Hart Co., Ga.

LET US HAVE FAIR PLAY,

is all we ask. We know you will like our Carniolan bees, because we breed from **Pure Imported Stock**. Queens, \$1.00 in June. Give them a **Fair Trial**. Send for printed matter free. Safe arrival. Address **E. L. PRATT**, 8 11db **Pratt Bee-Farm, Marlboro, Mass.**

☞ In responding to this advertisement mention GLEANINGS.

LOOK! Italian Queens, 10 to 75c.

Tested, 75c; untested, 45c; hybrids, 10c. Safely delivered by F. C. MORROW, Wallaceburg, Ark. Please mention this paper.

WHAT TO DO,

—AND—

How to Be Happy While Doing It.

The above book, by A. I. Root, is a compilation of papers published in GLEANINGS in 1886, '7, and '8. It is intended to solve the problem of finding occupation for those scattered over our land, out of employment. The suggestions are principally about finding employment around your own homes. The book is mainly upon market-gardening, fruit culture, poultry-raising, etc. I think the book will be well worth the price, not only to those out of employment, but to any one who loves home and rural industries. Price in paper covers, 50 cts.; cloth, 75 cts. If wanted by mail, add 8 and 10c respectively.

A. I. ROOT, Medina, Ohio.

Saws that Never Need Filing.

Ever since we first gave notice of the Star saws, some years ago, the blades of which were sold so cheap that a new one could be put in cheaper than to have a saw filed, there has been an immense trade in them. The Millers Falls Co. have recently got out the saw shown in the cut below, that takes

a 14 inch blade, and yet the price is only 50 cts.—saw, blade, and all. Extra blades cost a dollar a dozen; therefore, when your saw needs sharpening it costs less than 10 cts. to have a bright new blade, ready for business. And this is not all. These Star saw-blades, by some special process, are given a higher temper than anything else in the saw line. You can saw a board or a bone, saw off a gas-pipe or a gun-barrel, and all with the same saw. The first one I ever saw I carried down into our machine shop, gave it to our machinist, and told him to see what it was worth. After a few minutes' trial he asked the price and handed out the money, without a word. The truth is, he had never seen any thing like it before, for sawing iron and steel. The one we picture is made a specialty, to be hung up in the kitchen; and I rather think, my friend, you can not make your wife a better present than to get her one of these saws, to hang up in her kitchen. If you behave yourself, maybe she will lend it to you occasionally; but, be sure to bring it back when you are done with it. If you don't, there may be a family jar. If wanted by mail, the price will be 20c extra. Postage on blades, 10c per doz. Star butcher saws have been reduced in price. See page 42 of our latest price list.

A. I. ROOT, Medina, Ohio.

PASTEBOARD BOXES,

Or Cartons, for One-Pound Sections.

Bee-keepers are realizing more and more the value of these cartons for putting their comb honey in marketable shape. Other articles of home consumption are put up in a neat attractive way, and in shape to be handed to the customer, and carried safely without wrapping. Why not sections of comb honey, especially when the cost of the boxes is so low?

TABLE OF PRICES OF 1-LB. SECTION CARTONS.

Name or designation.	Price of 1	25	100	500	1000
1-lb. carton, plain.....	2	.30	.60	2.75	5.00
1-lb. carton, printed one side, name and address.....			.90	3.50	6.00
1-lb. carton, printed on both sides, name and address.....			1.00	3.75	6.50
1-lb. carton, with lithograph label, one side.....	3	.30	1.00	4.50	8.50
1-lb. carton, with lithograph label on both sides.....	3	.40	1.30	6.25	12.00
1-lb. carton, with lithograph label one side, name printed.....			1.30	5.25	9.50
1-lb. carton, with lithograph label, printed with name on both sides.....			1.70	7.25	13.50
Lithograph labels, 2 designs, for 1-lb. cartons.....			.35	1.60	3.00

If sent by mail, postage will be 2 cts. each; or in lots of 25 or more, 1 cent each. All the above have tape handles. Price, without tape handles, 5c per 100, or 75c per 1000 less. The quality of the boxes is fair, being made of strawboard, plated outside. If more than 1000 are wanted, write for prices.

A. I. ROOT, MEDINA, O.

HONEY COLUMN.

CITY MARKETS.

KANSAS CITY.—*Honey*.—The demand for comb continues good, 1-lb. white selling at 14 cts.; 1-lb. dark, selling at 10@12; extracted white, 5@7; extracted amber, 5@6. We are in good shape for a new crop, which we look for next month.

May 20. CLEMONS, CLOON & CO.,
Cor. Fourth and Walnut Sts., Kansas City, Mo.

DETROIT.—*Honey*.—There is very little good honey in the market, and by the time new comes in the market will be nearly bare; comb is still quoted at 11@13 cts; extracted, 7@8. *Beeswax* in demand at 26@28.

May 20. M. H. HUNT,
Bell Branch, Mich.

NEW YORK.—*Honey*.—Honey market quiet. Extracted California, 7½@8; Cuban strained, 79 cts. per gallon. *Beeswax*, supplies nearly exhausted; demand good. We quote 29@30 per lb.

F. G. STROHMEYER & CO.,
New York.

BOSTON.—*Honey*.—No change in honey market here since last writing.

May 19. BLAKE & RIPLEY,
57 Chatham St., Boston, Mass.

SAN FRANCISCO.—*Honey*.—New honey is already coming in, and we quote 5½@6. Comb honey, 9@12. *Beeswax* scarce, 23@24.

SCHACHT, LEMCKE & STEINER.
May 11. 16 & 18 Drum St., San Francisco, Cal.

COLUMBUS.—*Honey*.—As the season for old honey closes, the demand decreases. Sales slow at 14 cts. for choice stock. No sale whatever for off grades.

May 20. EARLE CLICKENGER, Columbus, O.

ST. LOUIS.—*Honey*.—We quote market quiet, as follows: Choice white clover, comb, 12@12½; dark and inferior, 8½@9½; extracted and strained in cans, 6½@8½; barrels, 5@5½. Prime *beeswax*, 27.

D. G. TUTT GROCER CO.,
May 19. St. Louis, Mo.

ALBANY.—*Honey*.—Owing to the continued cool weather the demand for honey during the past week has been very good, at quotations which remain unchanged.

C. MCCULLOCH & CO.,
May 22. 339 Broadway, Albany, N. Y.

KIND WORDS FROM OUR CUSTOMERS.

MARCH'S CAULIFLOWER SEED.

I sowed cauliflower seed on the same day, and in the same bed, from three seed firms, and I tried to sow them just the same; but when they came up, March's seed stood three to one over the other sorts.

GEO. M. KELLOGG.
Pleasant Hill, Mo., Apr. 14.

BENTON MAILING-CAGE.

Your imported queen, mailed to me on the 6th, arrived in fine condition on the 10th. I safely introduced her according to directions accompanying her, and upon examination on the 12th I found one frame nearly filled with eggs. I must say your caging and mailing methods are unsurpassed.

Lavaca, Ark., May 14. W. H. LAWS.

ITALIAN * QUEENS.

From June 10th to Oct. 1st.

Why you should purchase of Wood:
He has had many years' experience.
His queen-cells are built in full colonies.
He uses no lamp-nursery.
He is located where there are no black bees, and where full brood never was known. Fully 95 per cent of his queens prove purely mated.
He fills orders promptly.
He warrants every queen equal to those of any first-class breeder in America.
Price 75 cts. each; \$8.00 for 12.

Address **JAMES WOOD,**
11tfdb **North Prescott, Mass.**

Bee-Keeping for Profit

IS THE TITLE OF

Dr. Tinker's New Hand - Book.

It gives his **New System** of the management of bees complete, telling how to get the largest yields of comb and extracted honey, and make the industry of bee-keeping a profitable one. The claim is made that our old methods and appliances are of such a nature that it does not pay even the expert bee-keeper to keep bees except in very favorable localities. The New Book tells why these failures occur and how to prevent them, giving the general principles essential to a profitable system. The work should be in the hands of every progressive apiarist. It is well illustrated, and will be sent to any address postpaid for 25 cts. Please remit by postal note. Address

DR. G. L. TINKER, New Philadelphia, Ohio.

SPECIAL NOTICES.

HENDERSON'S BUSH LIMA BEAN.

As the bush lima bean does not seem to go off this spring as we expected it, we reduce the price one-fourth after June 1. After June 15, if we have much stock on hand the price will be one-half the regular price of \$1.00 per quart.

THE PLANT-TRADE, JUNE 1.

We have been short on almost every thing this spring, except celery. We have now in stock, and have had all along, large transplanted celery-plants, White Plume and Golden Self-blanching, and these are considered best for early. We have also at present all kinds of cabbage and all kinds of tomatoes, advertised in our seed catalogue. We are short on cauliflower, in spite of all the efforts we have made to set them growing. We are also short on pepper-plants.

JAPANESE BUCKWHEAT.

It will soon be time to sow buckwheat, and, of course, no one will think of sowing any thing else, after the record the Japanese has made. It has, in fact, brought the price of buckwheat down to a point seldom if ever known before. In our locality, from the 20th of June to the 1st of July is the usual time for sowing it. It will, however, usually give a crop almost any time during the month of July. As much as 50 bushels per acre have been secured, and it rarely sells for less than 50 cts. per bushel. It is harvested so soon after sowing the seed that you get quick returns. We have a large stock of seed ready to ship by the first train, at following prices. Per lb., 5 cts.; 40 cts. per peck; 75 cts. per ½ bushel, or \$1.00 per bushel; \$2.50 for 2 bushels; in lots of 10 bushels or more, \$1.10 per bushel, bag included in every case, without charge. Put in two or three pecks per acre, according to the condition of the soil. Now, please bear in mind that there is always trouble in shipping small lots of buckwheat, either by freight or express, because the charges are more than the value of the seed. A few days ago a friend wanted a peck of buckwheat sent away down to Texas. After the figuring up, we found the cheapest way to get it to him was to send it by mail, at an expense of over \$1.00 for postage, while the buckwheat and bag cost him only 40 cts. To prevent disappointment, ask what the probable expense will be, before you make your order.

FILLING ORDERS AT THE HOME OF THE HONEY-BEES.

At this date, May 28, we are still running night and day, and every thing is booming in every de-

partment. Hold on! There is one room in our establishment that has been for one or two days deserted and dull. When orders poured in until we were a full thousand behind, we decided to stop sending out price lists except to applicants; therefore the big printing press was shut down, and the pressman went to helping the boys in the next room to fill orders. For a time it seemed that nothing could keep pace with the flood of orders. We were 500 orders behind, then 700; and when it was more than 1000, things began to look desperate. By redoubling our efforts, however, and permitting those who could stand it to put in 14 or 15 hours a day, in one week we got the 1000 back to 700 again, and now we are reducing it still more; but many of our customers have lost all patience, and are demanding their money back.

Now, do not imagine, dear friends, that we are not able to fill orders for any thing promptly. One poor friend asked if we could not possibly send him a sheet of perforated zinc, letting the rest of his order remain. Why, we could send you any amount of zinc by return train, and, in fact, almost any thing else, except bee-hives and sections. All goods ordered by express or mail, have, with hardly an exception, gone within 24 hours. The great unfulfilled want is for sections, and the rainy weather has made it impossible to dry the basswood, and this has been one great obstacle in the way. We are now having beautiful warm sunshiny days, and the basswood is fast getting fit to work.

Of course, our dry-kiln is running night and day, with the rest of our machinery; but we find even that inadequate, unless backed up by bright sunshiny weather. As heretofore, many of our troubles and delays have been caused by hasty writing and imperfect addresses. We had a list of seven men who had sent us money, and yet their orders could not be found. Four of the seven have been straightened out and their things sent. The trouble was, in their letters of inquiry they wrote their names so badly that nobody could decipher them accurately. Oh, if you only *would* have your correct name and address printed on your stationery, all of you, what a great help it would be!

Wire Cloth.

For door and window screens, tacking over hives and nuclei for shipping, making bee and queen cages, and a variety of purposes. We have the following list of green and black wire cloth which is not exactly first class, but is practically as good for the purposes mentioned, and at prices MUCH BELOW the ordinary price. You can no doubt select from this list a piece to suit your needs. Price in full pieces, 1½ cts. per square foot. When we have to cut it, 2 cts. In case the piece you order may have been taken by some one else before your order comes, please say whether we shall send the nearest in size, or cut one the size ordered at 2 cts. per ft., or give a second or third choice.

No. of Rolls, and Color.	Width, In's.	Length, Ft.	Sq. Feet.	Price of a Full Roll.	Pieces less than 100 ft. long. These figures are the number of square feet in each piece. Multiply by 1½ cents for the price of piece.

A SOLAR WAX-EXTRACTOR FOR LIQUEFYING CANDIED HONEY.

RIPENING EXTRACTED HONEY BY MEANS OF A
SOLAR WAX-EXTRACTOR.

THE illustration in GLEANINGS of April 15 has brought some inquiries in regard to the mammoth solar wax extractor shown there. A few explanations will probably make it better understood.

In size it is 5 ft. 3 in. x 2 ft. 9 in., and 8 in. deep. A chamber at the lower end, where a pan catches the melted wax, makes the entire length about 6 ft. It is made of $\frac{3}{4}$ -inch pine lumber. The bottom is of narrow matched stuff, to make it tight. It is thoroughly painted a dark color, inside and out, and covered with glass. On the upper part I have used window-sash, which is removable. The lower part, or chamber, has glass, also removable, for the convenience of getting at the wax-dish. It is mounted on wheels in front, for convenience in moving, with legs at the back end, giving it an incline of about 45 degrees.

This extractor works very nicely, as illustrated and described. But I will note some of the improvements suggested by its use. The window-sash are a little imperfect, as the bars of wood between the glass obstruct the sun so that the wax cools under them in their shadow. It would be better to have the glass unobstructed by bars, or at least have them as small as possible. Two large glasses, I think, in place of the sash, would be a decided improvement.

Reflectors would give some additional heat, and make the machine much more complete. I designed these to hinge upon each side, and to answer, when closed, as a cover to protect the glass and keep out the dust and rain when not in use, having them wide enough to shut together in roof

shape, and lined on the inside with tins to reflect the sun. These can be fastened open at any angle desired, when used as reflectors.

A correspondent asks, "What prevents the combs from sliding down when they melt?" They will not slide down; but the wax will melt and run out, and leave the old comb and residue, which can be removed at your leisure. It gets out the wax in the best condition, and with the least labor of any method I have ever tried, and I have tried a good many ways; and I am not done yet. I have something else to say about the solar extractor. We all know how much trouble it is to liquefy granulated honey. But some one says, "Don't do it." But we have to do it sometimes; and when we have occasion to do a job of this kind, just place it in the solar extractor, if in cans or pails, or any convenient packages to go inside; or if in bulk, have a large pan on purpose. It is much better than any method where artificial heat is used. It can also be used to evaporate extracted honey by having a wire-cloth screen at the upper end, to be opened for ventilation. In order to make it convenient for melting or evaporating honey, I would suggest, instead of fixed legs at the back end, a standard with holes through it, and a pin with which to fasten the machine at any desired inclination. It could then be let down to a horizontal position for this purpose. Just put the honey in and go about your business. It won't burn nor spoil, but the work will be done in the cheapest and very best possible manner.

The greatest drawback I have found in the use of a machine of this kind is a lack of sunshine. You will be as astonished as I was when you come to use one, at the very few days in the whole season in which we have clear, unobstructed sunshine—a necessary condition for the complete success of

a solar extractor. And isn't it also possible that this lack of sunshine for the last few years plays an important part in the failure of the honey crop? Yet I regard it as a valuable acquisition to the apiary, in any locality; but in the South, in the land of perpetual sunshine, I should place it beside the extractor and foundation-mill for usefulness in the apiary—an indispensable labor-saving machine.

Now I am done. If you are ingenious I think you will be able to build the extractor, as described and illustrated.

H. R. BOARDMAN.

East Townsend, O., May 8.

Friend B., I congratulate you on your discovery that the solar wax-extractor is the best thing for liquefying granulated honey. May be the idea has come up before; but if so, I had forgotten it. But, are you sure that the heat of the sun will never injure the honey? If so, it is a big item in its favor. In our greenhouse experiments we have had ample opportunity to see how many sunny days there are. But we have had an unusual amount of cloudy weather for three seasons past. Wait until we have a drouth; then you can render wax, and liquefy the honey to good advantage. The glass should most surely be put in greenhouse fashion—that is, so as to let the water run down unobstructedly, and large pieces of glass are certainly an advantage over the small ones. Would not a large screw, such as is used in the bottom of a music-stool, be the best thing to get the proper inclination? or, better still, have two such screws, one on each back corner. Now have the front raised on a pivot, and you can have any angle you choose. I suppose one reason why solar wax-extractors are so much more common in California is because of the perpetual sunshine there. In fact, I am told that they have at least some sunshine every day in the year, and a good deal of the time whole months without an obstructing cloud. For a honey-evaporator you must have ventilation both at top and bottom, to get the best advantage. We tried drying green corn in our greenhouse, but it would not dry a bit. It only turned sour unless ventilation was given sufficient to let a light stream of hot air pass over and through the corn.

EXHIBITIONS AT FAIRS.

PROF. COOK SUGGESTS SOMETHING IMPORTANT.

Dear Mr. Root:—You will remember that, at the Michigan State Bee-Keepers' meeting held last winter at Lansing, the question of exhibits at fairs was fully discussed. You will remember my surprise when some persons present said it was not necessary that the exhibitor should have produced the honey which he exhibited; that he might get it anywhere. At our Michigan Central Bee-Keepers' meeting the other day, the question came up again. It was the unanimous opinion of those present that all honey should be produced by the exhibitor, and all but one person thought it should be the product of the year in which the exhibition was made. I was appointed a committee to urge upon the authorities that this opinion should be embodied in a rule governing all future exhibitions at our State Fair. I have consulted the authorities, and find

that we are too late for this year. The premium list is printed, and can not now be changed. I should like your opinion on this subject, and also the opinion of others. It seems to me that equity, and the entire aim of such exhibitions, demand that no person exhibit other than his own product. Fairs are not to stimulate hunting about to find beautiful honey, but to incite to its production. If this rule is adopted, then the neat, skillful apiarist, not the traveling collectors, will get the premiums. Ought he not to have them?

The other question, production during the year of the exhibition, might be opposed, as, during very poor years, it might be difficult to make a fine exhibit, and if a man made a fine design of wax he might desire to use it successive seasons. Yet even here it is the only fair way. Then all are on an equal footing, which would not be true if honey produced in previous years could be exhibited. Wax for ornament could be brought, no matter when fashioned; while that for premiums should have been produced the season of the exhibit.

Thus it seems to me that such a rule should be made to govern in all our fairs. The exhibit should be the product of the exhibitor, and should have been produced the year of the exhibition. Is this not so? Let others speak.

ADULTERATED HONEY.

Mr. R. A. Hardy, of Lampasas, Texas, sends me some extracted (?) honey which he says is sold in his vicinity by a bee-keeper in an adjoining town. He thinks some artificial feed was given to the bees, which they stored in the combs. He desires me to state through GLEANINGS what I think it is, and how prepared.

I should say that this is genuine honey—at least I see no reason to think otherwise. I do not know the kind. It seems rank, both in taste and odor, like some of our autumn honey at the North. There seems to be much wax in it, as though capings were left in. In a mouthful of the honey one gets quite a mass of the wax. I should say that this was a very questionable way to prepare extracted honey for market, and I should not suppose it could compete with honey that is free from wax, etc. Bee-keepers should be careful to exclude all substances from extracted honey, else buyers will suspect adulteration.

FLORIDA BEETLES.

Dr. J. H. Hunt, Tallahassee, Florida, sends me several beetles in a strong box, with cotton, by mail. They came in nice shape, and all alive. He says he finds them quite abundant about his hives. He reports that they seem eager to get into the hives, but for what purpose he can not tell. He can discover that they do no benefit or injury. He can almost always find them on the enamel cloth above the bees, and very often sees them going into the entrance of the hives. "Please give name and your opinion of their object in visiting the hives. I shall be glad to send you more if you wish them for experiment for your cabinet, or for the college."

This beetle is *Euphoria sepulchralis*, Fab. It is half an inch long, and is dark brown, with dashes of white on its back. I have it from Maryland, District of Columbia, Georgia, Florida, and Texas. Thus we see that it is widely distributed in the South. We have two of the same genus north, *E. inda* and *E. melancholica*. The latter looks very much like this one, except that it is a little larger. Ours as grubs live in the earth, and feed on roots of

vegetables; and as mature beetles, both feed on ripe fruit like apples, peaches, and on soft green corn. This gives a pretty decided hint as to the attraction which the bee-hive has for this Southern species. I think that, without doubt, they have sampled Dr. Hunt's honey, and, finding it quite to their taste, they help themselves as inclination prompts. I hope Dr. Hunt and others will examine closely and see if this is not so. If it is a fruitless search in the hives, try some in a box with a glass cover, in which a small piece of honey in comb is placed, or some candied honey, and see if they do not prove my conjecture true. Our *E. inda* flies much like a bumble-bee, and is easily mistaken, when on the wing, for one. I am very glad to receive insects from Dr. H. and others.

A. J. COOK.

Agricultural College, Mich., May 10.

Friend Cook, I am very glad to have you take this matter up. At different conventions it has been urged that the course you propose would certainly result in tempting people to tell lies. Now, there may be something in that; but, notwithstanding, I would have it exactly as you say. It has often been urged that our rules in regard to the use of tobacco in our establishment and on our grounds would result in inducing boys to become hypocrites. Perhaps it does now and then; but I think the good the rules do, far overbalances this occasional evil. I feel satisfied that the original purpose of county fairs was to encourage improved farming, and improvements in all rural industries. If the exhibitor does not bring the product of his own handiwork, what does it amount to? In our neighborhood it is quite fashionable for boys to borrow choice specimens of poultry from those who have not time to make the exhibits and carry off the premiums. It is surely all wrong. Let the judges make careful inquiry, and ascertain whether the exhibitors are residents of the county, and whether they are men of character. A little inquiry will easily determine. Then this fashion of going about from fair to fair, and getting a premium on the same article, will be done away with. Of course, I allude to rural products. Those who wish to advertise goods they have for sale, are, of course, privileged to get said goods in any way they choose; but in competing for premiums on the products of the soil, it seems to me none but the producer should have a premium.

Your experience is like my own in regard to samples of honey sent in, purporting to be spurious. I think that, in every case, I have pronounced them genuine. Those who are looking out for fraud of this kind, fail to consider that bees often gather natural honey of a very poor quality.

BEES IN THE AXTELL APIARY.

FEEDING SORGHUM IN OPEN-AIR FEEDERS.

This afternoon I was out and worked six colonies of bees through, clipping the queens' wings and getting them in a condition that will need no more work until we go through to build up into strong colonies just before the honey harvest. It is almost too early to clip queens now; but I am weak, and can't work long at a time, and I want to com-

mence now, so as to do all that I can of it myself, for several reasons. One is, I want the outdoor exercise and bee-stings, to build me up; and another reason, if I do it it will leave that much more time for Mr. Axtell to do something else that I can not do. Again, I think I can do it just a little more carefully than any one else. I believe many colonies are injured by careless handling. Perhaps I should not call it carelessness, but the lack of ability to do every little thing that needs to be done with that exactness that contributes to the welfare of the colony. And still another reason for wanting to work the hives myself is to see just how much stores they have, and how much and often we need to feed.

Those hives we put out in the middle of February because we could not keep so many in the cellar cool enough, are, some of them, nearly out of honey, but they have large quantities of brood and plenty of bees; while the remainder, carried out the latter part of March, have honey to last a month longer, and have less brood and fewer bees.

FEEDING BLACK SORGHUM MOLASSES.

We are feeding very black sorghum molasses that is two or three years old, and soured a little, and honey, half and half, melted together. Yesterday we fed a pail of each, and four of water stirred together—six pailfuls to 136 colonies. Before night they had taken it all up. It should be just thin enough so that the bees will fill themselves and fly home without crawling off upon the grass to clean themselves off first, which they will do if too thick. We shall gradually take away the honey, though I think they will not take such black molasses without some honey or sugar. The better the molasses, the less honey or sugar is needed to get them to take it. If they won't take it at first, or if we don't get in enough honey, we dilute some honey and sprinkle around over the feeders to start them. Our feeders are the large water-tight boxes we had to drain our extracted combs, in with thin boards nailed together just two bee-spaces apart, as floats in the boxes.

I examined each colony carefully, as we never fed such poor molasses before. It has been about three weeks since we began to feed. We fed once or twice a week. The bees look very thrifty and energetic, and the hives have all the brood they can care for, and are very full of bees for this time of year, with some drone brood. They have a little of their own honey left in the hives yet, and are gathering a little honey and pollen from the box-elders, and perhaps from some other source. I would not feed molasses, especially soured molasses, before bees fly in the spring; but as soon as they do fly freely, after the middle of April I doubt whether any sweet that we can get them to take, that is not really poisonous, would hurt them. Of course, it should not be fed while the supers are on, so that any of it could be stored in the sections, nor so much fed to the bees that they store and seal it up in their combs, so that it would be left over for winter stores.

From present appearance there will be but very few weak colonies by swarming time. I think we have never had bees to winter better; no colonies that I yet know of have died or dwindled that had a good queen in the fall.

White clover has wintered well, and is coming up in abundance everywhere. If we get sufficient rain we may hope for a good crop; but a good crop

means low prices, and each one should try to develop his own home market as much as possible. Try to trade it for every thing you buy, also exchange it for labor done. Try to trade it to every merchant in town nearest by; as often some one merchant will sell more than all the rest.

We had a large lot of cut-out honey, much more last fall than we ever had before, which we cut out and put into pans, which has sold more readily than in boxes. One groceryman wanted a panful every few days. He did not want more than two pans at a time, as it looked mussy from standing. I think the reason it went faster than in sections was, it was kept standing open, where a crate of sections has a lid on.

MRS. L. C. AXTELL.

Roseville, Ill., Apr. 24.

Mrs. A., I am very glad of your brief testimonial in favor of bee-stings. If it is really true that getting stung does good, instead of harm, it is a strong argument in favor of bee-keeping.—I have fed poor molasses in just the way you mention, and I am well satisfied that you can feed with safety any thing the bees will take or can, be induced to take, if it is done when they fly freely, and the weather is warm; and I am sure that great quantities of brood can in this way, be secured from very cheap feed, when it is desirable.—Your suggestion in regard to getting rid of the honey around home, instead of crowding the commission houses, is an excellent one.—I am very glad to know that you have succeeded as we have, in disposing of cut-out honey in pans.

NON-SWARMING QUEENS.

DOOLITTLE FEELS HOPEFUL IN REGARD TO THE MATTER.

On page 215 of the current volume of GLEANINGS I find an article from Mr. S. A. Shuck, in which he enters a protest against the teachings of Messrs. Alley, Doolittle, and others, who are giving advice to those who wish to increase their bees on the swarming plan, or by means which allow of increase being made without confining the bee-keeper to the apiary from 9 A. M. to 4 P. M. each day during the swarming season, he claiming that "the whole arrangement was unsatisfactory, and entirely too expensive." He then goes on to state that hundreds of bee-keepers don't want swarms, which I have not the least doubt is the case, yet it is equally certain that *hundreds* of bee-keepers do want swarms; and it was to these I was writing, and not to those who, like Mr. Shuck, do *not* want them. What Mr. Alley's object was in writing, I do not know; he can answer for himself. The point I wish to make right here is, that, in thinking of what should be written or what should not be written, we must take in the great multitude of bee-keepers as a whole, and not narrow ourselves down to just what *we* want, but go out in our thoughts, asking the question, "What will be the greatest good to the greatest number?" Failing to do this, we are not complying with the golden rule, nor using that broad charity for others which it is our privilege to use at all times, would we be making the world better for our having lived in it. I think that, in the past, I have given more matter on "how to prevent increase," and save to others the providing to themselves with those "hundreds of

dollars' worth of empty hives," than I have on the different modes of increase; for, on the whole, I am in favor of running an apiary on the plan of as little increase as possible; yet while I now so feel, I have not forgotten the time when I was so anxious for natural increase that I lay awake nights planning how it might be obtained.

Mr. Shuck next strikes some hard blows at queen-breeders for "diffusing the swarming mania" throughout the country. While I very much doubt there being any ground, only a mistaken one, for his wholesale slaughter of queen-breeders, yet this brings me to the main point I wish to make in this article; which is, Is it possible to breed out of our bees the disposition to swarm? I have always said that it is not, nor do I now believe it entirely possible; yet some things have come under my observation of late, that have modified my opinion to a considerable extent. I had thought not to say any thing in the matter till I knew more about it; but I have concluded that it will be better to speak of it now, so that others may try with me to see if perfection can not be reached sooner; for, "In a multitude of counselors there is safety." All who have read my book on queen-rearing will remember that, in 1884, I adopted a different plan of rearing queens than that usually adopted by those sending queens out for market. All who have had experience in the matter, also know that the best of queens are reared in case of two queens in a hive, or, in other words, where a young queen is reared and fertilized from the same hive which has an old and laying queen in it at the time when this young one is reared. This is a fact which none will dispute; but the point to be arrived at is, Are queens thus reared less likely to swarm than are those reared under the swarming impulse? The method I adopted for rearing queens in 1884 was nearly the same as that used by the bees where two laying queens are tolerated in a hive at the same time, as the queens are reared above a queen-excluding honey-board when the old queen is doing full duty below, the colony not having the least disposition to swarm while the queens are being reared; yet the most of my queens are reared during the last half of July and the month of August, at which time very few if any swarms issue with me.

With the year 1887 I began to notice that I was not having nearly as many swarms as usual; while during 1888, only about half of my old colonies showed any desire to swarm. During 1889, less than half of the old colonies swarmed, while only one showed a desire to cast an after-swarm, the queen-cells in all others being cut as soon as the first young queen hatched, without any attention to them on my part. All the older readers of GLEANINGS will remember how that, during the seventies, I had excessive swarming, one season having above 350 swarms from less than 70 colonies in the spring. Swarm they would in spite of all I could do, so that it was nothing unusual for me to have from five to ten swarms in the air at once, while in one case I had fourteen all clustered together in a hedge fence. As I go back to those days in memory, it certainly does seem that I have made progress along the non-swarming line, and it certainly does look as if the mode of rearing the queens may have had something to do with it. To be sure, the seasons of 1888-'9 were not good ones for honey, which may have had something to do with the matter; yet the season when the greatest

number of swarms issued was not a good one by any means, only about half a crop of honey being obtained. I shall look more closely into the matter the coming season, and I wish all who raise queens entirely above a queen-excluding honey-board would test the thing also, and so be helping to solve the problem, that a definite conclusion may be reached as speedily as possible. Why I say "entirely," as above, is, that some advise having the cells started by colonies having the swarming impulse, and, after they are started, place them above a queen-excluder for completion. Of course, this would not be entirely along the line we are working on, consequently would not be likely to be as perfect as to results.

I see on page 318 that the editor interprets that portion of my article in the May 1st No. of GLEANINGS, where I speak of policy, as applying or intended to apply to others. I had no such thoughts; and if it does look a little different, let the reader be assured that Doolittle was the only one it was meant for.

G. M. DOOLITTLE.

Borodino, N. Y.

Friend D., I am inclined to agree with you thus far. If we save our queens, and use them for breeders, that come from colonies that persistently swarm excessively, our chances are greatly in favor of getting a strain of bees given to much swarming; and, of course, the reverse would follow. But it seems to me it can hardly be possible that we shall see a perceptible difference in so short a time as you mention. If, however, you take pains to select queens from colonies that do not swarm, I think quite likely you would see a remedy to the evil of excessive swarming, even in three or four years. Almost every apiary furnishes more or less colonies that give good yields of honey year after year, without any swarming. Let us try getting our queens from such colonies.

USING ESCAPE TENTS.

WILL THE REESE BEE-ESCAPE TAKE THEIR PLACE?

ON page 201 Mrs. Axtell speaks of the bees being so slow in getting out of the little mosquito-bar tents that the sections were spotted. I am not troubled in that way, and I think she is right in blaming the young bees. I smoke the bees pretty well before taking off the super. This does not drive them all out by any means, but I think the young bees are pretty prompt to go down when exposed to the smoke and the light. If the super is taken off without giving the bees any time to go down, there may be in it young bees which have never flown, and such bees would be a long time about leaving the only home they know of. The Reese bee-escape, in some one of its forms, has the advantage that no bees need be driven out before applying the escape; and for home use I think it is ahead. For out-apiaries the little tents are ahead, for the bees can be got out of the supers in less time.

CAGING QUEENS.

The article of Mr. Gill, on page 203, and the comments thereon, prompt me to advise against trying the plan of caging on too large a scale, till you find whether it is the best thing in your case. I am obliged to confess that, with me, it has not as yet worked out as well in practice as in theory. I

think I can prove very conclusively by argument that there is a loss in raising bees at certain times; and yet, somehow, when the thing is put into actual practice the proof is not so clear. Indeed, to make a fuller confession, I believe if I had never tried to prevent swarming I should be better off to-day. Still, I am not ready to give up trying. But I am afraid that in spite of all my theories, the colonies wherein are left, all the time, laying queens, will persist in doing better work than those which are prevented from raising useless consumers. It may be, that I shall never get a satisfactory answer; but to me this question is a very interesting one: How can the desire to swarm be prevented without interfering with the queen's laying?

AMES' DOUBLE TOP-BAR.

Comparing this with the single thick bar, it has the advantage of the space for winter passage, and it can be applied to frames already in use. For new frames it will have no advantage but the winter passage, and will have the disadvantage of being more difficult to make and to put together, and not so solidly square. I think there may be another advantage in the double bar; and that is, that a queen may be less likely to go up. Baldridge's double bar, on page 205, is much the same thing. But if the space in the double bar is filled up with brace-combs I suspect the queen will go above more readily than over a solid bar. And the bees will fill the space with brace-combs just as surely as when a honey-board is used, if all dimensions are the same. Baldridge's $\frac{1}{4}$ -inch space may make the difference, and Ames' $1\frac{1}{2}$ width may also be effective. If, by having the right-sized space, or the right width and spacing, the double bar is found better than the single one, could we not retain the advantages of both by making a solid top-bar, and then running a saw-kerf through the middle of the top-bar, leaving the middle and the two ends solid?

HOW TO CALCULATE SPACING.

I want to call attention to a mistake that is somewhat common—that of dividing the inside width of a hive into as many spaces as there are combs, to find how far the combs are from center to center. An illustration may be found on page 137 in the letter of T. K. Massie. He figures that, when ten frames are in a Simplicity hive (which is $14\frac{1}{4}$ inches wide), the frames are $1\frac{1}{8}$ from center to center. That is correct, if the outside frame at one side touches the side of the hive. That is, he has simply divided the $14\frac{1}{4}$ inches into ten parts, whereas there are ten top-bars and eleven spaces. Take ten times $\frac{1}{8}$ for the ten top-bars, out of the $14\frac{1}{4}$ inches, and you have $5\frac{1}{4}$ inches left for the eleven spaces, or $\frac{1}{2}$ inch for each space. Now add $\frac{1}{2}$ and $\frac{1}{8}$, and you have $1\frac{1}{8}$ as the distance from center to center of the frames in the ten-frame Simplicity hive, just as stated in the A B C. If 11 frames are used, the distance from center to center will be $1\frac{3}{8}$ instead of $1\frac{1}{8}$. This is counting $\frac{1}{8}$ as the width of the top-bar. There will be a shade of difference if the top-bar differs.

C. C. MILLER.

Marengo, Ill., April 15.

Well, doctor, I confess I had forgotten that the ten-frame Langstroth hive does space the frames $1\frac{1}{8}$ —that is, even though I put it so in the A B C, in our recent discussions I had somehow forgotten it. Isn't it refreshing to know that father Langstroth decided so many of these things with so much wisdom years ago? After all our

ramblings and new inventions, every little while we have to come back again to Langstroth. In regard to double top-bars, see editorial in our previous issue, page 389.

RAMBLE NO. 24.

IN MONTGOMERY CO., N. Y.

EARLY in December last, the Rambler dropped quietly off the West Shore train at Fort Plain, Montgomery Co., N. Y., and found that Sprout Brook, the home of the Van Deusens, of flat-bottom-foundation fame, was eight miles away. Mud was the chief staple on the surface of the earth then, and we hesitated to embark by stage, and travel so far inland. We were, however, in search of things new and novel; and though the roads were as bad as any we ever saw, we do not regret our trip.

Sprout Brook is a charming little village with a church, a store or two, and a hotel. Nearly a mile from the village lives Mr. J. Van Deusen and his sons J. A., O. J., and C. C. The homes of the Van Deusens and their factory are located in a flat-bottomed valley, and form a very picturesque little village as you look down upon it from the hill. A stream winds its way slowly along through this valley, and years ago the water-power here was utilized to run a woolen-factory. But since the advent of improved bee culture, the woolen machinery has been taken out and flat-bottom-foundation machinery put in. Like all country streams, the water fails during dry seasons, and an engine has been added to keep the wheels of business running at such times.

The Rambler's call was made at an unfortunate time, as the elder Van Deusen had just buried his wife, and was that day from home. C. C. was confined to his bed by a severe sickness; and as he was the apiarist of the establishment, our bee-talk with the others was of short duration.

C. C. has charge of about 300 colonies, and he finds that the highest yields are realized when only 40 colonies are located in a given field. Basswood is not abundant, but clover and kindred flowers give that Mohawk and Cherry Valley honey, which is hardly surpassed by that produced in any other locality in the country. Cellar wintering is practiced by nearly all bee-keepers in this portion of the State, with usually good results. Flat-bottom foundation is, however, the great specialty, and is manufactured in a large building. J. Van Deusen and two of the sons devote their attention to this work.

The venerable and pleasant face of J. Van Deusen is well known at our conventions, and is always supplemented with a sample of beautiful flat-bottomed foundation in his hand. His position in the firm is to work up trade, attend to correspondence, and take in the cash.

On the first floor of the factory is an engine, saw-tables, planers, etc., used for the manufacture of packing-boxes for the foundation, which is manufactured in the upper story. Flat-bottomed foundation is a patented article, but it seems that patent-laws are not strong enough to protect the manufacturers, and great secrecy environs the second floor of the factory, which is rigidly closed against

visitors, and especially against ramblers. The Van Deusens, of course, claim to make the best foundation in the world, and advocate the idea that any foundation that runs less than 12 square feet to the pound, and is not flat-bottomed, is not fit for comb honey. They also lay the broad claim that it is worked out quicker than any other foundation made. Their method of cleansing the wax makes it cleaner than any other manufacturers can possibly get it; but we shall have to take Bro. Van Deusen's word for it, for their process is a secret.

For a lubricant, lye, starch, soap, etc., were vigorously condemned, and pronounced detrimental to the production of a good article. Their lubricant is as pure as the breath of an angel, and is also just as secret. Theirs are the only rolls that can manufacture wired foundation. As to how it is done is also—a secret!

Foundation can be made faster than by any other process. No visitor, however, is allowed to see the process—it is a secret! The fact, however, that foundation could be made so very fast, gave the Rambler a great desire to compare the two systems of manufacture—the secret one of the Van Deusens and the free-to-all, broad-minded system of the Dadants, who make over 30 tons per year. So we ventured a question to that effect.

"Oh, yes!" says Bro. Van D., with his blandest smile; "that reminds me of a story Capt. Hetherington told me the other day. He had a pile of wood, and employed a laboring man to saw it, supposing he had enough to keep the man busy all day. About noon, the man, whom we will call Sam, came around and reported the pile sawed. Capt. H. could hardly believe Sam, and went to see for himself. 'Why,' said Sam, 'if you want me to work all day, get a pile of wood. I want no little pile like that!' 'Well, Sam, how big a pile shall I get you?' 'Oh!' said Sam, 'get a big pile—a great big one.' 'But, how big—how many cords? what do you call a great big pile?' 'Why, Capt. H., if you want to see me everlastingly work, just get an *all-fired* big pile.' Well, Mr. Rambler, that's just the size of the pile of flat-bottom foundation we manufacture."

Silence fell upon us for the space of a minute. We realized that we had hit another secret square on the head.

There was one point, however, upon which there was no secret. This was a desire to sell this secret flat-bottom foundation, either by the pound or by the ton. The Rambler was inclined to make a bargain for a few hundred pounds, but just then the stage arrived, and we bade good-

THE GENESIS OF FLAT-BOTTOMED FOUNDATION.

by to the senior Van D., and were again behind tired horses and on bad roads. The Rambler's dreams troubled him again, and the very genesis of flat-bottom foundation came up before him, and would not down until the pencil made the vision perma-

nent. He hopes no secrets are divulged thereby, for to tell secrets or to burglarize is not the forte of the

RAMBLER.

Friend R., I am afraid that you trespass a little on the good nature of our Van Deusen friends. I am somewhat acquainted with the father; and, as you say, I have found him a most pleasant and genial man. Most of us have our peculiarities and eccentricities, and our Van Deusen friends are no exception. While I should not quite agree with them in regard to the importance of keeping their discoveries secret, I think we can respect their wishes in this matter, especially when they produce so nice an article of foundation, and at a reasonable price. With their machinery they can doubtless make a very great quantity in a year if called for; but perhaps they could not work at a much lower price and still keep up the quality. We have been selling more or less of their product for several years past. They not only send out a beautiful, uniform quality of wax, but they will make sheets two feet wide or more, and make it just as thin, or thinner, than we roll our narrowest strips. I have been told that their rolls are made of brass, and of large size, so as to allow of no springing in the center. Will our good friend Capt. Hetherington tell his man Sam that there is a good opening for just such a chap as he describes, in our own neighborhood?

A BEGINNER'S EXPERIENCE.

DOWN AT THE FEET OF THE LADDER; FALLEN PRIDE.

Dear Mr. Root:—I am down at the "feet" of the ladder again, in the bee-business. Last fall I got a handsome, little, select tested Italian queen of you, and she did nobly. I placed great store by her, and anticipated the busy brood which she would turn out this coming summer. I put three nice swarms away in the cellar, to winter; and when anybody said "bees," I would give him a cordial invitation to see mine by candlelight. Alas for human expectations! They tumble about one's ears daily, and we build only to see our fabrics fall in shapeless ruin, so often that one wonders at the fallibility of all earthly things, and grows skeptical in contemplating the utter depravity of inanimate objects.

In February, contrary to all precedent and the laws in such cases made and provided, we had a warm spell right up here in the Rockies, where it is always supposed that winter lasts 9 months, and the other three are late in the fall. A huge snow-drift had made it necessary to sink a shaft to find the cellar-door, to fish out potatoes, and, incidentally, "to see how the bees were doing." The warm spell cleared the ground of snow, all except the deep drifts, and my cellar got too warm. The moisture settled in huge drops, all over the combs, and every thing molded; and one day, when I had managed to get that refractory cellar-door open, I found, to my amazement, two of the swarms entirely dead. I hoisted the other one out, and set it in a sheltered nook, and sat down to contemplate the spectacle of about half a bushel of dead bees, and my lovely little queen, beyond the reach of mortal aid. Too much care, too much solicitude to

have them warm and comfortable like some pet horse or cow, had done the work. Better have left them out to endure the rigors of a Rocky Mountain winter than this coreseting and consequent death. It taught me a whole lot—those brief moments of sad contemplation, and I said, "Whatever I do in future, I intend to see that you don't get too warm."

I am now just where I started last spring—about a quart of bees, and a queen to come from the Home of the Honey-bees, to build up my ruined fortunes. But, in the language of Mrs. Collins, of Chapman, Neb., "I am going to succeed, if I have sense enough." We look for a wet season, and, consequently, plenty of grass, and flowers in profusion. It would do your soul good to see this country during a wet season. The ground is carpeted with flowers, and grass, so green and inviting, against the background of sage brush. Commend me to "Jotham's wife." I like her sentiments. Man should not be measured but by his worth to his fellow-man, and I respect and esteem the man who grooms horses, or the girl who waits or bakes or scrubs far more, often, than I do the people for whom she labors. The bane of this world is selfishness. I used to pride myself on the uprightness of my character and conduct, and point to my career as so much better than my neighbors'. Something wrought a change—I won't say what—and I began a microscopic examination of self. I found out that my idol (myself) had feet of clay, and I took a hammer (metaphorically), and smashed it to smithereens. I found myself to be one of the most capacious, selfish mortals living. I found that I exacted from my family the best seat, the choicest morsels, and the best of every thing, all of which I took with the utmost self-complacency without a thought or a care for other people's comfort, where mine was concerned. I did not realize all this in a minute nor a day; but when I *did* come to see myself in a proper light, there was any thing but pleasure in contemplating the spectacle. "What am I, that I should demand or accept these things of my family, or any one else?" thought I, in the bitterness of fallen pride, over a cherished character, so much better than my neighbors'. I saw plainly, that, in nine out of ten instances, I wasn't really half as good as men whom I had looked upon with contempt. At this time I do not allow my wife or any of my children to vacate a seat or surrender a paper to me until they have no further use for either. I do not think that I am doing right, if I let any one inconvenience himself in the least for my sake; but, on the other hand, I am trying to learn to render, without recompense, all the service to humanity that lies in my power. I haven't reached a point yet when I am fit to have a pair of wings grafted on, but I am not the selfish, exacting, disagreeable brute that I used to be. If a man will just turn the telescope upon himself, instead of upon his neighbors and the world generally, he will find it a mighty interesting—if, perhaps, unpleasant—study for a while, and then he will feel a good deal like going out and hiring a six-footer to kick him for about six consecutive hours.

J. F. CRAWFORD.

Saratoga, Wyoming, Apr. 22.

I am sure, friend C., we all sympathize with you deeply in the loss of your last colony, away up in the Rockies. Don't you think you had better follow our plan of wintering bees right in the open air?—I felt

deeply interested in your account of your fighting the battle in putting down self; but I confess that I felt somewhat disappointed that you did not make some allusion to Him who lived a human life, and "pleased not himself." How can you help thinking of those words, "Whoso will be chief among you, let him be your servant"?"

FROM THE LAND OF THE PHARAOHS.

FRIEND BALDENSPERGER INFRINGES UPON MERRYBANKS' WOODEN-PAIL BEE-HIVE.

The "haj" Mustapha, as the title "haj" is called, was a devout man, and had performed his pilgrimage to Mecca, on return from which the pilgrim (that is the literal translation of the word) receives the name of "pilgrim," or "haj," and is then expected to perform his five prayers daily. An omitted prayer may be recalled by saying two prayers next day at the time missed. The five prayers are to be said at daybreak, midday, four o'clock, sunset, and about 9 P. M., always facing Mecca while saying the prayers. My host declined saying his prayers that day; as he thought it would keep me too long, he would do it next day.

He then went on describing the way he makes his hives. I should certainly note down every thing, as this is a very important question in apiculture. The wooden model is five spans long (46 inches), being 8 inches in diameter. The mud is brought, mixed with one-third of fresh horse manure. After being well worked it is left to leaven for a few days. A very pliable but strong mat made of spliced reed is put down on the floor, on which dry and finely pounded manure is strewn. The above-named composition is now fully besmeared on this stout reed mat, and again dry manure is strewn on. The round model is now laid down on the composition, and by means of the mat, or outer inclosure, the mud is put round the model, and put upright, when the inner model is taken out. With an empty jug having just the same diameter as the inside of the hive, he rubs the inside up and down till it is smooth. The mat is now carefully taken away, and the finished but delicate hive is put away to dry in the sun. When wanted for bees, two round covers, always in readiness, are taken; and after having put in the five above-named combs, the swarm is put in, and is pretty sure to thrive, as swarms are admitted only in the flowery season. The hives are now laid side by side; and before a second layer is put on, the hollow space formed by the two hives is filled with sand and fine manure. When the second layer of hives is put on, the holes formed below the hives are stuffed with hemp, and all the surface is besmeared, making it mouse and moth proof.

In cutting out the honey he is very careful not to cut into the comb lest the hive get soiled inside; besides, the refuse pieces must, together with the honey, raise the wax-moth. He always leaves five combs in each hive, thus enabling the bees to store away, besides what is left, food for the flowerless season; for of a winter, hardly a mention can be made. He operates on his hundreds of hives without using any protection for his hands. He does not know that people in Europe and America dread the very name of Egyptian bees, neither does he know that any have been tried in those countries, and probably does not know that there is any dif-

ference in temperament or in color. In the middle of August, at the overflowing of the Nile, the hornets appear, in very small numbers; but by and by they increase to thousands. He boils 2 lbs. of honey and 1 lb. of arsenic; and when well mixed he takes a number of feathers, besmeared with this mixture, and sticks them in the hornets' nests. He does the same thing round about all the villages where he has any business transaction, putting also some in plates in front of the apiaries, thus killing numbers.

By this time dinner was ready. My host and myself were seated on an elevated place in the court. It being a cloudy day we were in the open air. On a copper tray were presented, on different dishes—eggs, olives, dates, and omelet bread. We used our hands, as is the custom, while a man kept driving away the flies from ourselves and food. Before eating we had to say, "In the name of God the merciful;" after food, "Thanks to God." After having thanked my bee-friend in the most courteous manner, I rode home toward Cairo on donkey-back, as I came here, very glad to have seen Egypt still flourishing. PH. J. BALDENSPERGER.

Jaffa, Syria, April 3.

Why, friend B. I just held my breath when you spoke about those cylindrical hives made of clay; and I confess I felt greatly disappointed because you did not tell us more particularly how he cuts those round combs out of the cylinders, and how he puts them back again, or doesn't he ever put them back? and is the surplus honey stored in round cakes so it can be cut into pieces like pie, as pictured in our little book, Merrybanks and his Neighbor? I have always felt a little hurt to think my brilliant idea of using water-pails for bee-hives has met with so little favor, not only in our own country, but even in foreign lands. Now, if I ever go to Egypt I shall greatly enjoy their custom of asking a blessing before they partake of food, and giving thanks afterward.

AMONG THE MANGROVE ISLANDS.

EXPERIENCE IN MOVING BEES ON THE WATER.

Two or three years ago my friend O. O. Poppleton suggested to me the idea of moving our bees to the coast, twenty-five miles from home, to get the benefit of the mangrove honey which comes after the honey season is over in the interior. With many doubts in regard to the prospective profits of the venture, we finally decided to make the trial during the past season. In the first place we had to build new hives, as the old ones were not safe to move bees in. The common pine lumber of Florida is very heavy, so we went to the extra expense of getting cypress lumber, which makes very light hives—quite an important consideration where they are moved so far. The mangrove generally blossoms from the last half of June to the fore part of August. But the season last summer was late, so that we did not move the bees till about the first of July, and that proved to be early. When we finished extracting the last of May, we left a pretty good supply of honey. This being palmetto honey it was of very good quality; and when we were ready to move the bees we took about 600 lbs. from 35 colonies, the number moved. Two frames of

honey were left in each hive. The frames were fastened at top and bottom, and what we thought would be ample screens for air were given them; honey-boards were screwed down to prevent bees from getting out, and just at night entrances were closed with wire screen. Then my son, Oscar B. (aged 19), commenced hauling them to the depot, where we had engaged a car. He worked till an hour after midnight, hauling a part about two miles, and the rest from the home apiary, nearly $\frac{3}{4}$ of a mile. In the morning two more loads had to be hauled; but we had all ready for the train, which took us safely to Smyrna by 11 A. M. We had engaged a flat-boat, or lighter, as it is called here, of friend J. Y. Detwiler, to take the bees about three miles south to the locality where we had decided to keep them. There is a strong tide in the Hillsboro River, and we had to wait till about 6 o'clock before we could have the tide with us. Then Oscar fastened our own light row-boat to the bow of the lighter, and we started, Oscar rowing as hard as he could in order to make as much speed as possible; yet darkness overtook us some time before we reached our landing. When within 80 rods of our destination the lighter ran into some oyster-bars in the darkness, and we left it while we spent half an hour in hunting for the wharf where we were to land. Then another half-hour was spent in working the lighter among a net-work of oyster-beds; and when we reached our wharf we were two tired and somewhat disgusted individuals. There was no profane language used, I believe, as neither of us had ever had any practice in that line; but I fear that we felt in a frame of mind such as some of our friends do when they use pretty strong language. Not a light was to be seen.

A NIGHT WITH MOSQUITOES AND SAND-FLIES.

Our friends had retired for the night. The path to the house was through a hummock little known to us, and it was about 60 rods to the house. Oscar said he could do no more, and, rather than try to find the road and then awaken our friends, he lay down on the wharf and slept till morning. After looking to the bees, and bailing out the lighter, I followed suit by making up a bed on top of some bee-hives. Fortunately the night was clear. We had plenty of bedding, a tent, etc., and were prepared for camping out; but the mosquitoes and sand-flies were on hand and ready for business, thousands of them. We had bee-veils over our faces, and our hands covered. We finally had to cover our faces with our blankets, all we could, and leave room to breathe. It was nearly midnight before I slept. By sunrise we had eaten our breakfast, and spent the entire day in getting the bees to land.

PURE ITALIANS BETTER FOR MOVING.

We found them all right except one colony evidently smothered, and a few bees dead in a few hives. I noticed that the pure Italians lost less than the dark hybrids. We afterward moved one colony of Italians over 25 miles in a wagon, and they made very little disturbance. The dark bees seem to get more excited, and crowd for the entrance and ventilating screen, thus shutting off the supply of air.

A POOR YIELD FROM MANGROVE.

The mangrove did not yield much honey before the 10th of July, and then the flow was not constant. It seemed to do better after a good shower of rain, while a few days of hot dry weather would be a sure indication of idleness in the apiary. We

secured only about 600 lbs. of honey, and the last of that was undoubtedly mixed with cabbage-palmetto honey, which is also a very light-colored honey, and of fine flavor. Every bee-keeper with whom I talked upon the subject said it was one of the poorest seasons for honey ever known. Some thought that the yield is always light when the mangrove-blossoms are so late in the season. In counting the profits of our experiment, the 600 lbs. of palmetto honey taken before moving would have to be added to the 600 of mangrove, as we could not have extracted the palmetto honey had the bees been left at home; 1200 lbs. at 7 cents, what we have been getting for most of our honey in our home market, would give \$84.00. Less cash expense of moving, \$24.00, would leave about \$60 for our labor—not very high wages, certainly. Large quantities of honey could not be disposed of at 7 cents per pound. One bee-keeper shipped several barrels to the North, and realized only 4 cts. Another sold 8 or 10 barrels at home for 5 cents. We left the bees at the coast till December. The last time we extracted, which was during the first half of August, we left plenty of honey in the hives. Some honey was to be had from various flowers, but not enough for the needs of daily consumption; and by the last of October there was very little left. It looked as though the bees would have to be fed or starve. Oscar and I went over to look after them about the first of November, and found them storing

HONEY FROM SAW-PALMETTO BERRIES.

This product is more like a poor quality of syrup than honey; but the bees seemed to thrive on it. We concluded to let them work away while we took a two weeks' trip 50 or 60 miles north on the Halifax River, and Smith's Bulow, and Tamaka Creeks, camping out and adding to our collections in botany and conchology. On our return we found the bees still storing from the palmetto-berries, so we left them a few weeks longer. When we moved them home in December the hives were quite heavy with honey. I am satisfied that, had it not been for the palmetto-berries, we should either have been obliged to feed the bees for a long time, or let them starve. The palmetto is said not to yield a crop of berries every year.

WOOD-ANTS.

We lost two colonies from robbing, and two from attacks of the large wood-ant that is sometimes so destructive to bees near the coast. Had we been with the bees we could have saved those four colonies. The ants can be destroyed by following them to their hiding-places. Those that did the mischief for us first made their nests in the top of the hives; and when they got pretty strong they commenced killing, and, I think, eating the bees. I saved one colony they had commenced on. In one corner of the hive there was about a pint of dead bees with wings torn off, and the bees torn to pieces. The rest of the bees were on the combs all right, and I was satisfied that the ants were eating a few every day. I brushed the ants out of the hive, and a flock of chickens snapped them up as fast as they struck the ground. They made no more trouble in that hive. The hives were set on large spikes, and the spikes in cans of water; but the cans got empty, and the ants found their way into the hives. They work only at night, remaining hid during the day.

On the whole it is hard telling whether our experiment paid us in any way except in the experience gained or not. I have no doubt that, in a good

season, we should have felt well paid for our trouble.

MOVING BEES FROM THE NORTH TO FLORIDA NOT RECOMMENDED.

Some parties have talked of moving bees from the North to Florida, to get our winter flow of honey, and especially orange honey. I do not know whether any one has done so or not; but I will venture the opinion that they will do it but once.

PRESENT OUTLOOK FOR FLORIDA NOT ENCOURAGING.

The present honey season in Florida is likely to be a very disastrous one. The winter was very warm and dry, and we got no honey. The 1st day of March we had a good rain, followed the next night by the first frost of the season. In two weeks came another frost that did great damage throughout the entire South. Thousands of acres of tomatoes and other tender plants just ready for market were cut to the ground. In many places young orange-trees were killed to the ground, and orange and many other honey-yielding blossoms were destroyed, leaving nothing for the bees. The winter had been so warm that most things had started to grow. The consequence will be, that our Northern friends will not have so many oranges from Florida the coming season. In the interior, bees will probably have to be fed during the whole season or else starve. Saw-palmetto generally blossoms about May, but it throws out its long panicles of buds long before that time, and most of them were killed where they were not protected by the leaves. We have been feeding our bees up to the present time. I have not learned what the prospect is for mangrove honey.

GEO. W. WEBSTER.

Florida, May 10.

DR. C. C. MILLER.

BY THE HALF-TONE PROCESS.

A short time ago we received information that Mrs. Miller did not like the wood engraving of her husband, Dr. C. C. Miller, in the A B C of Bee Culture. The cut was very good, but it was not exactly natural around the eyes and mouth. We accordingly have had another one made by the half-tone process; hence I take pleasure in again introducing our old friend and correspondent, Dr. C. C. Miller, of Marengo, Ill.

It is almost unnecessary to tell who the doctor is, or what claims he has on the hearts of bee-keepers. We can say of him as we can say of very few bee-keepers, he has no enemies. In fact, it would be a very hard matter to quarrel with him or make him talk back. He sometimes, like Dr. Mason, has a blunt way of talking in conventions, for the sake of a joke.

There are several men who always help materially in making a good convention. Not mentioning the others, I will say Dr. Miller is one of them. I remember, at the International, at Brantford, everybody inquired, "Where is Dr. Miller?" or, "We need him."

We hold Dr. Miller, here at the Home of the Honey-bees, in very high esteem, not only as a personal friend, but for his opinions upon any phase of the subject of bee culture. He has twice revised the A B C book, and twice added his comments in the

back portion of the work. In fact, he is consulted in regard to this, that, or the other improvement in hives and other appurtenances. Very often, when a new thing comes up that I think is going to displace every thing else, I write to Dr. Miller, and ask him to find all the fault he can with it.

DR. C. C. MILLER.

And his criticism is generally heeded. Our correspondence in GLEANINGS shows that we do not always agree; but the fact that he is so often consulted is somewhat of a measure of the value we place upon what he says.

If some of our new subscribers want to know when and where he was born, whether he is short or tall, broad or slim, I would refer them to a short biographical sketch by the writer, in the A B C of Bee Culture.

ERNEST.

CALIFORNIA.

BACKWARD SPRING.

Bees have wintered well in this part of the country. No losses, except where they starve, and not many of them so far. The spring has been very unfavorable up to date. There have been but few days that bees gathered any honey. Rain, rain, rain, is the order of the day. Our spring was like yours last year. There were only two days when bees could work on apple-blossoms. In my apiary they are destroying the drone larvae, and expelling the mature drones. The queens have slacked laying, yet I am feeding whenever bees can fly.

I fear that I shall not get bees enough to get much surplus, if this weather continues much longer. I am feeding sorghum, diluted to thin syrup, placing it about two rods from the hive. There is no fighting or robbing among the bees.

S. L. CRAIG.

Oakland, Cal., May 14, 1890.

MANUM AND THE COMMISSION MEN.

HOW HE MANAGED TO SELL \$4000 WORTH OF HONEY BEFORE BREAKFAST.

I HAVE seen articles in GLEANINGS from time to time on marketing honey. Several of your readers have given their experience and advice on this important subject, and it may not be out of place that I should give my experience with commission men. I have never been fully satisfied with the practice of sending my honey to be sold on commission. Though I have never, but once, been able to sell it outright, I have tried very hard to induce parties to get in the habit of buying honey as they do other farm produce. But they seem to be a little loth to do so, as they say honey is a luxury and not a staple article.

A few years ago I shipped my honey to a firm in Boston, known as Favor & Dudley, who then handled nearly all of our Vermont honey. While in Boston one day, looking after the sale of my honey, I chanced to pass a store, in front of which I saw several cases of my honey piled up to attract attention. I looked up to the sign over the door, which read, B. F. Southwick & Co.; and as I was looking at the honey, a fine-looking gentleman stepped out and smilingly saluted me with, "Good-morning, sir." This proved to be Mr. Robinson, one of the firm, who asked:

"Do you wish to buy honey, sir?" said he.

"No, sir; I was simply admiring it. Do you handle very much honey, Mr. R.?"

"Yes; we sold 50 cases of this brand last year, and this year we have so far bought 50 more, and hope to be able to sell 100 this season."

"Do you consider this brand as good as any?"

"Yes, we prefer it to any on the market. As it is put up in such nice, clean, and attractive packages, we sell it as a *fancy* article."

Here he opened a case, took out a section, and, holding it up, salesman fashion, he remarked:

"There, see how nice and clear it looks. Why, I tell you this is *fancy*, and it sells like hot cakes."

"You buy this honey outright, I suppose, Mr. R.?"

"Yes, we buy it of commission men; but we should be glad to handle all of this brand if we could arrange to do so."

"I see this is Vermont honey."

"Yes, it is; and, like Vermont butter, it stands at the head."

At this point I handed him my card.

"What! is this Mr. Manum? Are you the man that produced this honey?"

"Yes, sir, I suppose I am."

"Well, you are the very man we want to see. Please step into the office. Mr. Southwick, this is Mr. Manum, who produces such nice honey."

"Well, Mr. M., I am glad to meet you. We were speaking of you this morning, and wishing we might see you. Have you any more honey to sell? We should prefer to buy of the producer direct."

"Yes, sir, I have about 200 cases more."

"Oh! that is more than we wish to buy at *one* time; but we will take it on commission, and do the best we can for you."

"Well, gentlemen, I am here for the purpose of *selling* my honey. I do not like the commission business. I am sick of it, and surely I ought to be able to find some one in this great city who will buy so little as 200 cases."

"Mr. M., you had better consign it to us, and try us. We will do our best to please you. We are commission merchants, but we have never had a consignment of honey, though we should like to have you try us."

"Very well; then I will ship you what I have, on my return home."

This I did, and I was satisfied with the returns. I shipped them my entire crop the next year, though it was a light one—only four tons; but this seems to have set them up in the honey business, so that to-day B. F. Southwick & Co. are the leading honey merchants in Boston.

The following year I shipped them four tons early; and before I got the rest of my crop ready to ship, the old notion—of selling outright rather than placing it on commission—returned; and, being so strongly impressed that this was the true way for bee-keepers to do, I went to Boston with the determination to sell, if possible, to some party, and try to get them in the habit of buying rather than to take it on commission. So I called on my friends, B. F. S. & Co., for that purpose, but they talked very discouragingly. So I called on several other merchants, and in two days I succeeded in finding four parties who would buy six tons at a certain price—which was less than my price—but closed no trade with either of them. I returned to B. F. S. & Co., and made another desperate effort to sell them the remainder of my crop, which was now reduced to about 11 tons. I told them how I had found four men who would take six tons.

"What! do you propose to sell a portion of your honey, and then consign to us what you can't sell?"

"That is just it, Mr. Robinson. I shall either consign the rest to you or to some one else. But I want to sell you the entire lot; and now I will make you a proposition: That you come to Vermont with me and see the honey; and if you do not buy it I will pay your fare back, so that you will be out only \$6.50. But if you buy the honey you shall pay your own expenses up and back. Your expenses while there will be nothing, if you can put up with such fare as my wife can offer you. You see, I am determined to induce you Boston fellows to buy our Vermont honey outright."

"Well, Mr. M., your offer is a fair one; but it is too large a lot for us to buy at once."

"Very well; then I will return home on the next train, and I will decide in a few days what to do with my honey."

An hour later, as I had just taken a seat in the car, and as the train was just moving out of the depot, I felt a heavy hand on my shoulder. Looking up, there stood Mr. R., so much out of breath that he could hardly speak; but he managed to say:

"Mr. M., I am going home with you to see that honey. After you left our store, Mr. S. and myself talked the matter over, and we decided that I should go up and see the honey, if I could catch the train, which you see I have just barely done. As I was never in Vermont, I thought it a good time to take a look at your Green Mountains."

As we came via the C. V. R. R., we had a long ride through New Hampshire; and when White River Junction was reached I told Mr. Robinson that we were in Vermont; and I wish, Mr. Root, that I had the ability to describe Mr. R.'s enthusiasm as we glided along up White River, with the Green Mountains on either hand looming up skyward, with a seeming desire to steal a kiss from the

flying clouds as they journeyed onward, paying their respects to the old mountains only by occasionally saluting them with a light shadow as they skipped over the bald heads of these gigantic and aged mountains. Suffice it to say, Mr. R. was wild with delight and admiration as we skipped along from bridge to bridge and curve to curve until we reached Bristol in the evening; and while Mrs. M. was preparing supper, Mr. R. inquired whether the honey was near the house, so he could see it that night. Although Mr. R. had been under excitement all day, and must have been very tired, his great energy and business habits would not permit him to retire without first taking a look at the honey. So, after satisfying our appetites I conducted him to the honey-room, at the rear of the house.

Although Mr. R. is a very shrewd and thorough business man, I very soon made up my mind that he would buy my honey before he left. The next morning he was up and in the honey-room by daylight. After doing a few chores—more to allow him to be by himself than for the chores themselves—I joined him just as the bell rang for breakfast.

"Good-morning, Mr. R. I see you are making some figures. Does it figure to suit you?"

"Well, yes; but can't you make your price half a cent less?"

"No, Mr. R., I have already given you half a cent on a pound, in order to induce you to buy the honey. You will see that, by giving you the half-cent which I have, and if there are 11 tons, you are getting \$110 for your trouble in coming up here. But, our breakfast is ready; let us go in."

"How soon can you ship the honey?"

"I think we can get it ready in a week."

"Very well; then I will take it at your price, and send you a check for the amount on receipt of the honey. Well, Mrs. M., I have made a \$4000 trade with your husband this morning, before breakfast."

"Have you bought the honey?"

"I have; and Mr. M. says I must stay a few days and help him to grade it."

"We shall be pleased to have you; and I dare say you will enjoy the business, while your advice may be beneficial to my husband in the matter of putting up honey in the most practical style to suit your market."

Breakfast over, we returned to the honey-room, where the help had arrived, and we commenced work; and after watching the various manipulations of the honey as it was being prepared for shipment, from the scraping of the sections to the crating and weighing, Mr. R. looked up to me with a smile, and said:

"Mr. Manum, I want to work a little at each part of this work, for the purpose of knowing how it is done."

"Very well; you may commence by scraping one clamp of sections, and you may occupy this girl's place while doing so. In the mean time I will find something else for her to do. But, first, she may teach you how to clean one section while I go and catch a few queens to fill an order received last night."

I had caught but one queen when I heard a great uproar and laughter in the honey-room. I will here state that Mr. R. has a very agreeable, lively, and cheerful nature, and he enjoys a good time as well as the next one, and especially a good joke, whether he is the victim or not. Upon hearing the

uproar I hastened to the honey-house to learn its cause and to enjoy the sport myself. As I entered the room I found all the girls standing, and in a fit of laughter, as well as those from the other rooms. All were looking at Mr. R., who, it seems, had punched a hole in a section of honey with his finger; and while holding it up to decide what to do with the "leaky thing," as he termed it, he dropped it on the floor, and of course smashed it; and it was his looks of despair at his ill luck which caused the girls to laugh so heartily. He finished his clamp of sections, however, in a creditable manner, and disappeared for a time. Where he could have gone, no one knew; but he soon reappeared with a large package of choice candy, which he placed at the disposal of the girls, saying, at the same time, that the best way to close a girl's mouth was to sweeten it. This he did very effectually, for the girls did not again mention to him the broken section of honey, and he was at once considered the hero of the company.

Mr. Robinson progressed finely in the different branches of the work, until he was at last promoted to the delicate work of grading; and I found him perfectly at home in this work. His experience in selling honey had taught him how this should be done; and instead of being his tutor, I found myself his interested pupil, greatly to my advantage ever since.

After watching Mr. R. a few moments I asked him if he thought it was best to grade the No. 1 as close as he was doing. His answer was, "Yes, most assuredly;" and he remarked:

"Now, Mr. M., I want to impress upon your mind the importance of careful grading. For instance, you should always be careful to have every section in each grade be true to that grade. Never allow a single section of No. 2 to go in with No. 1, or No. 3 with No. 2, and so on; because if a single section of No. 2 is found in a crate marked No. 1, the whole crate will have to be sold as No. 2, notwithstanding it contains but one section of No. 2. This rule holds good with fruits, vegetables, and all kinds of goods. All should be true to name and grade. Honest goods will always sell and command the highest price. Therefore work for a reputation; and when once gained, strive to keep it, because a lost reputation is much harder to regain than to have kept it. Therefore be watchful, and send us honest goods, and I will guarantee that you will always be pleased with the result."

After spending two days with us, Mr. R. left for his home; and on taking his departure he declared that he had enjoyed himself exceedingly well; saying that he could now tell his customers all about the honey-business, as he had been where it was produced, and worked at the business with his own hands, and that he knew that it was strictly pure.

On taking his leave of the family, Mrs. M. presented him with a well-filled lunch-basket, saying to him that the contents of the basket might be acceptable to him before he reached home. This little gift, representing her motherly nature, made such an impression upon his mind that even to this day it seems to be one of the pleasantest remembrances of his first visit to Vermont; and to assure us of that fact, he has, every year since, forwarded us a well-filled box of choice goods from their large assortment, as a token of his appreciation of that lunch-basket, and his regards for the giver who has since gone to her long home.

Notwithstanding B. F. Southwick & Co. did well with the honey I sold them that year, I have never been able to sell them any since, owing to the fact that, since then, the price has been so fluctuating, and also that the bee-keepers of New England seem to prefer to consign their honey, or, at least, they do so without making any attempt to sell outright, and I have found it rather up-hill business to establish the custom above; hence I have been obliged to consign my honey each year since the year above referred to. Although Messrs. B. F. S. & Co. have, so far as I know, been square and honorable with me, and make quick returns, I should much prefer to sell my honey at home, and have it done with.

Bristol, Vt.

A. E. MANUM.

Well done, old friend. Why, you will get able to write a book if you keep on at this rate. Now, there is one great moral in your very interesting story. It is this: There is nothing that helps a man to sell goods like being very conversant with the details of the commodity he is handling. And the emphatic injunction in regard to honest grading is a great truth. A reputation is much easier lost than gained, and much harder to be gained when lost than to have kept it.

RIPENING OF EXTRACTED HONEY.

ARTIFICIALLY RIPENED JUST AS GOOD AS THE HONEY RIPENED IN THE HIVE.

MR. HOLTERMANN, on page 87, says that the color of honey is probably affected by being stored in dark combs. Further on he tells us he leaves his honey intended for exhibition on the hive until a few days before such exhibition, and then extracts it. In this way, he says, he secures the ripest honey, and that "no one will admit that honey some time off the hive and out of the comb is of any better flavor than that just taken off; and further, that such honey is not affected as to color, if stored in white combs.

There are several mistakes in the above, I think. At least *one* man does admit and argue that honey may be improved off the hive, and, indeed, should be. I would call Mr. Holtermann's attention to my former article on page 48, Jan. 15. In addition I will add a few thoughts.

In his foot-note, the editor corroborates what I have quoted. He says that well-ripened honey is less liable to candy than that which is extracted before it is sealed. That the most thoroughly ripened honey is the last to candy, other things being equal, I agree. But to the idea that it must be extracted before it is ripened, I say emphatically, no. Last summer I extracted my first honey near the close of the wet spell we had in June. During that period, honey came in about as thin and rank as I ever tasted it. Nearly half of this honey was unsealed. I put it in lard-cans and stone jars, covered with cloth, and set them where the sun would pour in through the south window upon them, and left the honey to *cook*. In the fall this was among the thickest, richest honey I had, and the last to candy. And why should it not be so? If honey ripens by staying on the hive, what is it that does the work? What is the process of ripening honey, any way? Does it not consist in evaporating the water and intensifying the body of the honey? Is it not this concentration of the essential elements of honey

that constitutes its richness? And if so in either case, are not the conditions essential to this ripening process as well secured in a warm dry honey-house as in the hive? I claim from experience that they are present to even a greater degree. I see no way out of this conclusion unless it be in the vague, improbable guess that some chemical change takes place in the hive. I do not say that honey will not ripen in the hive, but I do say that the essential conditions—heat and dryness—must be present. In other words, the hive must stand in the sun, and be as near proof against outside dampness as possible. Honey remaining on hives densely shaded keeps thin, and acquires that moldy flavor spoken of by the editor on page 49.

THE COLORING OF HONEY.

Now a word as to the coloring of honey. That honey standing long in old black combs will become dark, is no doubt true. But it will do the same thing in new combs. I have put two sections of honey in a dish, one of which was beautifully white, the other considerably travel-stained from remaining on the hive. When they were cut into, the honey in the travel-stained comb was perceptibly darker than that in the others. This, coupled with the fact that honey extracted from old combs, pretty soon after it is stored, is as light as any, seems to prove that honey will turn dark by standing in the hive, whether stored in black or white combs. Now, what is the cause of this? Can it be some mysterious chemical process that goes on there? Who can throw some light on the matter?

GEORGE F. ROBBINS.

Mechanicsburg, Ill., Feb. 3.

Friend R., how large are those stone jars? I can readily imagine that, if they held not to exceed a gallon apiece, and if set in a south window, without curtains, during the hot days of July and August, the honey would evaporate or ripen until it acquired any desired thickness. And is not this a hint as to the cheapest way we can ripen raw honey? Well-ripened honey is certainly a little darker than green raw honey. I have seen basswood honey almost as clear as spring water, and so thin that you could almost drink it like spring water. When thoroughly ripened, however, it was quite dark, comparatively.

PEDDLING HONEY.

EXTRACTED; PREVENTING GRANULATION A FAILURE.

MR. J. A. BUCHANAN'S article in GLEANINGS, March 1, has called forth a few thoughts in my mind which may be of interest to the producers and sellers of honey, or, more particularly, extracted honey. If we prevent honey from candying by sealing hot, or by mixing, what shall we say to those who have been taught that pure honey granulates, and impure honey does not? and when a visitor comes to your apiary, and sees your operations, how will you prevent his being confirmed in the idea now prevalent, that all honey is bogus? Preventing granulation by sealing hot has not worked satisfactorily with me. Some one wishes to see how the honey tastes. The sealing is not done perfectly, and then your honey granulates. Consumer, who thinks it should be clear, observes with a smile, "He got too much sugar in it that

time." The one who has kept "strained honey" in the house all winter, and knows it is natural for honey to granulate in cold weather, and those we have succeeded in educating, think that you have adulterated it. It will not do, generally, to rely on the groceryman to explain to the customer. Generally he is not asked to; and in time the story gets old, and he can not spare the time on an article that sells as slowly as honey does. As Mr. B. says, we bee-keepers must solve the problem ourselves. If I had an unlimited amount of time I could sell extracted honey for 10 cts. where comb honey sells at 12; and it need not be in liquid form either. Thinking that I must change from producing extracted to comb honey two years ago, I purchased some comb honey to peddle with my extracted granulated honey, and found, to my entire satisfaction, that the trouble in selling extracted honey at the price named was less than selling comb honey. I sold 5 lbs. of the former to one of the latter. When comb and extracted honey are placed in a store, generally the result is the reverse of the above. The groceryman gets tired of talk, and sells what is "called for." Now, how shall we solve the problem of selling extracted honey? for with me in this market it must be solved or given up. The groceryman does not succeed in disposing of any worth mentioning, in the granulated form, and the task of melting and sealing hot in small glasses, and remelting what granulates again, and keeping the groceryman supplied with it in attractive form, is too great a task where you have a large crop to market and take it to grocerymen at other towns.

Waverly, Ia., Mar. 11.

J. B. COLTON.

Friend C., the honey business is full of contradictions, like almost every thing else. I know it does take a deal of talking. The best way to get rid of the talking, however, is to give your customers a real nice article; and when they call for more, give them a real nice article again.

THE HONEY MARKET OF BUFFALO.

HOW THE DEALERS THERE CALLED THE LIQUID ARTICLE "STRAINED," MANUFACTURED (?) COMB HONEY.

DURING March I was, owing to my mother's illness, suddenly called to Buffalo, N. Y., and remained there about two weeks. I took a room, and prepared my own breakfast and supper. You know a German is saying, and can live where other people starve. There is one thing I always feel breakfast is incomplete without, and that is honey. The entire year, when able, I like either extracted or comb honey for breakfast. So I ventured out, and at the grocers' made inquiries about extracted honey. The clerk or proprietor asked, "Do you mean strained honey?" and told me they had none. The remark led me to think whether it could be that, in the same country, and in so large a city as Buffalo, and within so short a distance of that great apicultural light, Dr. Mason, people did not know extracted from strained honey. I then and there determined to sift the matter thoroughly. I visited about fifteen stores, and in every case found they called it strained. I would say, "Have you comb honey?" and then would ask for "the other" kind, and in one way or another I led them to name the honey first, and the name given was always strained. In

the largest grocery store (so far as I know) in Buffalo, in Yerxi's, they called it strained; and when the young man in attendance found out I kept bees, and knew honey, he asked me if the comb honey in their store was really genuine. I then read him your offer about the manufacture of comb honey, and the efforts of the American bee-journals to stamp out the erroneous idea that comb honey could be manufactured.

Surely a man can not attain to the greatest success in the sale of goods if he has no confidence in them; and surely in that large establishment on Main St., Buffalo, a man understanding his goods, and selecting them judiciously, could surprise the proprietor by the amount of sales which could be effected in comb and extracted honey alone; and, on the other hand, what an outlet would be secured for the bee-keeper's honey! The extracted honey shown by this store had been packed in a large packing-house. I will not say it was impure, but it was not good; and owing to the fact that it had passed through several hands, the price was higher than would be necessary if it had passed from the bee-keeper direct into the hands of the retailer.

This matter is surely important. The next question is, "How shall it be remedied?" The question is a difficult one. If a store could be induced to subscribe for a good live bee-journal, much could be done to educate the salesman. Bee-keepers, too, should be wide awake, and instruct the parties to whom they sell their honey, and place them in a position to refute statements injurious to the sale of honey. An instance: A customer comes in and says, "I would buy that honey, only there is so much manufactured at the present day, I fear yours may be." The clerk, who is doubtful himself, will, if he is conscientious, shut his mouth; if not, he may say, "This is not manufactured," etc. But if he can say with confidence, "It can not be manufactured," and show there is a reward of \$1000 offered for the manufactured article, which has never been claimed, then he is likely to convince his customers, and effect a sale.

I saw friend Herschiser in Buffalo, and he stated they even called honey "evaporated," and that if people could only feel sure that honey is pure, much more would be sold. R. F. HOLTERMANN.

Romney, Ont., Apr. 23.

Friend H., what you tell us is truly astonishing, and, I might add, discouraging. By the way, you did a good thing when you started out to find out about honey. I have often done the same thing when waiting for a train in a large city, and I believe it is well worth while to canvass our towns and cities thoroughly whenever opportunity offers. It is not only on honey that clerks are often deplorably ignorant, but on many other things they handle. And here is a hint for those who are out of work, or think they do not get as much pay as they ought to. They do not read and inform themselves, and keep posted. Just talk with some of our runners for the large manufacturing establishments, and see how thoroughly they are posted, not only in regard to the goods they sell, but also in regard to the current gossip of the day, not forgetting manufactured comb honey. By the way, when you start out in a city, do not forget our reward cards.

FASTENING FRAMES AND TOP-BARS FOR SHIPMENT.

T. P. ANDREWS TELLS US HOW HE DOES IT.

THE questions, how to fasten on loose bottom-boards, and how to fasten the frames for transportation, seem to interest many who wish to move bees. Five years ago, while fixing up a carload of bees for a move, I devised and made a lot of comb-spacers, one of which (half length) I send you. By raising the front end of the hive, one of these spacers is readily slipped on to the bottoms of the frames, near the middle. Now, when you have let your hive down on to the bottom-board you have the frames fixed so there will be no swing to them.

Put one of the spacers across the top-bars, near each end, and you will have the frames secure from any movement on the rabbit. These spacers are cheaply made, quickly adjusted, and have none of the objections that are held against staples, nails, etc., driven into frames or hives.

To fasten on bottom-boards easily, securely, and cheaply, procure a lot of tins cut to about $\frac{3}{4} \times \frac{1}{2}$ in., and a supply of rather thick wire nails one inch long. Three of these tins, tacked on to each hive, one each side near the front, and one at the middle of the back end, holds the bottom-board to the body.

I drive a nail diagonally into the back end of the bottom-board, to keep the hive from slipping off when the front end is raised.

To cover the hives and at the same time give the necessary ventilation, I made frames of lath, halved together at the corners, just the size of the tops of the hives, which are not beveled. On to these cover-frames wire cloth is securely tacked. After the comb-frames are fastened, the enameled-cloth cover is slid back so as to leave an opening for air, the size of which is adapted to the strength of the colony and the warmth of the weather. The wire-cloth cover is then placed on the hive, over the enameled cloth, and fastened with four wire nails. When this is done, and the entrance closed with a cleat tacked on, the bees are in good shape to transport by wagon or rail, as I have occasion to know from a somewhat extensive experience in the use of these appliances.

T. P. ANDREWS.

Farina, Ill., March 6.

Your plan of fastening frames is very similar to the one we used last summer (see GLEANINGS, page 551, last year). The notches in our strips were not pointed.

Yours would have the advantage that they would crowd between the frames better. I don't believe I should like your method of fastening bottom-boards; it is too much work.

REMOVING QUEENS TO PREVENT SWARMING.

E. FRANCE ANSWERS A SEASONABLE QUESTION.

WHEN you remove the queen from a colony to prevent swarming, how long do you keep her out? What do you do with her in the mean time? and is there any trouble in putting her back?

The above question was handed in by one of our subscribers, for E. France. We forwarded the same to him, and he replies:

Our out-apiaries we visit only once a week. We simply cage the queens in the hive, and usually let her remain caged two weeks. The bees build queen-cells when the queen is caged, just the same as they would if the queen were taken away. We never cage more than three-fourths of the queens in the apiary, at one time, for the reason that we must have some young brood from which to raise queen-cells. After the queen has been caged one week we are on hand again to extract. It won't do to leave the queen-cells another week, so we tear them all out and give the colony at least one comb of very young bees and eggs, from which they will raise another batch of queen-cells. At the end of the second week we again destroy all queen-cells, and then liberate the queen. If we are making any new colonies at the time we are caging queens, then we would put the queens into the new colonies, and after two weeks let the old colony raise a queen. But sometimes bees will swarm with a caged queen. In that case, take the queen away, out of the hive; that will cure them, *sure*. But, remember that, if a colony has no queen, they must have something from which they can raise one; then they will work and feel happy. See GLEANINGS for 1889, p. 17.

If I were running for comb honey I would get the bees just as strong as I could without swarming; then take the queen away, give her a quart of bees and some combs, and there let her remain until the close of the honey-flow, say 20 days; then return her with her combs and brood. It would be safer to cage her for one day, but we don't do it, for by this time she has quite a nice lot of bees and brood to go with her. We have run a few colonies at home in this way for several years, and never yet have lost a queen in putting them back. Of course, the old colony that is at work all this time making comb honey must be kept supplied with brood, young enough, from which to raise a queen, and queen-cells are to be destroyed once in ten days, then give them more brood.

E. FRANCE.

Platteville, Wis., Feb. 23.

Friend F., you have struck upon one point that I didn't see. You say that bees will sometimes swarm with a caged queen; but, of course, in that case they will come right back to the hive, unless, indeed, they find some other swarm to unite with. It seems to me from the above that it does make a difference, in some respects at least, whether the queen be caged in the hive, or taken entirely away. A queen with a quart of bees can usually be returned to the hive

she came from, especially if honey is coming in, and they have no other queen hatched. At other times I think there will occasionally be trouble.

SPACING BROOD-COMBS.

HOW FAR APART SHALL WE SPACE OUR BROOD-COMBS FROM CENTER TO CENTER?

WHAT is the proper distance from center to center to space brood-combs—1½ inches? So far as I know, 1½ is all right, and I think it is the distance agreed upon by the majority. But sometimes we settle down upon something in a kind of passive way, without any special reason for it; and sometimes that turns out right, but sometimes wrong. How about this spacing business? What do we know about it? Why is 1½ better than 1¼ or 1½? I don't know; but is it not time to examine the matter a little? One of the first factors in the problem is the thickness of brood-comb. If I am not mistaken, worker comb, when first made, is ¾ thick. As successive generations of brood are raised in it, the deposits at the base of the cell increase the thickness of the septum, and wax is correspondingly added at the mouth of the cell. So, you will see, the thickness of comb, although an important factor, is not a fixed factor. Without giving the matter any special attention, I have measured worker comb a plump inch in thickness. Here an eighth of an inch has been added to the thickness; and if the comb were twice as old, would not another eighth be added? So I should not like to say that 1½ is the average thickness, only that it is constantly increasing in thickness, that thickness being limited only by the age of the comb or the room the bees have to elongate the cells. I have seen cases where I suspected the bees had gnawed down every thing to the original septum of wax, just because through age the comb had become so thick that it could be made no thicker without making the passageway between the combs too narrow. If the bees could have moved the combs further apart, I see no reason why they might not have done so and gone on thickening the combs.

But I suspect that we so seldom have comb thicker than one inch that we may base our calculations on 1½ as the thickness of comb. And here I may remark, in passing, that friend Heddon, when he said he would have top-bars only ¾ wide if he had ½ space between them, could hardly have counted much upon combs increasing in thickness with age. With top-bars ¾ wide and ½ between them, there would be 1½ space between combs when new, and that space would be constantly decreasing as the combs grew older. While the comb is new there would be barely room for two bees back to back, each hugging down tight to the comb; and when the comb becomes one inch thick there will be only ¾ between the two faces—not room enough for the queen to stand erect. Would the bees tolerate such a condition?

The next question is, What space is desirable between the faces of the combs? There is good authority for saying that there should be more space between combs in winter than in summer. For all that, I think the majority will keep the same space summer and winter, and we are left to decide what, all things considered, is best for all the year round. Suppose we have our brood-combs spaced 1½ from center to center, with a cluster large enough to oc-

cupy 8 combs. If, now, we space our combs a little less than 1½ from center to center, 10 combs will go in the same space the 8 occupied, allowing us to raise a fourth more brood with the same bees, because they can cover just that much more. But there is a still further gain; because, when we put in the two extra combs, there is just that bulk of bees displaced to occupy more combs. The 8 combs measuring 1½ each, occupy 7½ inches, leaving 4½ inches as the measure of the bees that fill the spaces. Now, suppose we space our combs 1¼ inches from center to center. Take 1½ (the thickness of the comb) from 1¼ inches, and we have ¼ as the space to be filled with bees. We have 4½ inches of bees, and these will fill 14 spaces of ¼ each. So we can have 14 combs covered by the same bees that covered the 8 combs, just by spacing them ¼ inch closer. In the same way, if we space 1¼ from center to center we shall find that, instead of 8 combs, the same bees will cover 24 combs, barring the fact that some of the bees may go into the cells. And so, the closer we space, the more brood we can raise, till—but, hold on! Another factor comes in. We can't space so close that the bees can't get between the combs to feed the babies, even if the queen had the eggs laid there. Moreover, there must be enough bees between the combs to keep up the requisite heat or the eggs will not hatch. A single bee can not hatch an egg, as a hen can; and in spring weather I don't think a single layer of bees could. So you see we gain by spacing closer, only up to a certain point. When we find just what the right point is, then spacing closer than that will leave some of our outside spaces too cold to hatch eggs, and we shall lose by it. Somewhere about 1½ from center to center is right; but I don't suppose it is *exactly* 1½. How can we find what it is? Upon that depends our spacing and the width of our hives. I suppose we need to find what is best for spring; for, after warm weather comes, it does not matter so much; and at the South, can we not space closer than at the North? I should not be surprised if some one points out factors that I have left out altogether, and I feel that it is worth while to find out all we can on this topic.

Marengo, Ill., Mar. 24.

C. C. MILLER.

Doctor, I am glad that you did think about accommodations for the nursing bees. When they are incessantly putting their heads into the cells, and backing out again, they can not afford to have cramped quarters, nor even to have somebody just behind them to hit against, every time they back out. Suppose you had to crawl into a cell to feed the children, and you were given such close alley-ways that you are striking a back wall every time you back out. Now have these alley-ways crowded with people, and see what a predicament you are in. Our packing-room has been too much like that during the past few weeks, and I tell you it pays to have more room or fewer people. I do not believe that combs ever ought to be nearer than 1½ inches; and if they are old and crooked and wavy, I am in favor of something pretty near 1½ inches. In changing combs about promiscuously, as we used to do every day and every hour, I have seen brood-combs pushed so closely together that the nurse-bees could not get in to feed the larvæ, and keep them from starving, with-

out cutting down the surface of the comb; and sometimes after having done this there was not room for the larvæ on both sides to be capped over, when they became large enough. Then our little friends had a serious problem on their hands. Now, I do not believe in putting combs too close, neither do I believe in turning them around and mixing them up promiscuously. Of course, the bees *can* adjust themselves to such bungling operations on the part of their keeper, but I am sure that it results in a loss of brood more or less, and consequently a loss of honey-gatherers when the season opens.

REMOVING THE QUEEN.

STIMULATIVE FEEDING, ETC.

I WAS surprised to read the answers in GLEANINGS regarding this question, as I often am in reference to stimulative feeding. I have tried both of these very carefully under the most painstaking caution to avoid any error—no guesswork at all. I am sure that our bees—and they are very much like other bees—do breed more rapidly when fed, in case no storing is in progress; and I am as fully convinced that removing the queen at the proper time, if done so as not to disturb the peace of the colony, will give more honey. It may not always be well to do this, but it does add to the harvest.

THE JOINT-SNAKE, AGAIN.

Willie Atchley has sent me another of these lizards. This one had never lost its tail, and was a beauty. In coming from Texas it took occasion to shed its scales, or skin. This was done in shreds, not entire, as seen in snakes. The specimen came in nice trim by mail, and delighted me. Judge of my regret, then, when a student, in studying its habits of motion, preparatory to giving a paper on this lizard before our Natural-History Society, let the latter crawl through a hole in the laboratory floor, and escape. The student felt even worse than I did.

SCALE LICE.

The scale lice, which secrete an abundance of honey-dew, and which Mr. Jos. Barrington, of St. Mary's, O., reports as infesting his lemon-trees, are closely allied if not identical with the one sent by Dr. Miller, which infested the English ivy. The genus is *Mytilarpsia*. It is near, if not *neri*. The plants should be treated with the kerosene emulsion, as I describe in Bulletin 58. This bulletin will be sent free to all who desire it, upon application.

Agricultural College, Mich.

A. J. Cook.

Friend C., if you have tested these two subjects, stimulative feeding and removing the queen, at the college apiary, as you people usually test disputed questions, I think we shall have to give up on both points. I am surprised to learn that your laboratory floor is so poor as to have a hole large enough for even a glass snake to creep through. My observation was to the effect that your buildings and rooms were models of perfection. I earnestly advise all our readers who are interested in this matter of fighting insect-enemies to send for Bulletin 58. But, dear friend Cook, you had better hire an extra clerk in anticipation of the calls that will be made for it. Remember

that we GLEANINGS people are now almost 10,000 strong.

SWARM-CATCHERS.

A NEW USE FOR THE DRONE-AND-QUEEN TRAP.

"We don't want swarms," says our friend Shuck. Well, we do not; that is, some bee-keepers do not. The bees do not seem to know this fact; or if they do, they care nothing about the wants of man. When the bees get ready to swarm, out they come, and so they will continue to do, no matter what we want, or what the breed, strain, or race of bees happens to be. We have *all* found this out, haven't we, Bro. Shuck? 'Tis well enough to talk about a non-swarming race or strain of bees; but it is quite another thing to produce them by any means yet devised.

Well, now, recognizing these facts, why not be ready for the bees when they get ready to swarm? Let us provide the easiest, cheapest, and most practicable means for catching swarms when they issue. When we first introduced the drone-and-queen trap, friend Root said a good word for it, and at the same time remarked, "Now if some one will devise some way for hiving bees when they swarm, etc." (I can not recall just the words, as I have not the copy of GLEANINGS at hand that contained the article), "it will be a good thing," or words to that effect. Well, what we are getting at now is friend Root's comments in a foot-note attached to the description of an article describing the self-hiver we were invited to send GLEANINGS about a month ago. What puzzles me is this: Why it was that, when Bro. Root indicated that a self-hiver would be a good thing when speaking of the trap, some six years since, is the fact that he did not know at that time all about self-hivers, as mentioned in the foot-note spoken of above. The idea of inviting some one to attempt to invent a self-hiver, and then comparing it, when invented and described, to Mr. Quinby's "queen-yard" arrangement! Goodness, friend R., it makes me nervous to think about it. Quinby's device was about as much like our automatic swarmer as cheese is like chalk.

FIG. 1. TRAP ATTACHED TO A HIVE.

Excuse us for getting off the track. We will now

describe how to catch a swarm of bees in the drone-and-queen trap.

Those who use the trap have noticed that, when a swarm issues, and after the bees return to the parent hive, as many pile into the trap as can, and will be found there. The idea struck me that the trap might be made large enough to hold the entire swarm, and so we show the reader a cut of such a trap, and will describe how it is arranged, and its workings in catching a swarm of bees when they issue.

Fig. 1 shows the trap attached to a Bay State hive. You will see that it projects considerably beyond the front of the hive. The bees, to gain access to their hive, must pass under the trap and enter through the metal, A.

Fig. 2 shows the interior of the catcher. It is the same as the drone-trap. In fact, it is nothing but the drone-and-queen trap on a larger scale. Instead of being made just large enough to hold a pint of bees the trap will hold the largest swarm likely to issue from any hive.

The trap has a portable cover (c), so that, when a swarm has been hived, the bees can be quickly removed, or placed in a new hive. This device may be attached to the hive in a dozen different ways, to suit the fancy of the apiarist. It will be seen that there is a stake (D) driven into the ground under the front end of the trap, for the box to rest on.

B, as shown in Fig. 2, is a box, open on one side, so the bees can enter, while the opposite side is covered with perforated metal. This represents the bottom chamber of the drone-and-queen trap. Two cone-tubes are used for the bees to pass into the trap.

We stake our reputation as a bee-keeper, on the statement that this trap will catch and hive ninety-nine out of every one hundred swarms that issue. The queen will enter the trap, and, when the bees return in search of her, they will readily find her ladyship in the box, ready to receive them.

You will notice in the trap (Fig. 2), and just ahead of the cone-tubes, a strip of perforated metal. This is so arranged that it comes exactly over the entrance to the hive, and above the metal A. When the bees return after having missed their queen, they will pass into the trap through this metal, and join their queen. Here the bees will be found on the return home of the apiarist, when they can be disposed of to suit his pleasure. If no hive is ready, the box can be placed on the stand the bees are to occupy, and hived when most convenient. If the bees are to be returned to the hive they issued from, this can be done after the combs have been examined and the queen-cells removed or destroyed.

We shall send Bro. Root one of these traps, and arrange with him to make some at once, so those who desire can test them the present season.

Wenham, Mass.

HENRY ALLEY.

Friend A., I think I understand your arrangement as given in Fig. 1; but if I am

correct it is a little confusing in Fig. 2, because the engraver has not quite done his duty. The hiving-box, and B and C, are simply three separate articles, and rest upon each other in the manner shown, only for convenience. I really hope the device will have 99 out of 100 swarms that issue. But without taking more space I think we had better wait for reports from those who are now using it to hive swarms. With the present crowd of business now upon us, we could not undertake to make any new thing just now; and as we have so little swarming, especially in connection with our selling bees by the pound, we fear we shall not be able to make a test of the machine that will be very satisfactory.

FRAME-SPACERS.

THICK TOP-BARS AND PERFORATED ZINC.

EVER since Dr. Miller and you were talking about that queen-excluding strip to go on the top of the heavy top-bars, I have been thinking; and this is what I have evolved: Instead of having a saw-kerf to slip the zinc into, which is almost sure to be glued up with propolis, bend the zinc into an L shape, and let the L part with the slots in slip down over two broad-headed nails driven into the side of the top-bar; then when a frame is to be removed, the zinc can be lifted out, and have the "lateral" movement, so desirable to the frame. They could all be taken off if necessary. Have I made my meaning clear? But I do not think any such arrangement will ever become practical, as it would be so much in the way in handling the frames.

If we are to dispense with honey-boards by using heavy top-bars, it seems we have got to have the frames spaced just exactly right; in fact, too exact for the average bee-man's eye to do the work; so, to help out, here I have invented what I call an automatic spacer, made thus, the points to be made of heavy tin, and to be just a bee-space at the base, and, say, one inch from base to point, and the distance between them to be just the width of the top-bars. Not to be left on the frames, but to crowd down from the top, so as to force the frames to the right place, two would be necessary; for if only one were used, the frames might move out of place at one end, while the other was being adjusted. They might be nailed to a block with a handle, something like your tool for fastening foundation in wired frames. If to be used to remain permanently on the frames, of course a $\frac{3}{8}$ block would have to be used. I think this might give the advantage of fixed ledges on the hive, with none of the disadvantages. What do you think?

C. A. HATCH.

Ithaca, Wis., Feb. 19.

Friend H., your slips of zinc would be stiffer and safer to handle by having a fold made lengthwise, as you suggest; but I agree with you that they would be too much machinery. I do believe that some sort of frame-spacer would be an excellent thing, if we propose to do away with burr-combs by reducing the space between the top-bars. Ernest suggests that a spacer could be made by driving wire staples into the strip of

FIG. 2. OUR NEW SELF-HIVER.

wood. The round end of the staples would readily force the frames into position. Of course, the staples need not project out of the wooden bar more than far enough to bring the frame into position. Our friends who are fond of extreme accuracy in their work would like such an arrangement.

On page 415 another friend gives us an excellent illustration of a frame-spacer. His intention was to use it to keep the frames in position. But they will answer nicely for bringing frames into place, as suggested by friend Hatch above.

HONEY STATISTICS

FROM ALL PARTS OF THE UNITED STATES.

In order to read understandingly the reports given below, it will be necessary to observe the following points: First, the State is given; then next in their order are the names of the reporters, with their respective postoffices. To indicate locality, the usual abbreviations are used—N., S., E., and W., for north, south, east, and west; N. E. for north-east, etc. The letter C indicates the word "central." E. C., east central, etc. In the following list, the first figure represents the month, and the second figure the date at which the report was rendered. The small letters, a, b, c, d, etc., indicate the answers to the questions propounded in questions a, b, c, etc., just below.

For some reason or other we have not received reports from all of our correspondents, although nearly two weeks have elapsed since the questions were sent out. The average date at which the replies are given is May 18. We propounded only two questions, and they are as follows:

a. *What percentage of loss did you sustain among your bees last winter, and by what method—indoor or outdoor?*

b. *As nearly as you can estimate, what was the percentage of loss in your locality, and by what method?*

ALABAMA.

J. M. Jenkins, Wetumpka. C. 5-19.
a, b, 10; out in the sun. Loss was caused by hard freeze March 1st, after a very warm winter.

W. P. W. Duke, Nettieborough. S. W. 5-20.
a, b, 2; outdoors.

ARIZONA.

Jno. L. Gregg, Tempe. C. 5-20.
a, 2; outdoors; b, 2; outdoors; all outdoors in this Territory. Have taken 3000 lbs. mesquite honey.

COLORADO.

Mark W. Moe, Denver. C. 5-17.
a, 4; bee-house; b, not over 5, mostly outdoors, no chaff.

CONNECTICUT.

Lewis Sperry, Hartford. 5-16.
a. Less than 10; outdoors; b. about ten per cent.
Daniel H. Johnson, Danielsonville. E. 5-16.
a, 10; outdoor; lack of stores; b, 10 to 20; outdoor, but all starved.

R. M. Wilbur, New Milford. 5-17.
No loss; 30 stocks; outdoors; 5 per cent; all outdoors.

GEORGIA.

Walter McWilliams, Griffin. W. C. 5-19.
a. None; outdoors; b. none; outdoors in Simplicity one-story, without enamel cloth.

T. E. Hanbury, Atlanta. N. 5-16.
a, b. No loss; outdoors. As a rule we have no loss in this section from wintering.

R. H. Campbell, Madison. 5-22.
a, 15; outdoors; b, 25; spring dwindling. It was summer till March, the next 60 days winter. Honey-crop a failure.

INDIANA.

Mrs. A. F. Proper, Portland. E. C. 5-19.
a, b. No loss. Outdoors.

I. R. Good, Vawter Park. N. W. 5-23.
a, 5%; cellar; rest, chaff; b, 6; outdoors in chaff.

ILLINOIS.

C. Dadant, Hamilton. N. W. 5-17.
a, 3 per cent, both ways; b, 10 or 15; out; starvation the cause. No loss anywhere except from overbreeding and subsequent starving.

F. W. Goodrich, Bloomington. C. 5-15.
a, 5; outdoors; b, 10; outdoors.

C. C. Miller, Marengo. N. 5-16.

a, 7 per cent indoor; b, 10 per cent, mixed. Bees booming; heavy in bees, but weather is cool, and bees may starve in June as last year.

Mrs. L. Harrison, Peoria. W. C. 5-17.

There has been no loss, indoor or out, except by starvation. Bees did well this spring, until the May freezes; since then bees have been chasing out the drones; some would have starved had they not been fed.

INDIAN TERRITORY.

R. W. Swain, Vinita. 5-17.

a, 1 had 25 stands; lost 1 from moth; outdoor; b, very little loss.

IOWA.

Z. T. Hawk, Audubon. W. C. 5-16.

a. Lost none; cellar; b, 12%; cellar, mostly. 1 have lost a few colonies by robbing since placing them out. All are short of stores.

Eugene Secor, Forest City. N. 5-20.

a, b, 10; cellar.

J. W. Bittenbender, Knoxville. S. E. 5-15.

a, 5; wintered in cave; b, 8; wintered outdoors; bees in good condition, but very dry; unless a rain comes soon, the honey-crop will be short.

Oliver Foster, Mt. Vernon. E. 5-17.

a, 30; indoors; 1 per cent outdoors; b, 10 indoors.

A. Christie, Smithland. W. 5-17.

a. About 2; part in cellar, part outdoors; chaff in upper story, over bees. b, 1 can not estimate, more than that loss is small.

KANSAS.

B. F. Uhl, Boling. 5-19.

a, No loss; outdoors; b, no loss; on summer stands.

J. B. Kline, Topeka. E. C. 5-16.

a. Part indoors and part out. No loss. b. None to speak of.

KENTUCKY.

D. F. Savage, Hopkinsville. S. W. 5-20.

a, 5; indoors; b, 5; outdoors. A few cases of spring dwindling.

J. P. Moore, Morgan. N. 5-16.

a, 9; outdoors; b, 25; outdoors.

MAINE.

J. Reynolds, Clinton. S. E. 5-19.

a, 0; cellar; b, 8; report says mostly loss of queens.

C. W. Costellow, Waterboro. S. W. 5-17.

a, 10; outdoors in single-wall, without protection. b, 5; all methods.

IDAHO.

Whitney Bros., Payette. 5-19.

No loss to speak of; bees get no care whatever; and, under circumstances, do well.

MARYLAND.

Simon P. Roddy, Mechanicstown. 5-18.

a, 0; outdoors, frame hives; b, 10; outdoors; box hives.

S. Valentine, Hagarstown. 5-21.

a, 5; outdoors; b, 25; starving out.

MASSACHUSETTS.

J. E. Pond, No. Attleboro. S. E. 5-19.

a. Saved all. Wintered outdoors. b. Probably 20, all outdoors. Few bees are kept within 25 miles of my residence. 100 colonies would cover the number, I think. I wintered only 5 colonies.

E. W. Lund, Baldwinville. N. C. 5-19.

a, b. No loss; in chaff hives. I wintered outdoors.

Wm. W. Cary, Colerain. N. W. 5-16.

a. None, only by queenlessness; cellar and six hives; b, 5 to 10; cellar and summer stands. Condition of bees never better at this season of year.

MICHIGAN.

R. L. Taylor, Lapeer. 5-17.

a, 5; cellar; b, 15; part outdoors, unprotected, and part in cellar.

George E. Hilton, Fremont. W. 5-17.

a, b, 5; chaff hives.

A. J. Cook, Lansing. C. 5-15.

a, 5; in cellar; starved; none outdoors; b, about 10; three-fourths cellar; one-fourth on summer stands.

James Heddon, Dowagiac. S. W. 5-16.

a, $\frac{1}{2}$ outdoors, no loss; $\frac{1}{2}$ indoors, 30 per cent loss. b. The same as above was practically true with all the bees in this locality.

H. D. Cutting, Clinton. S. E. 5-18.

a, 2 from 62 after setting out from cellar. Those packed out, no loss. b, 10 to 12; nearly all outdoors.

MINNESOTA.

W. Urie, Minneapolis. E. C. 5-20.

My own bees sustained a loss of 15 per cent in bee-house, made nearly frost-proof, built on top of the ground. The loss in this part of the State is fully 25 per cent. Almost all are wintered in cellars. I do not know of any parties who use the chaff hive.

N. P. Aspinwall, Harrison. C. 5-20.

a, $\frac{2}{3}$; cellar; b, 50; cellar; cause, honey-dew producing dysentery.

MISSOURI.

Jno. Nebel & Son, High Hill. E. C. 5-17.

a, 1; cellar; b, 5; outdoors.

James Parshall, Skidmore. N. W. 5-19.

a, 15; outdoors, in single hives; b, about 15; mostly by starvation.

Chas. L. Gough, Rock Spring. E. C. 5-19.

a, 24; outdoors; b, 50; outdoors.

E. M. Hayhurst, Kansas City. W. 5-17.

a, 0; cellar; b, 5; outdoors.

S. E. Miller, Bluffton. E. C. 5-18.
a. 17; winter and spring; outdoors; b. perhaps 20; chaff division-boards and cushion in S. hives.

NEBRASKA.

J. W. Porter, Ponca. N. E. 5-17.
a. 85; outdoor trench; b. 25; lack of stores.
F. Kingsley, Hebron. S. C. 5-21.
a. 0; outdoors; b. 5; outdoors, no packing.
J. M. Young, Plattsmouth. 5-19.
a. $\frac{1}{2}$ of our apiary is lost; all died in summer hives; but little loss in chaff hives; wintered on summer stands. b. $\frac{1}{2}$ of the bees in general are dead, all caused from starvation. The wintering on summer stands is practiced more than any other method, and without chaff.

NEVADA.

E. A. Moore, Reno. W. C. 5-22.
a. 5; outdoors; all my hives are Simplicity. b. 25; outdoors; mostly in old box hives. The winter was the coldest we have had for 30 years, to my knowledge. Bees are doing splendid at present time.

NEW HAMPSHIRE.

C. E. Watts, Rumney. C. 5-19.
a. 66; cellar too cold; b. 15 to 20. I think nearly all in cellar.
L. A. Freeman, Lancaster. N. W. 5-18.
a. 30; cellar; b. 35 indoors. Cause, dysentery. I never heard such universal complaint.

NEW JERSEY.

Watson Allen, Bernardsville. N. C. 5-19.
a. 6%; outdoors, in chaff hives; b. 10; outdoors, in single-wall hives.

J. D. Coles, Woodstown. S. W. 5-19.
a. 28; chaff; b. 40; outdoors, old-style gum.

NEW YORK.

G. M. Doolittle, Borodino. C. 5-17.
a. 25; part in cellar, part outdoors; b. 25; same as above, cause, honey-dew.
H. P. Langdon, East Constable. N. E. 5-19.
a. 12; cellar; b. 25; cellar.
G. H. Knickerbocker, Pine Plains. 5-17.
a. 5; in cellar; no loss in those wintered outside. b. 10, mostly outdoors.

NORTH CAROLINA.

Abbott L. Swinson, Goldsboro. E. 5-20.
a. 10; open air; b. 50; open air.

OHIO.

A. B. Mason, Aburndale. N. W. 5-17.
a. 3; starved; cellar; b. 5; outdoors and in cellar.
Chas. F. Muth, Cincinnati. S. W. 5-16.
Lost none; but 3 colonies had lost their queens; outdoors; b. perhaps 20; mostly in single-walled hives.
S. A. Dyke, Pomeroy. O. 5-17.
a. 20; outdoors, in chaff mostly. b. 10; outdoors. My loss was caused by dividing too late.
Dr. G. L. Tinker, New Philadelphia. N. E. 5-16.
a. No loss. All outdoors, in winter cases. b. 3; starvation; wintered in chaff and single hives.
Dr. H. Besse, Delaware. C. 5-20.
a. 10 cellar, and 15 by spring dwindling; b. about 20 to 30, as nearly as I can learn, mostly from springing; too much cold rain during time of bloom.

PENNSYLVANIA.

S. W. Morrison, Oxford. S. E. 5-17.
a. No loss; outdoors; b. 40; box hives, summer stands. Prospect for a big crop of honey excellent; too much rain, the only thing that can prevent.
Thos. C. Davis, Pittsburgh. C. 5-19.
a. No loss, except three queens, out of 34; outdoors in chaff; b. heard of no losses except a few queens, outdoors.
C. W. King, Emlenton. N. W. 5-20.
a. 100; b. 98; outdoors.

RHODE ISLAND.

A. C. Miller, Providence. E. 5-17.
a. None; outdoors; chaff, unpacked; b. 30 to 40. All by starvation.
Samuel Cushman, Pawtucket. 5-15.
a. Mine, 5; few in cellar. b. Box hive fared badly. Loss from starvation throughout the State, probably 50 or 60.

SOUTH CAROLINA.

H. T. Cook, Greenville. 5-18.
a. 4; b. light.
W. J. Ellison, Stateburg. C. 5-21.
a. 3; starvation; outdoors; b. I don't know.
J. D. Fooshe, Coronaca. 5-17.
a. No loss; outdoors; b. none; Simplicity and box hives.

TENNESSEE.

W. H. Greer, Paris. N. W. 5-19.
a. b. 25; outdoors.
C. C. Vaughn, Columbia. C. 5-20.
a. 2; outdoors; b. 8; outdoors; no packing, thin hives.
Gaston B. Cartmell, Jackson. W. 5-19.
a. I had 45 stands; lost 2; b. outdoors, without protection.

TEXAS.

J. P. Caldwell, San Marcos. S. W. 5-18.
a. None; outdoors, in S. hives. b. 5.
L. Stachelhausen, Selma. S. C. 5-18.
a. 2 by queenlessness; outdoors. b. 2. We have no winter losses here except by queen losses or starvation.
J. E. Lay, Hallettsville. S. W. 5-21.
No winter losses here.

VERMONT.

A. E. Manum, Bristol. W. 5-19.
a. 3 winter and 3 in spring, making 6 in all; outdoors, chaff. b. 30; outdoors in chaff.

J. E. Crane, Middlebury. W. 5-15.

a. 33; cellar, 75; outdoors in chaff hives. b. About 30; wintered mostly outdoors in chaff hives. Cause of loss, gathering a large amount of honey-dew last year.

H. E. Harrington, Walden. 5-19.
a. 0, in sawdust; 25 without sawdust; cellar; average, 15. b. 20; cellar.

Howard J. Smith, Richford. N. C. 5-17.
a. 0; cellar; b. 25, outdoors. Cold wet weather.

F. M. Wright, Enosburgh. E. 5-17.
a. 5; cellar; b. 10; cellar.

VIRGINIA.

H. W. Bass, Front Royal. N. 5-17.
a. 3; outdoors. b. 5; outdoors.

WEST VIRGINIA.

J. A. Buchanan, Holliday's Cove. N. 5-20.
a. 2; outdoors; b. 5; outdoors. Loss from starvation will be great within the next ten days, unless feeding is attended to, as no honey has been gathered.

Will Thatcher, Martinsburg. W. C. 5-17.
a. One colony out of 60; a pure case of starvation; outdoors; from 3 to 4 inches timothy chaff in burlap cushions over brood-chamber. b. With proper care, no loss.

Jno. C. Capehart, St. Albans. S. W. 5-19.
a. 0; outdoors; b. no other modern bee-keepers in my locality.

M. A. Kelley, Milton. S. W. 5-17.
a. 7; outdoors; b. about 10; all outdoors. No chaff hives used.

WISCONSIN.

Joshua Bull, Seymour. E. 5-19.
a. 35, cellar; 19, outdoors in chaff; loss mostly from spring dwindling; b. 30 to 50; cellar and clamp. One bee-keeper lost all of his bees. Cold backward spring, unfavorable for bees to build up.

S. I. Freeborn, Ithaca. S. W. 5-19.
a. 25; cellar; b. 25; mostly cellar wintering.

Frank McNay, Mauston. C. 5-16.
a. 25; indoors; b. 25; indoors.

E. E. Tongue, Hillsboro. 5-19.
I wintered mine on summer stands in L. hive, no loss. I haven't found any loss last winter; all good; all winter in cellar.

E. France, Platteville. S. W. 5-17.
a. 6; outdoors in chaff; b. 10; outdoors.

A summarized statement is as follows: The average percentage of loss among the special reporters during the past winter is only 8 $\frac{1}{2}$ per cent. By referring to the statistics of a year ago, we find that the loss was 9 per cent. We expected to see a smaller percentage for this year. The only losses, with few exceptions, that occurred during last winter, of any account, were from overbreeding and consequent starvation. If we eliminate this cause of mortality, the percentage will probably be very low. The average loss in the vicinity of the reporters, we find to be 14 $\frac{1}{2}$ per cent. Last year at this time it was 17 per cent.

Perhaps it will be interesting, right here, to compare the average losses of the three preceding winters, since we began the department of statistics. The special reporters' loss during the winter of 1887 was 16 per cent; during 1888, 9 per cent; during the winter of 1889, 8 $\frac{1}{2}$ per cent. The locality losses for the winter of 1887 were 33 per cent; for 1888, 17 per cent; 1889, 14 $\frac{1}{2}$ per cent. It is to the credit of the books, periodicals, and progressive apiculture, that the winter losses have been decreasing. Although the reports do not show it, we notice by correspondence that there has been a very heavy loss in the region of Gallupville, N. Y., many bee-keepers losing all their bees. The cause is attributable to honey-dew. One bee-keeper said his Italians, because they gathered nothing but white stores, wintered beautifully, while his blacks and hybrids, having gathered a lot of honey-dew and buckwheat, almost all died—a great score for Italians, because they will get white stores if there is any possibility of doing so. We also gather from correspondence that there have been quite heavy losses in certain parts of Minnesota.

TREATING DISEASE WITHOUT MEDICINE.

A REVIVAL OF ONE LINE OF THE OLD WATER CURE.

I SINCERELY hope that my friends of the medical fraternity will not think that I am trespassing on their domain; in fact, I look for and beg their assistance and indorsement, that we may fight down frauds and swindles as a common enemy to mankind. Almost everybody knows more or less about the water-cure that made such a stir in regard to the treatment of disease perhaps 35 or 40 years ago. Water-cure establishments were plentiful in almost every locality then, and people went about to give lectures, and proposed to cure all diseases by water alone. Pure water was called the obvious natural remedy furnished by the great Creator to his creatures; and, like the advocates of electricity a little later, they loudly claimed that it was all-sufficient for every disease that flesh is heir to. Some of us smile now as we remember how these things had their day, and finally passed away. Water cure, however, has not entirely passed away. When you send for your family physician, nine times out of ten he will call for some hot water—a dipperful, a pailful, or perhaps a tubful; and if you just look back you will remember that the patient usually got better right away, when the physician decided that the water was what was needed. I once fell from a building and hurt my ankle. The pain was so intense that I groaned aloud (if it had been a woman, perhaps she would have kept still; you know how it is when a man is in pain). A doctor was soon procured, and I begged him to give me something—brandy or chloroform. He said he guessed all I needed was a little hot water. He put his hand into it, and said he guessed that would do, and told me to put my foot in it, even if it did come pretty near scalding. I thought at first I could not bear the water because it was so hot; but finally I got it down so the water covered the swollen ankle. The pain eased up as if by magic, and I have oftentimes wondered if it were possible that so simple a remedy could do so much. When you are so tired and worn out that you feel as if you could hardly put one step before the other, a bath in pretty hot water will set you up bright and vigorous. You are perhaps all well aware of this. A great many times we suffer because of the lack of *soap* and water. Perhaps some of you would resent such a charge; but, hold on a little. A woman was once deaf, and had been so for years. A traveling lecturer on physiology, by means of soap and water, and a proper syringe, washed out the accumulations of the ear so that she heard again as well as she ever did. This was accomplished in less than an hour. Water applied in the proper way sometimes performs wondrous cures in washing out the accumulations between the nostril and the ear. We all know what water will do for the feet when sore, or when treating them for corns. At some of our sanitariums they give relief by bathing, accompanied by rubbing and kneading the

body. One of the most prominent physicians of the United States has of late accomplished great things by giving his patients hot water to drink. You may smile at this. Why should anybody need a doctor to administer drinks of hot water? Well, I do not know. They claim to have received great relief from swallowing hot water in large quantities. And now we come to the point that has prompted this article.

If water performs such wondrous cures externally, or when introduced into the ear and nostril, or other organs of the body, why may not great benefit accrue from a thorough washing and cleansing of the digestive apparatus? When you come to think of it, I presume you will be ready to say at once, "Why, sure enough!" and I believe that is just what our physicians have been doing more or less for ages past. Have you ever felt, my friend, as if you would give a good sum of money to be able to wash out your "insides" as thoroughly as you can your "outsides"? I have felt just that way a good many times, and have thought of the method in common use for doing it; yet it seemed to be a good deal of a medical operation, and I always supposed it must be done by the aid and advice of a physician. When we want to cleanse a jug we can cleanse the outside very easily, because it is in plain sight. If we want to cleanse the inside, however, the best we can do is to put in some water, and shake it about thoroughly. This we can keep doing until the water we pour out is as clean as when it was put in. Then we pronounce the jug clean. If we want to clean a barrel, we do the same thing; and by giving a barrel a vigorous tumbling about, we can secure a pretty thorough rinsing; and this is what Dr. Hall claims as his great discovery; and yet it is not a discovery, nor is it new at all. See the following, which I copy from the first doctor book I pick up:

"Water about blood-warm should be used when the purpose is to relieve constipation, and a considerable quantity—one to three pints, or more—may be used. The water should be retained for a few minutes, while the bowels are kneaded and shaken."

The kneading and rubbing of the body amounts to exactly the same thing as shaking the jug or barrel, that the hot water may effectually dissolve away all accumulations.

And, by the way, I think I will copy the entire paragraph on this subject. It comes from Dr. Kellogg's "Rational Medicine," under the head of "Rational Remedies for Disease." More than 100 pages are devoted to the use of water in the treatment of disease. We have eye-baths, ear-baths, sitz-baths, foot-baths, wet sheet, vapor bath, etc. Here is the paragraph in question:

ENEMA.

Fecal accumulations in the lower bowel are more quickly and easily removed by an enema of warm water than by any purgative, laxative, or cathartic ever discovered or invented; and the use of this remedy is never accompanied with the unpleasant and painful griping and tenesmus which often accompany the use of cathartics. The administration is a trifle more troublesome, but the results are enough superior to more than repay the inconvenience. The syphon syringe is far preferable to

any other for administering injections. Water about blood-warm should be used when the purpose is to relieve constipation, and a considerable quantity—one to three pints, or more—may be used. The water should be retained for a few minutes, while the bowels are kneaded and shaken. If there is difficulty in retaining the water, a folded napkin should be pressed against the anus. In hemorrhage and inflammation of the lower bowel, cool or cold clysters should be employed, and should be retained as long as possible. The copious cool enema is a valuable antiphlogistic remedy used in conjunction with the cool bath in cases of violent febrile excitement, as typhoid fever, when temperature rises above 103° F. Large enemata of water, or of water containing quassia, are the best mode of treatment of ascariides, or the so-called seat worms.

Large, or what are termed forced, enemata are also recommended by Dr. Mosler as the most successful means of relieving intussusception. They are also recommended in hernia and in the treatment of tape-worm, in connection with other anthelmintics. In catarrh and other diseases of the large intestines they are useful in cleansing and washing away acrid secretions and foreign matters as well as in applying local treatment. A. Rohrbick, of Vienna, has observed that injections of water into the colon increase the fluidity of the bile secreted by the liver. This fact has led to its employment in jaundice due to catarrh of the biliary ducts as well as to other causes, and, according to Dr. Mosler, with successful results. In administering a forced injection, the syphon syringe should be employed. The patient should lie on his back with his hips elevated, and the enema should be administered slowly. When colicky pains occur, the injection should be withheld for a few minutes, until the pain subsides. When it is desired to force fluid into the small intestine, which may be done in case of necessity, the patient should be placed on his knees and shoulders, so as to lift the pelvis as much as possible, and the fluid should be introduced slowly.

Now, please notice, friends, when you pay money for a recipe or secret, the seller, as a matter of course, gives all the *advantages* of the great discovery, and puts it in the most glowing terms, while he entirely ignores its drawbacks or dangers; at least, such has been my experience. Printed circulars, scattered far and wide, from Dr. A. Wilford Hall, illustrates this very pointedly. Now, please read the following from p. 664, Dr. Kellogg's book:

But the enema may become a source of mischief if abused. If habitually relied upon to secure a movement of the bowels for a long time, the bowels lose their activity, and the most obstinate constipation sometimes results, precisely as from the prolonged use of purgatives.

Dr. Kellogg declares that this very matter of thoroughly washing or rinsing these organs *may be* a means of mischief. I understand that physicians do not all agree in regard to this. While some say the use of water internally will do no more harm than washing the hands and face daily, others agree with Dr. Kellogg. A good many of us would be very glad indeed if nature would at certain times forbear a little, and, if the use of water would induce her to get over a little of her "activity," what harm would it do to use it?

Dr. Hall also makes quite a point of his treatment for diarrhea, giving the idea to the reader that this is a part of his discovery.

Now let us see what Dr. Kellogg says under the head of "Diarrhea," after giving directions in regard to diet, on page 907 of "Rational Medicine." He writes:

Next in importance as a measure of treatment, is the proper employment of enemata. We have seen more benefit derived from the injection of large

quantities of hot water—as hot as could be borne, and in as large quantities as could be retained—than from any other single measure of treatment.

After reading the above I was greatly surprised to find I could bear water internally so hot as to be painful to my hand, without any inconvenience whatever; and this very warm or hot water seemed to give wonderful relief. In fact, the effect is very much like that of the rested feeling that comes from taking a pretty hot *external* bath. I am satisfied, too, that these *large quantities* of hot water do remove accumulations that may have been productive of harm for months, or may be *even years*. We read on the same page:

The hot or cold water used in injections should be employed in considerable quantities, either as hot as can be borne or quite cool.

From personal experience I am pretty well satisfied that no harm can come from using any excess of hot water, even if the quantity be so great as to produce a momentary sensation of sea-sickness.

There is much more in the book mentioned, on this subject; but the above, in connection with the advice of your physician, will be sufficient. And finally, dear friends, do not think of sending \$4.00 to anybody for some one's *secret* discovery, when your own family physician knows all about it, and has known so for years. Your family physician will also be glad to tell you all that is known in regard to it. There are a great many good physicians among the readers of GLEANINGS, and I appeal to them whether I am not right. Very likely, good will result from calling the attention of the world at large to this special line of water-cure treatment. We can not very well make a mistake in keeping ourselves *too* clean.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

That art on which a thousand millions of men are dependent for their sustenance, and two hundred millions of men expend their daily toil, must be the most important of all—the parent and precursor of all other arts. In every country, then, and at every period, the investigation of the principles on which the rational practice of this art is founded ought to have commanded the principal attention of the greatest minds.

JAMES F. W. JOHNSTON.

WHAT SHALL WE DO WHEN THE GROUND IS ALL THE WHILE TOO WET TO PLANT?

TO-DAY, May 24, almost nothing of our main crops is in the ground, because of heavy and incessant rain. For two seasons past we have had a similar experience, and were therefore partly prepared for it. We have had some sad experience in trying to work ground when it was too wet, and had therefore decided to have it in proper order, no matter how long it took. But here it is, almost June 1, and only one planting of corn has been made. Our first potatoes are pretty nearly knee-high, and so are some of the weeds. By watching our chances we have cultivated them up a few times; but if any portion of the weeds is left on top of the ground, they start to grow again. What cultivating we have done has been done when the ground was too wet for the horses to step on. A week ago to-day, by

working men, boys, and teams, until after sundown, we got in most of our early potatoes. The ground was so wet then that our teamster protested all day. Ever since then the ground has been almost like a swamp. The underdrains and overdrains are doing their duty, but they are not adequate. The only thing that can be worked is our plant-beds, six feet wide, and raised a foot or more above the paths by means of boards up at the sides. These plant-beds are worked without stepping on the soil at all, and, of course, it is all hand-worked; but the ground is manured and made soft with peat and sand, so it is so light and soft the garden-rake will give it all the cultivation needed. Just now I am seriously contemplating half an acre raised up in this way, to be worked entirely by hand. The only trouble is, during severe drouths it is hard to keep them wet enough so they do not dry clear through from side to side. Several times during the past week the ground would do pretty well for planting by hand, but it would not do for a horse to step on it. I presume that the great quantity of manure we have worked into it helps to hold the water. We first cover the ground with all the manure we can plow in; then we cover it again with a manure-spreader, and work this in with a cut away harrow. By the way, the cut away is the most useful tool for working manure into the ground I ever saw. When all other harrows would clog up and scrape the manure into heaps, the cut-away just chopped the manure and soil all up together, and turned it under in a way that could not help make any cultivator of the soil smile. Well, as I was saying, there have been several times during the past week when we could have planted by hand were the ground only marked. At half-past four this morning, the teams could have got along very well; but none of our men were up, and the horses had not been fed, or I should have got at it. By the time they were fed and ready, another drenching rain closed the business for the day, and today is Saturday. Garden-stuff already commands tremendous prices, just because of this continued wet weather; and I suppose that those who have any stuff to sell will have their own price. But how can it be done unless we make our gardens in raised beds, as I have mentioned, and substitute hand work for horse power?

To-day I have been considering putting in some things by stretching a string. As a rule, this does not pay, for we not only have the labor of moving the string at each row, but the digging must all be done by hand. The furrower and marker, drawn by a team of horses, is by all odds the cheapest and best, even for small patches of ground; and for setting cabbage and celery plants, the fine dirt thrown up by the furrower is just what is wanted to put back around the plant. For tomatoes, melons, squashes, and cucumbers, or any thing that is to be put from 6 to 9 feet apart, the labor of using the string would not be so great; and if we can, by the use of it, secure a crop when nobody else has any, it might pay exceedingly well. One objection to using a string, however, is

the tramping on the ground, necessitated by boys running back and forth to move the string, as well as in transplanting the plants. I am getting every year more and more averse to tramping over the ground—not only by the horses, but by men and boys, especially after it is worked up to a very high degree of fertility. Raised beds 6 feet wide seems to be the most feasible plan; and I feel sure these will pay for many products. They could be cropped very closely, and the ground kept so light and mellow that cultivation could be done very quickly and thoroughly by using rakes of different widths.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 161.—*Jones and Brown have been keeping bees on shares. Jones is the owner, and Brown is the apiarist. They agree to share equally in the profits and in the expenses. During the following winter three-fourths of the bees die. Jones avers that they were lost through carelessness on the part of Brown, and that he (Brown) ought to stand half the loss. Brown denies lack of attention, and says that, as the bees belonged to Jones, and no provision was made in the contract for such an emergency, the owner (Jones) must stand the loss. Both parties, however, agree to abide by the decision of a majority of the respondents to the Question-Box. Gentlemen, your advice is eagerly sought.*

Let him who loses no bees cast the first stone at Brown.

New York. C.

P. H. ELWOOD.

Ordinarily a share in the profits would imply a share in the losses, there being no provision to the contrary.

Illinois. N. W. C.

MRS. L. HARRISON.

Under the given state of facts, each must stand half the loss, even if not occasioned by the carelessness of Brown.

Wisconsin. S. W.

GEO. GRIMM.

I say Jones, providing the bees were well cared for, unless they agree, as would seem to me to be wise, to share it equally.

Michigan. C.

A. J. COOK.

If the above is a true statement of the case, Jones must stand the loss. Such has been my experience, and I never knew an agreement to the contrary.

Ohio. N. W.

A. B. MASON.

Don't keep bees on shares. There is always a chance for injured feelings. Better buy a few colonies, then Brown will surely be interested in their welfare, for they are his own.

New York. C.

G. M. DOOLITTLE.

If through the carelessness of Brown, he should share the loss, otherwise it is Jones's loss. If bees were insurable, and Jones had had them insured, would he give half the insurance money to Brown? On the other hand, if the insurance company thought the loss was through carelessness, they would not pay the loss.

Louisiana. E. C.

P. L. VIALON.

If Brown tended to the bees to the best of his ability, then they were Jones's bees that died, and Jones will have to stand the loss. The following spring they will commence the season with the bees they had left from the previous year, if they agree to keep on.

Ohio. S. W.

C. F. MUTH.

Such a question is very difficult to solve, especially as no evidence is given as to the locality where the bees are kept; yet if there are, not far from the apiary of Jones, some competent bee-keepers whose winter losses were much smaller than those experienced under the management of Brown, it would seem that the increase of loss was due to his carelessness or lack of experience, and that he ought to stand at least half of the loss.

Illinois. N. W.

DADANT & SON.

Unless gross carelessness on the part of the apiarist can be shown, the owner should stand the loss. Bees are precarious property. If the owner himself, or any other man, had taken care of the bees in this case, the result might have been the same. Although my losses in winter are usually small—less than 10%—I would not keep bees on shares for any man on ordinary terms, and agree to stand half the loss, or quarter of the loss, in wintering. I should consider the risk too great.

Illinois. N. C.

J. A. GREEN.

Jones, as a bee-keeper, undoubtedly knew the liability to loss in wintering, yet he makes no provisions to meet it in his contract. It is presumed that Brown was under obligations to use reasonable care on his part. Unless the loss was clearly the result of gross neglect, unreasonable and inexcusable in Brown, I can not see why Jones should have any claim upon him for the loss. But if Brown permitted this loss when he could have averted it by care or labor on his part, he ought, in justice, to have a share of it.

Ohio. N. W.

H. R. BOARDMAN.

If I understand the matter, Brown would stand all the loss if the bees were struck by lightning and all burnt up. So Jones is not to share in any losses. If, however, Brown is culpably careless, he must pay for the resulting damage; not sharing the loss, but paying all the damage. If the loss is partly Jones's fault he should pay for that part of the damage which results from his carelessness. It will probably be a difficult matter at best to decide just how far the loss has resulted from carelessness, and I counsel that each man be willing to do a little better than is right to his neighbor.

Illinois. N.

C. C. MILLER.

Not knowing more about the matter, it is impossible to decide. I have an idea you are both to blame for the loss. Brown may have taken away too much honey and left the bees to starve in the winter. In that case Brown should stand his own half of the loss; then as Jones is the owner of the bees, it is fair to suppose he had had more experience than Brown, and should have known the condition of the bees in the fall, and advised Brown what to do. If I had seen the bees in the spring after the loss, I could then give an opinion; but without any evidence whatever as to the cause of the loss, I can not decide.

Wisconsin. S. W.

E. FRANCE.

To decide this matter between Jones and Brown, I guess we shall have to have them before us to show or prove contract, for on the contract the matter rests. Ordinarily, in such partnerships the party owning the bees will have to take his chances on hard winters and poor honey-seasons; but he has a right to demand good and timely attention on the part of his tenant. If Brown properly cared for the bees, and they perished through some peculiarity of the season, Jones can not reasonably claim their loss as a part of the expense. On the other hand, were they lost through carelessness or improper handling at the hands of Brown, Brown should stand the loss resulting from his mismanagement.

Wisconsin. S. W.

S. I. FREEBORN.

I should say that Jones was the loser, as no provision is made in the contract to cover such a loss. Jones, it seems, is to furnish bees, and Brown to do the work; and as there seems to be no willful neglect or want of care on the part of Brown in caring for the bees, Jones must stand the loss. I have one apiary let out in this way for five years. At the start I furnished 148 colonies, but I did not agree to furnish more if they died, neither did my man agree to keep the number good. In three years the bees dwindled down to 28 colonies. I did not ask the man to make the 148 good. I let him the apiary with full confidence in his ability to manage it. If he was not competent, I simply misjudged, and I must stand the loss; but bees sometimes die with the best of management.

Vermont. N. W.

A. E. MANUM.

As no contract was entered into about the losses, it follows that neither can claim pay for loss of any thing belonging to him, unless unquestionably caused by the gross carelessness or criminality of the other. This is a general rule covering all kinds of property owned by either. It is implied, if not expressed in all such contracts, that the apiarist shall use due diligence and care with the other's property; but the burden of proof is on the owner. As there is a simple claim of carelessness on one side and of denial on the other, it looks to me as though Jones will have to stand the loss. My Iowa apiary of about 150 colonies is rented on somewhat similar terms, and we sustained quite a loss two winters ago; but I never contemplated making any claim for the same, except that new colonies next year were all mine until the original number was again secured.

Cuba.

O. O. POPPLETON.

Well, well! We are now in a responsible position, but we will not shirk the responsibility. The questioner seems to admit, that, had Brown given proper attention to the bees, the loss was to rest with Jones, which is usually the case where bees are taken on shares. Now, then, a question arises, and a dispute between Brown and Jones, as to proper attention being given the bees. Now, if Jones has a claim against Brown because of malpractice, as professor of apiculture, it seems to me that it has nothing to do with the contract whatever. He should sue him for damages; but it is a separate deal altogether, as we see it. The division of the honey should be made, and probably has been made, and the question of the loss of the bees from malpractice is a different thing. If the bees died from starvation, I should think Jones would not

have much trouble in proving a claim, provided he knew nothing of the condition of the bees when they went into winter quarters, or was deceived in regard to it. But, on the other hand, if the bees did not die of starvation the chances are 999 out of 1000 that no malpractice on the part of Brown can be shown.

Michigan. C.

JAMES HEDDON.

At first the Rambler was inclined to say that Brown should stand all the loss, just to punish him for doing such a thing as to take bees on shares. But we think he has already received punishment in worry over the matter, so that he will never take any more bees on shares—eh, Brown? The Rambler would, however, say that, as there was no provision for such an emergency, and as Jones knew that such an emergency was liable to arise, we think that on Jones rests the most of the blame. As to the plea of carelessness, it seems that Jones just found out that point after the bees died. If Brown lost the bees through carelessness, then he must be careless upon other points, and must be well known as a careless man. Knowing this, why did Jones let his bees to Brown upon such loose terms? The Rambler would say that Jones must stand the loss.

New York. E.

RAMBLER.

I understand by the contract, that Jones's capital with the ordinary risks of deterioration in value of the same, is to balance Brown's skill and labor. I should think that loss from unavoidable causes should be at Jones's expense; all losses by Brown's mismanagement or neglect should be at Brown's expense. But without a knowledge of the cause of the death of the bees, I have nothing to base a decision on, which decision must rest on the facts of the cause of death. If the bees did not make honey enough during the season to keep them over, it should be the owner's loss. If they starved because the honey was taken from them, the apiarist should be the loser. If the bees died of dysentery or spring dwindling, I would exonerate the apiarist from almost all the loss, as, in my experience in wintering in Ohio and Iowa, I lost several apiaries almost entirely, with the best care I could give them. I think this is probably a case that would test two of the best men in the country to bear and forbear sufficiently to leave good feelings between both parties. It interests me to see them so generous as to leave the matter to disinterested and presumably intelligent bee-keepers.

California. S. W.

R. WILKIN.

Ah, here we are, a duly constituted court of equity. Looks as though we should need some depositions—and how about the fees? Assuming that the contract was for but one season, three cases arise: 1. Bees lost clearly without blame on Brown's part. 2. Bees lost, and the real cause of their dying doubtful. 3. Bees lost plainly by Brown's misdoing or neglect. If the evidence puts the matter as case 1, Brown, of course, goes clear. If the evidence puts the matter as case 2, I vote that Brown go clear. Most bees that die in winter (and they are myriads) die from causes not very clearly understood; and to hold the luckless wight who handled them last responsible is plainly absurd and unjust. As the case is stated to us, the indications are that this case 2 covers the matter. If the evidence puts the matter as case 3, I vote that investigation be made whether Jones might

not have saved his bees by a little inquiry as to their condition, such as he would naturally have made had they been sheep or pigs. I hold, that absurd and total indifference on his part should bar him from recovering of another man but little more guilty than himself. If the matter lies in case 3, and Jones has not shown culpable indifference to his own property, then I vote that Brown be held responsible to the following extent: He shall have the option of making good half the loss, or of taking a number of colonies of bees equal to the survivors, and building them up to an apiary equal to the one lost. If he chooses the latter he shall bear all expense and labor, and turn over all income, if any, to Jones.

Ohio. N. W.

E. E. HASTY.

Well, well, well! what an array of legal lore! When I began reading, I ran down the column to see how many lawyers we had on the list. Our friend George Grimm is the only one I recognize as such, and he says very briefly that the loss should be divided, as Prof. Cook suggests also, at the top of the list; and our good friend Wilkin winds up by an exhortation for each one of them to show forth the spirit of "in honor preferring one another." At the same time, however, there is a little bit of sarcasm in the closing sentence. I believe that, if I were so foolish as to go into the partnership business in keeping bees, as soon as I found myself in such a dilemma I would make haste to outdo my partner in generosity, even if it took more than the bees were worth, and then I would resolve to buy outright, when I wanted any such property in the future.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

A SIMPLE WAY OF CONVERTING FRAMES ALREADY IN USE INTO HOFFMAN FRAMES.

In GLEANINGS, May 1, pp. 330 and 331, you illustrate and describe a plan by which the Hoffman frame can be simplified, and advise bee-keepers not to go too fast. As soon as I read it I thought of this plan, which I believe will just suit me exactly. I take $\frac{3}{8}$ stuff and cut it into strips as wide as the end-bar is thick, and 4 inches long, and nail them on the upper end of the end bar, as represented in the inclosed drawing. A is the top-bar; B is the end-bar of a Langstroth frame. I use the Langstroth frame, top-bar one inch wide, and, after reading your foot-notes, I had 10 frames fixed up before supper. There may be some objections to this style, but they need not cost much on my plan. In hiving swarms they must certainly be real handy.

JOSEPH MASON.

Wallace, Ill., May 12, 1890.

Your suggestion is capital, friend M. I do not know why I did not think of it before.

Yes, those of us who would like to test the Hoffman frame can easily do so by making a very slight change, in the manner you suggest, in the frames we already have in use. I hope that quite a number of our readers will try a few frames, and report. If they are not a success, the sooner we know it the better.

A PROJECTING TOP-BAR.

You ask for suggestions for spacer for frames. Make them like the top or bottom of sections. Cut out at the ends—at dotted lines if you want to. No staples, no nothing; a little more wood, that is all.

Perhaps you have thought of this a thousand times, as it is so simple. Perhaps it is like many other things—no good at all, and just a waste of postage to send it to you.—There is much good in GLEANINGS, even for those who do not keep bees.

Krumroy, O.

C. H. WELCH.

Yes, this sort of top-bar has been before suggested. The trouble with it evidently was, that the projections would not readily slide by each other. The modified Hoffman frame (see page 330) would be better, I think.

E. R.

SPRAYING FRUIT-TREES IN FULL BLOOM; IS THERE ANY LAW AGAINST, TO PROTECT BEE-KEEPERS?

I write to you to make the inquiry if there is any law in Ohio to protect the bee-keeper against the danger of spraying fruit-trees with poison when in full bloom. There is a neighbor here who has bought a "Perfection" pump to spray fruit-trees, and he says that it was recommended to him to spray in full bloom. If this is the case I think the manufacturers should be informed better. I had him read your article in April 1st GLEANINGS, and also the inclosed, from Chagrin Falls *Exponent*. Please reply in GLEANINGS.

Ford, O., May 19.

HENRY BOSWORTH.

The following is the clipping referred to:

Prof. Reefey, editor of the *Elyria Democrat*, who is good authority on such matters, has the following in his paper relative to spraying fruit-trees.

The codling moth and other insects have become so numerous in this locality that it is impossible to raise apples or other fruit that is not more or less injured by these pests. No good farmer thinks of raising a good crop of potatoes without using Paris green or London purple on the vines, to destroy the beetles.

Mix one-fourth of a pound of London purple with forty gallons of water, and spray the trees soon after the bloom drops off, when the apples are about the size of peas. Should a washing rain follow soon after, the spraying should be repeated.

Paris green may be used in the same proportion, but it is more liable to injure the trees. In either case, the poison should be well mixed by stirring.

Let a number of farmers in a neighborhood buy a force pump and hose, with spraying nozzle, and mount it on a frame on a wagon so that a barrel with the solution can be placed under it. There are force pumps in the market especially adapted to this purpose.

For spraying on a small scale, a hand pump and a bucket are sufficient. A small hand pump will cost about a dollar.

Remember that the solution is a poison, and must be carefully handled, and don't let your stock feed on the grass under the trees shortly after spraying.

Finally, experience has proved that it pays to spray apple, pear, plum, and cherry trees, and that it is perfectly safe to do so.

Friend B., there is no special law that will touch the matter you mention; yet there are very plain laws forbidding one neighbor to poison the stock belonging to another; and I am pretty certain that one has no right to poison even trespassing stock. In this case it can be proven, I think, that there is no need at all of spraying the blossoms while the bees are at work. Will some of our bee-keeping lawyers enlighten us a little? If the matter is going to be complicated, perhaps we had better leave it with the Bee-keepers' Union.

WIRING FRAMES WITH FOULTRY NETTING.

In GLEANINGS, May 1, there is quite a discussion about the proper mode of wiring frames; and I see Mr. Gemmell is in difficulty about his wiring. Allow me to suggest a remedy, although I do not use or believe I need wired frames. Why not put in your finest wire poultry netting? You see, by this plan you get both horizontal and perpendicular wires, or you can have all diagonal. It would be strong enough either way. If you do not care about trying it yourself, you might ask Mr. Gemmell to try it, and let me know the result the next time I see him.

Bees have generally wintered well here, owing to the mild winter. I winter mine in the cellar. I omitted removing entrance-blocks from a strong swarm in an 8-frame L. hive, but they squeezed one end of one block out so that one bee could crawl out at a time over the end of the block. The top was tightly sealed, but they came out all right.

Kintore, Ont., May 10, 1890.

J. W. WHEALY.

Poultry netting is not made of small enough wire to be used in wiring frames; and even if it were, there would be no feasible method of fastening it inside of the frames, to say nothing of the difficulty of imbedding the meshes in the foundation.

NOT IN FAVOR OF THICK TOP-BARS.

I would not have a top-bar in my hives that is over $\frac{3}{4}$ thick. Tuck and staple spacing would not suit me, as that would be a hindrance to handling frames. I have 30 stands of bees. I run my bees mostly for comb honey. I have never used a zinc honey-board in the ten years I have kept bees, and would not have one. I space my frames $1\frac{1}{2}$ inches from center to center, putting in the number of frames desired. If that does not fill the body of the hive, I fill the space left with a division-board, then between the lower and upper story I am very exact in leaving just $\frac{1}{8}$ of an inch, and am not bothered with brace-combs nor queens going above.

I went into winter with 30 colonies on their summer stands, mostly in chaff hives, in fair condition. I have 30 at this writing, in good condition for surplus. I use a topless frame holding four sections, such as I buy of you, and I like them very much.

Akron, O., May 13.

AMOS E. GRIFFETH.

The majority of those who have reported in regard to thick and thin top bars would not agree with you. We can not prevent brace-combs with $\frac{3}{8}$ -in. top-bar above, and we live only 20 miles from your locality. We

are glad to get your testimony in regard to section-holders.

THE MELTED-WAX PLAN OF PUTTING IN STARTERS; 25 TO THE MINUTE, AND 1200 PER HOUR.

I notice in GLEANINGS of May 1, a letter from Dr. C. C. Miller, giving his way of putting in starters. He says he can put in four starters a minute, and Emma can put in 14. I will give you my way of putting them in. I use a small iron pan, with a bottom about 5 in. across, and put enough wax in to cover the bottom about $\frac{1}{4}$ inch. I place the pan on the stove and let the wax melt. I take a board one foot wide and 18 in. long, and sit down close enough to the stove so that I can reach the pan conveniently, and put my sections on a pile (starter side) on the board, and the starters also. I put the board on my lap with starters next to me. I dip the edge of the starters into the hot wax, and then place it on my sections. The first minute I tried it I put on 20 starters; the next minute, I put on 25. I can put on 1200 in one hour, without any extra effort. I have a little girl and boy that lay them away after I get them on. I do not put the sections together until after the starters are on.

Muncy Sta., Pa., May 8.

R. I. CROMLEY.

THE HOFFMAN FRAME, AGAIN.

I notice you inquire in GLEANINGS for May 1 "if there is any one else among your readers who has tried the Hoffman frame." I have used this frame for the past six years, and I find it far superior to any other frame, and I agree with Mr. Beebe in all the points he makes in regard to them.

My frames are the Langstroth size, with top-bars $1\frac{1}{2}$ in. wide at the ends, and notched out $\frac{1}{2}$ in. on each side between the end-bars, making them $1\frac{1}{2}$ in. wide over the combs, so that, when they are placed in the hive, there is $\frac{1}{4}$ in. space between the top-bars, to allow bees to enter the super. For supers I use the T super with $\frac{1}{4}$ -in. bee-space at the bottom, and place the supers directly upon the frames. No honey-board is required with this frame if the super has a bee-space at the bottom, as the top-bars act the same as a honey-board. This I deem a big point in their favor. I produce comb honey exclusively, and in my six years' experience with this frame, without honey-boards, I have had but one section in which brood was placed. When I first began to use this frame I had top-bars $\frac{3}{4}$ in. thick; but I found the weight of the combs caused some of the frames to sag. I also noticed that, where the frames sagged, there were brace-combs built; and where the frames did not sag there were hardly any brace-combs. I then changed from the $\frac{3}{4}$ -in. to $\frac{1}{2}$ -in. top-bars; then the result was, there was no more sagging of frames, and almost no brace-combs.

LOUIS ANDERSON.

Bloomsbury, N. J., May 6, 1890.

Your testimony is valuable, and the more so, as it substantiates what others have said. So you can use T supers on these frames without a honey-board. That's good. Who else has tried these frames?

NO LOSS ON SUMMER STANDS.

I have to report 54 colonies in the fall, and 54 spring count. How is that for outdoor wintering in ordinary box-frame hives, and just as they stood on their summer stands, and, with one single exception, in good condition?

My bees have had so far too much honey from

last year to raise enough brood. That is not room enough; nevertheless, the late, cold, and wet spring will give them ample time to use it all up before they get much from the fields. White clover is blooming earlier than common, with prospects good, when the weather settles. We had a light frost last Sunday and Monday morning, with heavy rains yesterday and to-day.

FRANKLIN GARNES.

Kenna, W. Va., May 14, 1890.

AGAINST SELLING ON COMMISSION.

If the bee-keepers do not adopt some other method of selling their honey than sending it to commission men and letting them sell it for what the grocery men want to give, they might just as well let their bees all die or kill them. As fine comb honey as you ever saw, linden, white as snow, put up in 2 lb. frames, sold last February for 8 c. per lb.; taking out freight and commission, netting the bee-keeper $5\frac{1}{2}$ cts. per pound. If the commission man had been instructed to sell it for $12\frac{1}{2}$ it would have brought it. As soon as I can get time I will give the readers of GLEANINGS my method of selling honey, and how to get a good price for it, as I have always sold my own honey for the last forty years, and expect to if I live forty more.

WM. URIE.

Minneapolis, Minn., April 28, 1890.

FROM 55 TO 115, AND 2700 LBS. OF HONEY, WITH A LOSS OF BUT TWO.

I started in the spring of 1889 with 55 colonies, with quite a per cent of them very weak. I increased to 115, principally by natural swarming. I obtained 2700 lbs. of honey, 2000 lbs. comb, and 700 lbs. extracted, all very nice white-clover honey, for which I realized from 15 to 20 cts. for comb, and 15 for extracted, wholesale. I started into the winter of 1889 with 115 colonies, with natural stores, no feeding, and came through with 115 up to March. I lost two in March, and two more proved to be queenless; the rest are in good shape, with a prospect of a good season in view. I wintered all on their summer stands, with sawdust cushions over brood-frames, in improved Mitchell hives, double-walled.

S. R. MORRIS.

Bloomington, O., May 10, 1890.

HOW AN UNTESTED QUEEN AND 1 LB. OF BEES DID.

I ordered 1 lb. of Italians, and an untested queen; but through your kindness you sent 2 lbs. of bees and a queen. As I told you in a letter, I put the 2 lbs. of bees into the hive in the greatest hurry, not thinking that, right after destroying the black queen, the blacks might destroy the new queen; and as it came to my mind that might be the case, I let the white sheet lie before the hive for about three days, to take a look every morning to find the dead queen dragged out of the hive, but could find no dead queen, so I did think all right.

By this time, and several weeks ago, I could see the young yellow-striped bees come out to try their wings for the first time in the nicest way. So I have turned the black cross colony into the most beautiful Italians.

The 1 lb. of bees and Italian queen I got of you last June are now a strong colony.

JOHN SLAUBAUGH.

Eglen, W. Va., May, 1890.

PROSPECT VERY POOR FOR HONEY SO FAR.

There are no material signs of swarming, and white clover is just beginning to bloom. It is still very cold, and we have had four frosts this month.

Yesterday, the 15th, was so cold that bees did not fly much. Bees are mostly in light condition. So far they have wintered well, but spring weather is very cold.

WM. ST. MARTZ.

Moonshine, Ill., May 16.

HORIZONTAL WIRING; NO SAGGING OR BOWING OF COMBS.

I have been reading GLEANINGS with interest, and I have seen a great deal said about wiring—which is the best way—and I should like to say that I have been using the horizontal wires for about ten years, and most of the time only two wires; but I prefer it three wires, and I never have had any trouble with foundation sagging or bulging out. I think that the greatest trouble with foundation sagging is that the wires are not stretched tight enough. If the wire sags, the foundation must. As for tin bars, I have never used any. I have had no use for them; and as far as I can see, they are a bungling affair. I use the L. frame, and prefer it to any other that I have used.

MY HONEY CROP FOR 1889.

Comb honey, 1000 lbs.; 500 extracted. I commenced in spring with 30 colonies; increased to 45.

Fremont, Mich., May 16. SAMUEL BOYD.

BACKWARD WEATHER.

You will see by my report that we have lost pretty heavily in bees. These have mostly died during the last two months; and although we have been feeding some we did not watch them closely enough. It was warm here the greater part of the winter until February, causing the bees to fly a good deal, and consume considerable honey. For the last four or six weeks we have been having almost continual cold rains, which keep the bees confined to the hives when they should be gathering honey. A little more attention and feeding would have saved some that we have lost; but we dislike to inaugurate a regular system of feeding, and have been in hopes of sunshine. However, the most of our colonies are in fair to good condition; and the prospects for a big crop of honey are good, provided we get clear weather soon, as the white clover is in better condition than it has been for years past.

S. E. MILLER.

Bluffton, Mo., May 18.

SELLING EXTRACTED HONEY; CANDYING A BAD FEATURE.

I have been selling honey in connection with maple sugar and syrup for six years, doing a successful business all through New England, but principally in Massachusetts. When I first commenced in the business I bought pure white-clover extracted honey; but experience soon taught me that white-clover honey would not hold trade, as it would soon become candied; and when I went around the next time I was politely informed that they did not care to buy brown sugar and pay a honey price. I would tell them that it was sometimes due to the action of the atmosphere, but I suppose they thought it was due more to my action than that of the atmosphere.

I saw I must make a change if I held my trade. I tried some orange-bloom honey, shipped from Florida, and found it to be the best yet. I have sold it for four years now, and where I sell it once I sell again. It will retain its liquid form two years or more. If we could only keep our white-clover extracted honey from becoming candied it would give

general satisfaction; but until then the public will persist in saying they "knew it is more'n half sugar."

E. U. FOSTER.

Waterbury Center, Vt., May 6, 1890.

NO LOSS IN WINTERING, AND PROSPECTS FLATTERING.

The outlook for bees in this locality is very flattering. Colonies are all strong, and all I have heard from have wintered well. I wintered 50 colonies on their summer stands, and did not lose one. All of them are as strong as they were last year the 12th of June. On the 14th of this month I had a new swarm. It was caused by feeding. There was little but willow in bloom at the time. It was never known to occur in this locality before.

Myrtle, Pa., May 19.

E. A. PRATT.

DECOY HIVES, AND THE LAW CONCERNING.

It is my mind that this law was framed by bee-hunters, and presented to our legislature without consulting the bee-keepers. The law should be repealed, for, as I understand it, it does not even allow us to have an empty hive in our apiaries. I claim we should have the right to decoy our own bees as much as we can. Hunters and sportsmen have caused many laws to be made to the farmer's sorrow. Now, why not put this to vote, and see how many are in favor of repealing this law? I say, repeal it.

E. S. ANDRUS.

Torrington, Conn., May 21.

VERY DRY.

The prospects are very poor for a good yield of honey. It has been so dry that there is no white clover, and it has been very cold since May came in. It is still cold, with hard frost at night, with frequent snowstorms. All fruit will be killed, and the bees have not worked a single day on fruit-bloom.

Minneapolis, Minn., May 20.

WM. URIE.

SWARMING, AND LOTS OF WHITE CLOVER.

Bees commenced swarming on the 1st of May. Swarming is a month late. I have hived 15 swarms so far. I never saw so much white clover. Bees are working with a rush. I never saw such a large swarm. Your paper is just right for twice a month.

G. B. CARTMELL.

Jackson, Tenn., May 19.

UNJUST DISCRIMINATION BETWEEN HONEY AND FISH IN FREIGHT RATES.

I should like to say, "Honey in Pails" is double first-class, while fish in the same kind of pails is fourth-class. This hurts me badly, for I have worked up a market for honey in 20-lb. wooden pails. It ought not to cost more to ship extracted honey in large wooden pails than comb honey in glass boxes.

F. WILCOX.

Friend W., there are several reasons why railroads charge more for honey than for fish. The first is the value. If they spill or damage a pail of fish, it does not amount to very much compared with a pail of honey. Another thing, I suppose the reason why honey in wooden pails is rated higher than honey in boxes is because of the liability of being tipped over and spilled. If honey is put into pails having an absolutely tight cover, say something like syrup-cans, so they will not leak any side up, it should go at as low a rate of freight as anything else put up in similar tin cans—that is, where the value is about the same as the value of

honey. Liquid paint, for instance, is a very large article of traffic, and it is put up both in tin pails and wooden kegs, and, if I am correct, honey can be shipped about as cheaply as paint. Very likely, however, the matter needs looking after.

MYSELF AND MY NEIGHBORS.

O thou of little faith! wherefore didst thou doubt?
—MATT. 14: 31.

THERE are in this world lovable people, or, if you choose, lovable neighbors. There are also neighbors—just a few of them—who are *not* lovable. It is our duty to love them, nevertheless; for Jesus said, "Love ye your enemies." Doubtless most of you know people whose very presence seems to bring something pleasant and cheering. Every word they speak indicates faith, energy, go-ahead, and hopefulness. Some *writers* have a faculty of making their words so attractive that we like to read them and dwell on them. Their bright expressions we like to read over and over again. Well, of late I have been enjoying myself by reading over and over the words and expressions of Christ Jesus; and the more I read them, the more I love them. I am not a great *reader* of the Bible, and I doubt whether anybody ever sees me reading it more than a few minutes at a time. Sometimes I read a chapter, but not often more than that at once. It used to trouble me somewhat because I did not like to read the Bible as some do. It is too much for me; that is, to read very much of it all at once. A verse or a part of a verse seems to be all I can manage or comprehend at one time; and sometimes a little bit of verse will last me several days. The more I dwell on it and think about it—the more I repeat it over and over—the more it becomes music to my soul. And especially do I delight in making it fit into the subject of conversation that is going on about me. One of the brightest little texts I ever got hold of is the one about which I am writing: "O thou of little faith! wherefore didst thou doubt?" Matthew, Mark, and John, tell us the little story about Jesus walking on the water. After feeding the five thousand, Jesus saw fit to tell his little band to get into a boat and cross the sea alone. He dispersed the multitudes, and sent his followers away, and then he went up into a mountain to pray. He told the little band to go to some point on the other side of the sea, or lake. The distance was so great, however, that they did not reach their destination before morning. Late in the night they had a contrary wind, and the little boat was tossed by the waves. By and by somebody was discerned in the darkness, walking on the water. No wonder they were afraid, and supposed it was a spirit, or something supernatural. They forgot all about the miracle of the loaves and fishes, and of the Lord and Master who was away, they knew not where. But he, in his loving kindness, very soon dispelled their fears and bade them "be of good cheer;" and then he added,

" 'Tis I; be not afraid." We can well imagine the relief they felt. Perhaps, notwithstanding his cheering words, however, they felt a little uneasy still. Our bold and impulsive friend Peter, however, was the first to recover, and grasp hold of the fact that there could be no *possible* danger while the Master was near. With his reckless daring and ready response he burst out with the words, "Lord, if it be indeed thou, bid me come unto thee on the water." I can imagine that the other eleven looked at him in open-mouthed wonder and surprise. Did anybody ever hear of such assurance? Perhaps not. But the Master was pleased. Why? Because it indicated faith—faith in his Lord; and if any thing ever pleased Jesus, and made him smile, it was perfect, unreserved confidence, not only in his *wondrous power*, but in his *loving kindness*. He replied, as you, my friend, may have said to one of the little ones of your household—one that is just learning to walk, for instance. We do not know whether the Master put out his hands to him or not; but he gave his permission, and encouraged him in the same simple word, "Come!" Most of us would have been very apt to back out, even then. Not so with Peter. Over the side of the boat he went, in a twinkling. Out upon the water he stepped with perfect faith, and safely stood and walked upon the yielding element. Had Peter's *faith remained* perfect, his *walk* would have remained safe and perfect also. But the wind was still boisterous; the waves were rolling and tumbling. Very likely he got dizzy, and then began to be afraid. He started out well, but he lacked *enduring* faith. He began to sink. He did not, however, turn back and grapple for the boat. We know he was a good swimmer, for on one other occasion he jumped out of the boat, and swam ashore to meet the Master. But he did not trust to his skill in swimming, on this occasion. As he began to go down in the water, we may suppose that he raised his hands imploringly toward the Master as he said, "Lord, save me." I wonder if it is not possible that Jesus smiled as he saw his fright. How often have I laughed outright in great merriment to see the little ones of our household, when I was giving them their first lessons in walking, become affrighted when there was nothing to fear!

Jesus was near enough so he actually reached out his hand and caught him. And then comes that bright, glorious, hopeful, happy, beautiful speech, the text I have said over and over so many times, and yet never tire of repeating: "O thou of little faith! *wherefore* didst thou doubt?" May I take the liberty of paraphrasing it a little? Didn't his Lord mean, even if he did not say, "Why, Peter, I am surprised at you. How couldst thou fear when thy Master was so near by? Why should my good friend Peter, who started out so well, so full of faith and ambition, and so full of perfect trust and confidence, become demoralized and affrighted simply because the winds and the waves were boisterous? Didst thou forget that, at my command, the winds and waves obeyed?" And that one word,

"wherefore," like a beautiful bar in a strain of music, as I repeat the text over and over, comes with wonderful beauty and power. It seems to say, "Where, in all your experience with me, have you found reason to be afraid? Have I ever failed, or have I ever been mistaken? Did you ever know me to call upon the elements of nature when they were not obedient to me? Where in all our past pleasant intercourse and acquaintanceship did you all together have reason for doubt or fear? Can you not trust me, my good, faithful, and devoted friend Peter? Can you not trust *me*?" Matthew tells us no more, but only adds that, when they were come into the ship, the wind ceased, and together they united in worship, saying, "Of a truth, thou art the Son of God." They soon landed, and then commenced the busy life again. When the men of that place had knowledge of him, they sent into all the country round about, and brought the sick and the diseased. And now we are told that they begged only for the privilege of touching the hem of his garment; and as many as even *touched* him were made whole.

And now, dear friends, is there not a practical application for us? Is not the great trouble, and the great lack of all humanity, in the same line of thought of Peter—"O thou of little faith"? Is not that *your* trouble, dear reader? It surely is *mine*. Jesus is near, and ready to help. And not one of us in all our past experience can say that we have trusted him in vain. A new railroad is coming through our town. Crowds of new people are already camping in the suburbs. At the dinner-table some one expressed a fear that this new element coming into our midst would be demoralizing to our community. I knew as well as they that there was *danger* in this direction; but yet, if it is Christ Jesus that we are trusting, have we any thing to fear? I smiled as I commenced my little text, "O thou of little faith! wherefore didst thou doubt?" A few weeks ago two good friends of mine had trouble. They are both professing Christians, but they talked hard, and I fear they did some things besides talking. With all my busy cares I felt a responsibility laid upon me. I must go to each of them—perhaps get them both together, and may be plead in *rain* for Christ Jesus the Savior. I feared it would not do any good. As we knelt at our bedside at night, I prayed earnestly that God would put it into their hearts to consider how wrong it was for them to cherish such feelings toward each other. I prayed that they might *each* feel moved to ask forgiveness of the other. What did I do next morning? Why, I went to one of them with a very sober, downcast face, and with a trembling voice commenced my task. To my surprise he laughed outright as he put his hand on my shoulder, and said, "Why, Bro. Root, we knew as well as you do that we were out of place as Christians, and we have made it all up, and fixed the things that made the trouble, so I think I can assure you it will never happen again." I opened my mouth in astonishment as my face softened into a smile, as I realized that

I was relieved in this unpleasant task. *Then* I remembered the prayer of the night before, and the text stood out strong and clear before me—"O thou of little faith! After your earnest prayer last night, *wherefore didst thou doubt?*" As I look back and see the victories that have come from prayer, and the obstacles that have been overcome ever since I chose Christ Jesus as my guide, then it comes again, as I look in open-mouthed astonishment, and see what changes have been wrought through the name of Christ Jesus; and I say to myself fondly, "Wherefore! wherefore! *wherefore!* didst thou doubt?" A few weeks ago I stood on the brink of danger. I seemed, for the time being, changed over; some evil spirit had got a hold upon me. I once heard of a man who felt sure he could keep sober if he kept off from a certain street. On that street was a saloon that he knew from sad experience he was not capable of passing by. The tempter was too strong for him, if he even passed before the door. He avoided that street, and passed around, even though it cost him considerable additional travel when he was tired out and weary. But it was the safer way. And yet it was very *hard* to keep *away* from that street. Although he knew from past experience that it was dangerous, still he could hardly keep away from it. I think he was wise in doing so. I have been through a similar siege with the tempter. For many weeks, in my want of faith I rather concluded that the rest of my life would have to be passed in just that way—wearing myself out with *useless travel* just to keep out of *Satan's* way. When it occurred to me, however, to reach out in utter helplessness, as did Peter, saying, "Lord, save, I am utterly discouraged in trying to save myself, and have lost hope; save me or I perish"—when I got right *there*, like a flash of light the tempter, with all his machinery, gathered himself up and departed. There are no saloons at all now on that dangerous street; in fact, *there is no such street*. The shackles have fallen, and I smile to think of them now. The whole trouble was little faith. It was in Doubting Castle that I was imprisoned, and the key of promise was hidden in my bosom, *unused* because I *forgot* I had it. Years ago, when I knelt down by myself and uttered that first prayer to my Maker, "O God, if there be a God that cares for a poor helpless child to whom he has seen fit to give a place in this great universe, help me if thou carest for me"—when I uttered that prayer I could scarcely comprehend that Jesus could or would help one who did not help himself any better than I had been doing. I knew I was *bad* and *wicked*, but I had got it into my head and heart, that, *before* one prayed he must be *good*. I could not comprehend that there was any possible help for one who kept slipping back and yielding to temptation. When help came, and I felt a strong arm round about me, I was utterly astonished. It was a new experience, and a revelation too. And, dear friends, this experience and this revelation continually come up; and as I am helped out of one piece of miry

clay after another, I am astonished again. My faith seems to be continually settling back, notwithstanding all these victories. And this is why I so cling and hold on to this beautiful, bright little text of mine—"O thou of little faith! wherefore didst thou doubt?" And now, dear friends, in all this talk—in fact, in most of my talk for months back, I have been trying to impress the thought that there is help for *sinners*; there is help through Christ Jesus for those who feel themselves to be *helpless* sinners. A letter just at hand illustrates more fully what I mean. It comes from away down in Texas; but notwithstanding, it echoes the thought of many other poor souls scattered far and wide throughout the world. Please read:

Mr. Root:—I used to keep bees, and was once a reader of GLEANINGS. I was a good man once; but since my wife died I have become a drunkard. I have made promises, and broken them, until I don't believe the *Christians* here have faith enough in me to even pray for me; and the *sinners* don't like me now as they did when I had money to spend with them for whisky. I have a good old Christian mother, and I write to beg you to *help* her pray for me. I am a young man yet. I think there is still hope for me. By the help of God I won't touch any more whisky. Please pray for me. I would not write you this way, but I believe you are a good Christian.

Texas, May 13.

I want to say, first, that my recent experiences have prepared me to have more charity for those like the writer of the above than I have ever had before. Our poor friend has written to me when utterly discouraged. We judge from his letter that he is almost on the point of giving up. There is something almost plaintive in his honest, frank confession. He does not beat about the bush, nor use polite words to tell the truth as it is. He says, "I have become a *drunkard*." Why, the very word sends a chill through one's veins. Of late it has become so customary to use some softer or more polite word, that we are startled when a poor sinner uses the term "*drunkard*." And he says, further, that he has made so many promises only to be broken that he hardly believes that the *Christians* around there have faith enough to pray for him. His money has gone, and his *companions* who are, like himself, *sinners*, are gone also. He is alone, and clear down to the bottom, probably. There is one poor soul, however, who still hopes and prays—an old Christian mother. But even her prayers, and thoughts of that pious mother, have so far been of little or no avail. He remembers his bee-journal and the Home Papers; and, as a last hope, he writes to me, begging a favor. The favor is, that I shall help this poor old mother *pray*. Oh how I wish I could be by her side for just a little while! How I should like to hear her tell me the sad story of her lost boy! "Lord, help!" wells up in my heart as I read the words. "Lord, help this poor soul struggling in helpless bondage. Help him as thou didst help me when I was a slave and in fetters. Help all who are in the fetters

of sin; and, O Lord, hear this poor old mother's prayers, and help our poor friend in his *utter* helplessness. May he look up to thee, as did poor Peter when he said, 'Lord, save me.'"

Dear friends, I do not mean to say that Christ Jesus will or can help unless we come to him. You will remember that, in his own village of Nazareth, none were healed. The reason was, that nobody came to him asking to be healed. They hadn't even faith enough to *come*. And it is so with us. We must come to him. "Him that *cometh* to me I will in nowise cast out." If the writer of the above letter were invited to come to Jesus, and should refuse, and make excuses, there would be no help. If, however, in his utter discouragement and despair, he should come, saying, "Lord, help, for I have nowhere else to go," salvation is sure—that is, providing he holds to that attitude. Should he change his mood and reject the Savior, he is lost. "He that *believeth* on the Son hath everlasting life." Now, it is not enough to *say* that we believe. Words are well, but they must be the expression of the heart. What must the sinner do? He must from the heart say, "Lord, help," at every turn. When tried and sorely tempted he must from the bottom of his heart keep calling and begging for help. So long as he does this with an honest sincerity of purpose, and with an abiding faith, he is safe; and in a very little time he will come to look back, and smile to think of how little he could comprehend or understand what Jesus can and will do for those who trust him. He will smile as the wondrous truth bursts in upon him in the light of the beautiful words of my little text. I say *my* little text, for I have been making it mine; but, dearly beloved reader, let me give it to *you*, that *you* may make it *yours*: "O thou of little faith! wherefore didst thou doubt?"

TOBACCO COLUMN.

CONDITIONS UNDER WHICH WE GIVE SMOKERS TO PERSONS WHO STOP USING TOBACCO.

First, the candidate must be one of those who have given up tobacco in consequence of what he has seen and read in this department. Second, he promises to pay for the smoker should he ever resume the use of tobacco in any form, after receiving the smoker. Third, he must be a subscriber to GLEANINGS. Any subscriber may, however, have smokers sent to neighbors or personal acquaintances whom he has labored with on the matter of tobacco-using, providing he give us his pledge that, if the one who receives the smoker ever uses tobacco again, he (the subscriber) will pay for the smoker. The one who receives the smoker in this case need not be a subscriber to GLEANINGS, though we greatly prefer that he be one, because we think he would be strengthened by reading the testimonials from time to time in regard to this matter. The full name and address of every one who makes the promise must be furnished for publication.

REDEEMED FROM BONDAGE.

I have been a slave to the filthy habit for about 25 years. One year ago last November I quit chewing and went to smoking, and the latter was the worse of the two habits. Last August I attended a revival meeting, and became deeply convicted of my sins, especially in regard to the way I was raising my family, and the example I was setting before my boys (I was a backslider). I resolved to "return to my father's house" again, and seek salvation. Oh the joy and comfort it gives one to

know that he is freed from sin and evil habits! I smoked but once after I was converted. The second time I filled my pipe I was condemned, and those words came into my mind, "Cleanse yourselves from all filthiness of the flesh." Pipe, tobacco, and all went into the stove; and, God being my helper, I will never be found guilty of the habit again. About that time my wife was reading GLEANINGS, and she said, "Listen; A. I. Root offers to give a smoker to any one who will quit the use of tobacco." I said, "Amen! I want to sign a pledge of that kind. I want the world to know that God has power on earth to cleanse his children from all unrighteousness, if we only put our trust in him." Go on, Bro. Root, sowing seeds of righteousness. May God bless you, is my prayer. My wife says, if I ever commence the use of tobacco she will send you the price of the smoker.

Glenwood, Iowa.

DANIEL BARBEE.

May God be praised, friend B., for your bright, clear, unconditional surrender; and especially do I commend your willingness to stand out before the world, making your retreat so sure that you can not go back, even if you would. And I am glad, too, to hear the good wife say that, if you ever begin the use of tobacco again, she will report, even if you should backslide so far as to incline to neglect it.

A MINISTER OF THE GOSPEL WHO IS KILLING HIMSELF WITH TOBACCO.

We have a minister here who is a member of our conference, and who is killing himself by smoking tobacco. We are taking pledges from him to quit; and as we all read (my) GLEANINGS, your most excellent magazine, and among them the pledges, I promise to send you the price of a smoker if he returns to it again. Send it to my address at once, and I will deliver it.

M. K. LITTLE.

Fort Worth, Texas, March 2.

WHAT A LAWYER THINKS OF TOBACCO.

I have induced my boy, Wm. Lucas Dillard, to quit the use of tobacco, offering, as an incentive, your offer of a smoker. I tell him that, if a stranger, who perhaps will never meet him this side of the ultimate tribunal, can so deeply feel for the follies of youth, there must be something vitally and radically wrong in the abominable practice of tobacco chewing and smoking. My boy has a manly sense of duty; and if he puts himself voluntarily under obligations to do something, I'm sure nothing will divert him.

H. M. DILLARD.

Meridian, Texas, May 6.

GOING SECURITY.

There is a young man, a neighbor of mine, who is reading my GLEANINGS. He keeps bees, and says that, if I will get him a smoker, he will dispense with tobacco entirely. Send the smoker; and if he ever uses the weed again I will pay for the smoker. His name is Burt Jenkins.

F. H. KUNKLE.

Camden, Mich., April 30.

TAKING THE PLEDGE AFTER HE HAS STOPPED A MONTH.

Please send a smoker to A. J. Foster, Winthrop, Iowa. I will pay for the smoker if he ever smokes again. He has stopped smoking now for a month. Of course, Mr. Foster understands that he is never to use tobacco in any form, and this is right.

Winthrop, Iowa, Mar. 24.

E. P. BRINTNALL.

A HUSBAND WHO HAS QUIT.

M. C. Hays has quit the use of Tobacco. You will please send him a smoker. If he ever resumes the use of tobacco, he promises to pay for the smoker.

Mrs. M. C. HAYS.

Temperance Hall, Tenn., Apr. 21.

SECURITY FOR ANOTHER.

A friend of mine has promised to stop using tobacco if you will send him a smoker. If you will send one, and he ever uses tobacco again, I will pay for the smoker. I never used tobacco, and I thank God that I never formed that habit.

McKean, Pa., Apr. 4.

D. E. PORTER.

YOUNG MEN TAKING WARNING IN TIME.

I take pleasure in reading your Tobacco Column. It is gratifying to see so many young men take warning while on life's meridian. Mr. L. W. McGuire has broken from the useless tobacco habit for seven months, and desires a smoker. He pledges that, if he ever uses any again, he will pay for the smoker.

G. W. MCGUIRE.

Dark Ridge, N. C., Mar. 14.

A BOY WHO HAS FOUND A BETTER USE FOR HIS MONEY.

I am a boy 17 years old. I have been in the habit of using tobacco some, but am trying to live a Christian. I have concluded to do without it, and that I can put my money to better use, and feel better over it. Please send me the smoker; and if I should use tobacco any more, I will pay you for the smoker.

BERTIE S. EVANS.

Mendon, Mich., May 9.

QUIT AFTER 12 YEARS.

I have received GLEANINGS 7 years, and have concluded to quit the use of tobacco. I have used it twelve years. If I am entitled to a smoker, please send with other goods. If I use the weed again I will pay for smoker.

J. H. KLINE.

Wooster, O., Apr. 18.

IS INDUCED TO TAKE THE PLEDGE THROUGH THE INFLUENCE OF THE TOBACCO COLUMN.

Through the influence of the Tobacco Column I have made up my mind to quit the use of tobacco. I have used it for five years off and on. You can send me a smoker, and if I should resume the use of it again I will pay for the smoker.

Wayville, N. Y., Mar. 26.

O. C. ABEL.

A FRIEND GOING SECURITY.

Please to send me a smoker. I have a friend, D. F. Stewart, who has quit the use of tobacco, and agrees that, if he uses it again in any manner whatever, he will pay you the sum of \$1.00 for the smoker, God being his helper to enable him to quit using the weed. And I promise to see that he fulfills his contract.

G. F. TYLER.

Honey Grove, Tex., Apr. 25.

TWO PLEDGES.

In reading GLEANINGS I feel as if we were old acquaintances, and without it we should be lost. I hope that it will be weekly soon. I promised an old uncle of ours that, if he would quit chewing tobacco, I would get him a smoker; so he quit on the first day of this year, and says he will never use it again. If he breaks over I will pay for the smoker. His address is V. B. Lindsay, Nebraska, O. I have taken the pledge too; and if I ever break it I will pay double price for it.

J. N. RILEY.

Washington C. H., Ohio, Mar. 5.

The Tobacco Column for this issue, as the friends will observe, is, a great part of it, going security for some friend or relative; and this is exactly what we want. In fact, I should much prefer having the pledges given in this way. We wish the one who pledges himself, however, to be a subscriber to GLEANINGS. The one who gives up using tobacco need not necessarily be a subscriber himself. In all cases, however, his own good will depend very much on GLEANINGS being well circulated in his own neighborhood. The second one who takes the pledge is a minister of the gospel. One of his people agrees to deliver the smoker, and be responsible. May the Lord bless and strengthen this minister.

EDITORIAL.

Lord, save us: we perish.—MATT. 8: 25.

We have at this date 9931 subscribers.

CONVERTING COMMON FRAMES INTO HOFFMAN FRAMES.

ON page 435 Ernest speaks of this arrangement as if it were new. It is new to him, but the same thing was recommended and tried before GLEANINGS had an existence. It was given in the *American Bee Journal*; but I believe that those who tried it afterward pried off the strips and threw them away. Present needs, however, may make a difference.

BEE-CRADLES.

SOME years ago, before our present proof-reader and translator was here, we received a letter from a friend in Germany. As it was written in the language of that country, we sent it to a linguist to translate. It so happened that the translation came back with the word "bee-cradle." It was very easy for us to guess that, instead of bee-cradle, our German friend meant "queen-cell." We had forgotten all about the circumstance until we just received a letter written by a German friend in Missouri, he writing in French. Being more or less familiar with the German idiom, he sent an order for a lot of "bee-cradles," as large as a certain piece of paper. Our proof-reader studied all the way to dinner and back again as to what "artificial cradles" might mean, as he had never used any other, and yet he had never seen Mr. Warner making any in the saw-room. Finally the incident related above came to his mind, and he then concluded that our friend wanted *foundation*. This shows the difficulty in translating the technical meaning of a word when it is used in its common acceptation. Quite likely many passages in the Bible which seem so incomprehensible are owing to the fact that the translators spoke of "cradles" when "honey-comb" was meant.

SELLING SECRETS FOR MONEY.

A GREAT number of communications have been received in regard to the revival of the water-cure treatment. We have space for only two of them, and I wish to give these two because they illustrate so forcibly how it is that good earnest Christian

people may differ so widely in opinion. Here is the first:

FRIEND ROOT:—In my last GLEANINGS I see an article by you about A. Wilford Hall's great discovery. The true Christian, like his Master, is ever ready to help all of God's children in every way in his power. I know some, like yourself, who have signed the pledge very reluctantly, and some who said they could never sign it, though it should be the means of saving their lives, if they could not impart to others that which has been a blessing to them.

Yours in the cause of blessings for the world,
Sulphur Grove, O., May 20.

S. J. ARNOLD.

Thank you, friend A., for your very kind words. I think we all agree with you, at least in the main.

The next is from one of those very ministers of the gospel who have given their names to Dr. Hall, to help him advertise:

BRO. ROOT:—I received GLEANINGS to-day, and was surprised to see an article in reference to Dr. A. Wilford Hall's remedy for curing disease without medicine. What hurt me all over, and down in my soul, was that you say I ought to be ashamed of myself for indorsing the remedy. I have been trying to preach the old, old gospel of Christ about fifty-five years, and I am not aware that anybody ever before said I ought to be ashamed of something I had done. In my indorsement, which you can find in the Microcosm, I stated I would not quit the practice for the half of Texas, and I repeat here that I would not. I have been using it about eight months, and, humanly speaking, it saved my life. If the doctors knew of this, why did they not charge me for a prescription and tell me it would cure me? Dr. Hall admits the remedy has been known to some extent, but never in its application, as he has revealed by his own experience of forty years ago. I must say I think you are slandering him. I feel sorry to have to write to you in this way, but I could not satisfy my mind without doing it. If you had been in the spirit in which you mostly write, I am very doubtful about your writing any of the article. Our business relations have been very satisfactory, and I wish you every good; but I think you have made a mistake. I remain yours very respectfully,
Luling, Tex., May 22.

S. C. ORCHARD.

Dear brother, I can not for a moment doubt the kindness of your heart, or in the least the honest sincerity of your motives; still, I think you are making a mistake. The editorial you allude to was written by your old friend A. I. Root himself, and I think that no motive but love to his fellow-men prompted him to write it. No doubt you have been greatly benefited. You are full of enthusiasm in regard to the plan, new to you, of treating disease without medicine. Are you sure that you consulted a physician in regard to your poor health, and stated to him exactly where you thought the trouble lay? Perhaps our physicians have been remiss. Doctors, and others who have much to do with humanity, are used to these sudden excitements in regard to certain things that come up. Very often it is a revival of some old thing, and sometimes it is really some new development; but, dear brothers, all of you, shall we not keep in sight that grand truth once uttered by Gamaliel when he said, "If this counsel or this work be of men, it will come to naught; but if it be of God, ye can not overthrow it"? Meanwhile the testimony of our best doctors, ministers, and professors in our colleges, will say unmistakably that selling secrets for money, in answer to broadcast advertising, is certainly not only wrong, but it is not up with the spirit of the age and of our American institutions. The man who does it has a bad heart. I am well aware that Dr. Hall gives his pamphlet to ministers of the gospel, free of charge; but, dear friends, is not this whole custom wrong, and bad in its tendency, giving ministers certain things with the understanding they use their influence to get people at large to buy? A great many pastors of churches refuse to receive any thing at less than the price charged other people, in order that they may never be accused of having selfish motives in what they advise. Our good friend Terry recently refused to receive a potato-digger as a gift. He insisted on paying the same price that others do, so that he might, when writing through the agricultural papers, express an unbiased opinion either for or against it.

THE NEW YORK STATE BEE-KEEPERS' ASSOCIATION HAS gotten out a very neat and nicely printed report of its 21st annual meeting, held at Rochester, Feb. 6, 1890. A copy of the same can be furnished by the secretary, Mr. George H. Knickerbocker, Pine Plains, N. Y.

PROSPECTS GOOD.

ALTHOUGH the rains have been rather excessive and frequent throughout the country, the prospects are generally good. White clover is reported everywhere as doing finely; and if we do not have rain or cold through the time it yields nectar, there will probably be a pretty good yield from this source.

BEE-KEEPING FOR PROFIT.

THIS is the title of a pretty little work by Dr. G. L. Tinker, of New Philadelphia, O. It is nicely printed, and well arranged. Each topic is put in big black type, for the convenience of the reader. It details Dr. Tinker's new system of management in connection with the new hive. Price 25 cents, postpaid. Address the author, as above.

BEEES AND HONEY.

THIS work, by T. G. Newman, has just been revised. It has been largely re-written, and is fully up with the times. It contains 200 pages, and is well and fully illustrated. Of course, being published by T. G. Newman & Son, its typographical appearance and binding are par excellent. It is written in Mr. Newman's vigorous style, and fills an important place in bee-literature. Price \$1.00, postpaid. We can furnish it if desired.

MANUFACTURED SCIENCE, AGAIN.

THE *Pharmaceutical Era*, of Detroit, Mich., for May 1, contains a brief summary of Mr. Allen Pringle's article which appeared in the *Popular Science Monthly*, as above. After quoting Prof. Wiley's statement in the *Popular Science Monthly* for 1881, to the effect that "commercial honey is entirely free from bee mediation, made of paraffine filled with glucose by means of appropriate machinery," and after quoting his lame apology seven years afterward, to the effect that he repeated "this statement more in the light of a pleasantry than as a commercial reality," and that he does not believe it possible to imitate comb, etc., the editor says: "If the latter gentleman did not at the time, and does not at the present believe in the existence of a manufactured honey, as his last-quoted statement above would seem to indicate, he certainly owes it to himself and the chemical fraternity in general to offer a satisfactory and sweeping retraction."

Yes, sir, he certainly has owed it ever since 1881 to himself and to the chemical fraternity, and also to the bee-keepers all over the land, to offer a satisfactory and sweeping retraction. Prof. Wiley is certainly put in a very bad light in scientific circles. The only thing he can do now is to offer an humble apology and sweeping retraction. A scientific man in his position in the government ought to be ashamed of himself for all these years of silence. We are very glad that Mr. Pringle has shown him up in scientific circles in the vigorous manner he has. The editor of the *Pharmaceutical Era* closes up with this paragraph:

"As the matter involves primarily the integrity of a well-known scientist, and, secondarily, the reliability of important methods of chemical analysis, it is

to be hoped that it will receive the careful attention of chemists."

We trust this matter will now be taken up and circulated over the country; and that the pressure will be so great upon the professor that nothing but a satisfactory and sweeping retraction and apology will be forthcoming.

YELLOW BANDS; BEAUTY VERSUS UTILITY.

ONE of our subscribers, Mr. Jacob T. Timpe, of Grand Ledge, Mich., sends us some yellow-banded workers. It is proper to say, however, that these bees show the characteristic Cyprian shield at the base of the thorax, and probably have a large percentage of Cyprian blood, although our friend said they were very gentle. Cyprian bees show wider yellow bands, and are more inclined to show the fourth band, than are the ordinary pure Italians. Since our editorial on page 378, in our last issue, our apiarist reports some four-banded bees in our own apiary. By looking up the record we find that the queen came from Mr. W. P. Henderson, of Murfreesboro, Tenn. Mr. H. is breeder of nice queens, and a fancier of yellow bees. We hope that our friends, in selecting for color, will not overlook the matter of utility. Perhaps we can have beauty and utility combined. There are several desirable qualities which we should like to have in our bees; and these might be stated in the order of their value thus: Good workers; non-swarmlers; hardiness; gentleness, and beauty. What we want most is bees that will secure large yields of honey when others at the same time will be getting but a small yield; and if beauty can be hitched on too, we shall not, of course, object. But there is a little tendency to overlook working qualities for golden yellow bands. In fowls, beauty and business often go together. The writer (E. R.) has some White Leghorn hens "over home" that lay eggs every day, Sundays included, week after week. They haven't time to sit; and are there any prettier hens than White Leghorns? Now, then, can the bee-fancier do as well as the poultry-fancier?

PRICE LISTS RECEIVED.

The following parties send us their price list:

J. B. Kline, Topeka, Kan.

BEEES AT BUYER'S RISK; 50c PER LB. J. J. HARDY, Lavonia, Franklin Co., Ga.

HONEY-EXTRACTOR FOR \$5. Almost new. W. C. MARTIN, Ashley, Del. Co., O.

COMB FOUNDATION AND BEESWAX ADVANCED.

We are compelled again to advance the price of comb foundation, because of the advance in beeswax. This has been slowly increasing in price for two years past, with slight fluctuations. We have to pay now, on an average, 7 to 8c. per lb. more for wax than we did two years ago. We dislike to raise prices, and have been holding off, working on smaller margins, hoping wax would go no higher; but it is impossible longer to sustain our catalogue prices. We will pay for average wax, delivered here, 27c. cash, 30 in trade, and the same will be sold at 33c. per lb. for average, and 38 for selected yellow. Price of all grades of comb foundation is advanced 8 cents per pound over January prices, taking effect June 15.

A. I. ROOT, Medina, Ohio.

MISMATCHED QUEENS.

Having bought up a few hybrid colonies which we desire to Italianize, we offer for sale some 18 or 20 hybrid queens. To get rid of them early, we will sell them for 50 cents each until disposed of. Some of the queens produce almost all three-banded bees, and their colonies might be pronounced almost pure Italians. As there are occasionally some two-banded bees among them, we will offer them at the price of other hybrids; but at this price we can not pick out those queens having the most Italian bees. You will run your chance of getting very nearly pure Italians at these prices.

A. I. ROOT, Medina, Ohio.

HONEY COLUMN.

CITY MARKETS.

MILWAUKEE.—*Honey.*—The market here for honey is in a fair condition. Old stock getting out of sight, and value being sustained on choice qualities. Quote white 1-lb. sections, choice, 13@14; 1-lb. medium, 11@12; dark, 9@10. Extracted, bbls. and half bbls., 7@8; dark, 6@6½. —*Beeswax*, 26@31.
June 3. A. V. BISHOP, Milwaukee, Wis.

CHICAGO.—*Honey.*—Selling very slowly at present, as there is very little in 1-lb. sections on the market that is at all desirable; then the small-fruit season accompanied by hot weather, usually causes a lull in the honey-trade. The amount of honey on market is now less than at any corresponding time in 7 years. Choice brings 13@14; off, 10@12; dark, 10 —*Beeswax*, 27@28.
June 8. R. A. BURNETT, Chicago, Ill.

KANSAS CITY.—*Honey.*—The receipts of old crop of comb honey have been quite liberal the last two weeks. Demand lighter, dealers buying only case at a time. We quote: 1-lb. white comb, at 13@14; dark, 10@12. Extracted, very slow sale; white, at 5@6. Dark, at 5. —*Beeswax*, none in market.
June 4. CLEMONS, CLOON & Co.,
Kansas City, Mo.

ST. LOUIS.—*Honey.*—The season is well over on old honey, and is early for new to be ready for the market. Choice white clover, comb, 12; common to fair, 8@10. Extracted, choice, 7c; fair, 5@5½, in can. —*Beeswax*, 27@28. W. B. WESTCOTT & Co.,
June 9. St. Louis, Mo.

DETROIT.—*Honey.*—Not much desirable honey left in the market: it is selling slowly at 10@13 cts. Extracted, 7@8. —*Beeswax*, 27@28.
June 9. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.—*Honey.*—Demand for comb honey is slow, and prices nominal. There is but little on the market. Extracted honey is in good demand, and brings 5@5c on arrival, according to quality. We bought to-day the first 4000 lbs. of new choice extracted clover honey. —*Beeswax*, there is a good demand at 24@28 for good to choice yellow on arrival.
June 10. CHAS. F. MUTH & SON,
Cincinnati, O.

ST. LOUIS.—*Honey.*—We have sold the first arrival of new crop of extracted honey at 7½c. Market quiet. —*Beeswax*, prime, in demand at 27.
June 10. D. G. TUTT GROCER CO.,
St. Louis, Mo.

BOSTON.—*Honey.*—No change in prices. Honey sales very slow. We have recently received a shipment from Michigan, very fine stock, which is an ample supply for us for the summer.
June 11. BLAKE & RIPLEY, Boston, Mass.

Rheumatism * Bees.

No doubt the best bees for curing rheumatism are pure-bred Italians that prove to be good workers and work on red clover.

We have such if you want good stock to work with and to secure you plenty of honey.

Tested queens in May,	- \$1.50;	in June,	- \$1.25
Unt'd " " "	- 1.00;	3 for	- 2.50
" " " "	- .75;	3 for	- 2.00

For wholesale prices, nuclei, lbs. of bees, and all kinds of bee-supplies, write for our 16 p. circular.

Bee-Keeping for Profit

IS THE TITLE OF

Dr. Tinker's New Hand - Book.

It gives his **New System** of the management of bees complete, telling how to get the largest yields of comb and extracted honey, and make the industry of bee-keeping a profitable one. The claim is made that our old methods and appliances are of such a nature that it does not pay even the expert bee-keeper to keep bees except in very favorable localities. The New Book tells why these failures occur and how to prevent them, giving the general principles essential to a profitable system. The work should be in the hands of every progressive apiarist. It is well illustrated, and will be sent to any address postpaid for 25 cts. Please remit by postal note. Address

DR. G. L. TINKER, New Philadelphia, Ohio.

Please mention this paper. 10tfdb

A PLEA FOR MIDDLEMEN, ETC.

OUR GOOD FRIEND MUTH TELLS US SOMETHING ABOUT SELLING HONEY AT WHOLESALE.

We have seen a number of articles in bee-journals in which our friends describe the manner of disposing of their honey. Home trade is advocated every time. It has my full sympathy because it is the least expensive, and a retail price is realized; besides, we don't need that "middleman," who is looked upon with suspicion and with envy. He makes the money which the producer should make (?). All of us have seen and heard the expression of such sentiments. Our good friends are not aware of the expenses of a dealer in a large city, not even of his advertising bills, which are the least of his expenses. When one of our friends peddles his honey from house to house, and disposes of from 1000 to 10,000 lbs. in a season, he has certainly done a great deal, and I give him due credit for his energy; but he takes care of his own interests only, and he could not sell another quality of honey besides his own, if he would try to. Different men have different dispositions, and not many could do as he did. Some others have other business on hand, after the honey-season is over, and are glad to sell their honey to an honorable dealer. He takes care of his own interests also, otherwise he would not be a dealer long; but with him there is no difference between the Canada linden honey and the American basswood. It is well that this great country of ours affords a living to all; with your permission, Bro. Root, I shall endeavor to prove that the dealer also is of some use to this world.

The dealer can not, like some producers, peddle his honey, because he buys large lots, and honey of all qualities. His very existence depends on the turning of his money, and he is bound to find a

market for such quantities as come within his reach. The avocation of a dealer also requires energy and perseverance, and more so than many of our good friends have an idea of. The sale of choice clover honey has never caused us any trouble aside from the desire of selling "more." But there was a time when we did not know what to do with fall and Southern honey. We could not dispose of it at cost, and were glad to find, at last, some printing-roller makers to use our dark honey. We took care of buying no more than we could help.

Next came a time when we believed that we could dispose readily of all the honey the Southern States could produce. Vanity is not our characteristic, but we found that we had made a mistake during a time of plenty, about five or six years ago. We could not sell as fast as honey came in, by any means. But it was not so much on account of the larger arrivals, but because of the slackening of the demand from the custom which we had believed to have established. Our trade in Southern honey is now, perhaps, second to none in the country.

Basswood honey is an article which we could not dispose of until last winter, when our friend W. J. Pickard, Richland Center, Wis., sent us two carloads. It took quite an effort and some time to find buyers. But we succeeded in selling from 80,000 to 100,000 lbs. of basswood honey during the winter. We now hope that our supply won't give out, because we have established a custom for basswood honey, which we are apt to keep if we can supply regularly. Manufacturers are prone to make a uniform quality of goods.

Who is not acquainted with the horrible (?) flavor of the horsemint of Texas? The horsemint honey has been slandered. We had, last fall, a carload of horsemint from our friend Stachelhausen, Selma, Texas. For more than two months we could not

make a sale, but had returned to us two barrels from Boston, Mass., and one from Richmond, Va., and several more from nearer by. But at last we found a customer for the much-abused horsemint honey, and we could have sold several carloads more if we had had it. You would have been surprised, Bro. Root, at the fine flavor of honey-cakes made of the horrible (?) horsemint.

We had once a large customer for the fine mangrove honey of Florida. When the frost nipped the buds, three years ago, and the supply ceased, we lost that trade. Demarara sugar took the place of the mangrove honey, and we have not regained those customers yet. Horsemint eclipsed the mangrove last winter; for most of the mangrove honey purchased last fall was still on our hands two months ago, but is gone now.

From the above you see that we can't peddle our honey; but we write to our friends, see them occasionally, and post them as to different qualities, etc.

Our home trade is stimulated in a different manner. Here we see our friends also, and supply every good customer, wholesale and retail, with a fine sample case, a specimen of which will be expressed to you. It contains a dime jar, a half-pound, pound, and two-pound jar of as fine clover honey as we offer them for sale. In the upper corner of the case stands a one-pound section of comb honey. The sample case is ornamental, and, very naturally, a conspicuous place in the store is assigned to it. By it our friends and their customers are reminded of us, and we receive their orders by telephone or otherwise, if we fail to see them in time. I will send you a case, empty, for safety's sake.

We have a large trade for honey in our square glass jars, and I believe that you find our very plain labels in most parts of the country. Our square jars are popular, and I doubt whether we should be blessed with the trade we have, without them. We ordered 1000 gross of jars a few months ago, in order to buy them at old prices, and we expect to have disposed of them, filled with honey, before the beginning of next spring, not to speak of the trade we have in empty jars.

In the above I had reference to extracted honey only, which is, for us, by far the best trade. There is no breakage in transit, and losses are caused only when shippers are careless in the selection of their cooerage. We have taken, perhaps, more pains than anybody else in the country to introduce "machine-extracted honey."

Our sales of comb honey during last winter amounted to about 60,000 pounds or more. We received no full carload at any one time, but many a large shipment of most excellent quality in one and two pound sections, and in large and small shipping-cases. We received, also, our share of dark comb honey; i. e., buckwheat honey from the Northwest, and catnip from Missouri. The latter is not as dark as buckwheat, but it is dark comb honey, which is, with us, a troublesome article, if salable at all. Dealers are to blame for its production by their misleading quotations, no difference whether they were made intentionally or in a thoughtless manner. It makes me smile to see quotations of fancy and of medium buckwheat honey. We verily believe that we have as much opportunity of selling buckwheat comb honey as any one of our Eastern competitors, and we ex-

pect to sell our share hereafter. But we know that it has been, and will remain, a cause of disappointment to shippers and buyers. One may raise dark honey enough to supply his own home trade; but to raise it for shipping purposes is against his own interests. Money will be lost with almost every shipment, by at least one party, not to speak of the ill feeling created against the one or the other. We have to render into strained honey all dark comb honey on hand for a certain length of time, and after the cases have become soiled—the only thing we can do with it.

To illustrate my argument, let me give you the following problem: If we pay 5 cents for good dark extracted honey, what should we pay for dark comb honey which we have to render into strained honey? The figure must certainly be unsatisfactory to the shipper, if we want to do justice to ourselves. If we should pay him a price fair to both, our friend would accuse us of dishonesty. However, if he had sent us his honey extracted and in barrels, instead of in combs and neat shipping-cases, his product would have been three or four times the amount; and our transaction would have been pleasant and profitable to both parties. None of us would have been subjected to a pecuniary loss, and none would have been accused of being a "sharper."

Comb honey must be white, and sections well filled, when the difference is but small in the sales of one and two pound sections, although the one-pound sections will remain the most popular. We want no one-fourth pound nor one-half pound sections.

"Shipping-cases" is another item of which I wish to speak. Of the many different sizes we have received during our existence, small cases, as a rule, have proved to be the most satisfactory. All cases should be glazed, at least on one side. Cases holding 24 one-pound sections answer the purpose. We have had them arrive in two-tier sections just as safe as in one-tier. But cases holding 12 one-pound sections, as a rule, arrive safer and sell faster; and, if damaged in transit, the lot can be straightened up easier. Such is our experience. These small cases can be made of ½-inch stuff, and should not cost above 10 or 12½ cents apiece, including glass.

My article has become longer than I expected; but other business does not allow me much time, otherwise we should perhaps write shorter letters and oftener.

CHAS. F. MUTH.

Cincinnati, O., May, 1890.

Friend M., I am exceedingly glad to get the above paper from you. It always gives me pain when I hear folks uttering wholesale condemnation and complaint against any class of people—that is, people who are engaged in an honorable employment. We have had some experience in selling honey by the carload, but not very much, however, compared to what you have had. But we can fully understand that it requires a man with special ability, and that it is a trade of itself. I congratulate you on the success you have made in introducing honey from special localities. We have had trouble with buckwheat honey, similar to yours. Quite a lot of it is now burdening our shelves. Yesterday the bees made their way in, evidently thinking that, if nobody else wanted it, they could dispose of it to good advantage. Our wagon is offering it at 10 cents a

pound retail, and carrying it to the houses; and even at that price it does not sell. We do not wonder that you had such success with Mrs. Pickard's honey, from Richland Center, Wis. I was present when they were taking it out, and I thought that their basswood honey compared favorably with any honey in the world. If basswood is thoroughly ripened, and is thick, and has no taint nor fermentation, it is, in my opinion, luscious. You know something about having honey returned, as well as ourselves. There is quite a tract of country down in Kentucky and Virginia where the merchants will return every bit of honey as soon as it candies. They say it turns to sugar, and is useless; and during the past winter we have exhausted our logic in trying to convince them that it was all right. Our good friend Capehart, who took the orders, insisted that honey must be melted, and shipped away hot—or, at least, that is pretty nearly what he said. Well, so long as it remained liquid it sold very well; but when a cold wave came, then there came a wail from honey-dealers. I felt as if I should like to get the whole of them together and shake some sense into their heads. Now, friend M., if you can sell honey down there, and explain by circular or by personal letters that candying is not a plain indication of fraud, I shall be glad to have you undertake it. Where bee-keepers like the business of peddling honey, and can dispose of their crop in that way, by all means let them do so; but it certainly is a great piece of folly to find fault with commission men and middlemen indiscriminately. Why, friend M., if it had not been for you and your sturdy energy in working off the product of Texas, Florida, Mississippi, and other like localities, I do not know where our honey business would be just now; and it was news to me to learn that you had made an opening for the great basswood product from Wisconsin. Go on, and don't feel hurt, even if some of our small fry say unwise things occasionally.

DEEP SPACE UNDER FRAMES, ETC.

NOT A SUCCESS.

My experiment in trying to have a deep space under brood-frames through the summer has already come to grief. April 30 I found some comb started under the bottom-bars, and in one case a piece of drone comb, some 8 inches long, built clear down and filled with drone eggs. It was all built of old black wax. Others have succeeded; what causes my failure? My bottom-bars are $\frac{3}{4}$ wide and $\frac{1}{4}$ thick. Perhaps a wider or thicker bottom-bar is needed. If top-bars can be so made that bees will not run comb above them, can not end-bars and bottom-bars be so made as to prevent combs between them? They are certainly less inclined to build comb there than between top-bars. If, however, bottom-bars are made wide, there will certainly be much trouble in having them glued together; for my $\frac{3}{4}$ bottom-bars sometimes touch and are glued together. I need not say what an annoyance it is to attempt to pull out a frame and find it holding fast to the bottom-bar of the next

frame. It is just possible that, in spite of my strong and long feeling against fixed distances, I may think it worth while to try the experiment of a wide frame in all its parts, with spaces at each corner. In any case I want the deep space under the frames in winter, and, if necessary, I will in some way lessen the space in summer.

FLAT COVERS.

Another thing that has not worked as well as I expected is the flat hive-cover. Either the hive or the cover, in too many cases, is just a little out of true, and that lets in cold air in spring. Is there any remedy for this? If I can not do any better I can put quilts or cloths on.

SAGGING OF TOP-BARS.

While I am telling my shortcomings, I may as well speak of top-bars. I have always said that I had no trouble with $\frac{3}{4}$ top-bars sagging, although wired without any diagonal wires. This spring I hoed all the brace-combs and propolis off my top-bars for the first time in three or four years, hoping to get the honey-boards to work as well as ever, and I found some places where there was sag enough to make a space of $\frac{1}{2}$ inch between top-bars and cover, instead of $\frac{3}{4}$, as designed. I believe I would rather have top-bars so thick that no sagging need be feared. My top-bars are all an inch wide, except in the few Dovetailed hives I have. These last are $\frac{3}{4}$ wide, and they sagged worse than those 1 inch wide. I think hereafter I shall clean off the tops of my frames every year, as I formerly did.

KEENEY'S PLAN OF WIRING.

I've tried hard to find some fault with the plan, taken with Ernest's improvement on page 372, but I can't do it. If foundation is cut a little too large, so as to be crowded down on the bottom-bar, I don't believe there will be any need of reversing to get combs built down. I can readily believe that $\frac{3}{4}$ top-bars will not sag with this plan, since so few of my $\frac{3}{4}$ top-bars sag with perpendicular wiring without any diagonals. But my bottom-bars, being $\frac{3}{4} \times \frac{1}{4}$, do sag—upward.

ARRANGEMENT OF HIVES.

The lay of the land has much to do with it. In one of my apiaries I have, for the last two years, used a combination of friend Hatch's plan, on page 374, and Ernest's plan on the next page. Perhaps I might say it is simply the first part of Ernest's plan. I like it better than any thing else I ever

tried. Possibly I might like the Hatch plan better; but as there need be only 6 inches space between the hives in each group, I can, without using any more space, have an alley $15\frac{1}{2}$ ft. wide where friend Hatch has 10 feet. If space is important, or if it is desired to have the apiary as compact as possible, my plan is better; but then flying bees will trouble more. Where there is no objection to using a large space, friend Hatch's plan is hard to improve on; and if it be desirable to have them closer, the 6 feet between hives, where they face each other, can be reduced to two or three, and the alleys made narrower. Just now my assistant objects to having

the hives facing each other any nearer than six feet; indeed, she objects to their being as near as six feet, in case of swarming. Another thing comes to me that I had not thought of at first. Friend Hatch has less trouble with flying bees in his alleys; but how is it when he is working at a hive? If he sits at the middle of the hive he is just 7 feet in front of a hive, nearly in its line of flight. With my plan, and the same number of hives on the ground, I am 16 feet away from any hive which is facing me. As I spend more time at the hives than I do in the alleys, I believe I like my plan best.

Marengo, Ill., May 20.

C. C. MILLER.

I am somewhat surprised, friend M., that the deep space under the frames has already proven a failure with you. Our good friend Baldrige and one or two others claim them to be a success. Our friend Danzenbaker gives $\frac{3}{4}$ inch under his brood-frames, and has, in connection thereto, an entrance $\frac{3}{4}$ deep, or wide. Mr. D. says that he not only finds nothing is built under the bottom-bars, but that this extra space with a wide entrance forces the bees to enter the supers a little earlier. He argued that bees are anxious to get their stores as far away as possible from the cold and robbers; and if the bottom of the hive were open, or exposed by a wide large entrance, the bees will actually carry their stores where it is close and protected. But if I understand you, your experience doesn't corroborate this, for you have a large entrance.

Now, doctor, I have just been waiting for a good chance to quarrel again with you on your manner of cleating covers. You know I argued, a while ago, that the covers should be let into *grooves* of the cleat, and nailed. You thought that a cleat simply nailed on to the ends of the cover, without grooving, would be just as strong, and better. And now you say your covers are not always true. I have never yet seen one cover of the Dovetailed hive that warped any; and if the Dovetailed hive is nailed true, the hive can not get out of true, on account of the great strength of the corners. Practical tests in the apiary prove this. I feel quite sure, doctor, that a cover-board let into a *groove* in a cleat is much less liable to warp than one dependent on nails alone. In this connection, perhaps I should say that flat covers covered with tin are liable to warp or wind. I notice that quite a number of our customers are ordering these covers with the tin. They will regret it, I feel sure, and for this reason: The upper surface of the board, immediately under the tin, is kept dry; the under surface, next to the bees, is subject to more or less moisture from the cluster. A cover-board not protected by tin receives the moisture from the dew and the rains on its upper surface, and this counterbalances the moisture on its under side. I should be glad to have any one try the experiment with the tinned and untinned *flat* covers, and report. I do not know, doctor, whether you cover with tin or not, but I presume you do not.—I think I can indorse all you say in regard to the sagging of top-bars. I have seen them bend down fully half an inch from a straight line.—I am glad you can not find any fault

with Keeney's plan of wiring. I hope you will try it this season, and report to us a little later.—In regard to the arrangement of hives, the lay of the land certainly has very much to do with it. Trees, stumps, and uneven places, very materially modify any nicely proposed plan that we may have. When we located our basswood apiary we arranged a plan. The ground was a little swampy and uneven in places, and we found ourselves obliged to put the hives just where they will stand level, irrespective of any well-defined plan.

ERNEST.

In addition to the above, friend M., I wish to suggest that a Simplicity cover is made exactly to keep the cold spring air out; and yet you are all going to throw it away, without even a thought of its advantages. Yes, and you coolly ask if there is no remedy for your flat tops and covers; and then, after I gave you the diagonal wires and tin bars that make an absolutely sure thing against sagging, you forgot all about that.

BRACE-COMBS AND BURR-COMBS.

HOW TO PREVENT THEM; ALL IN SPACING, AND NOT IN WIDTH OR THICKNESS OF BEES.

THE following is a private note received from one of our Canadian friends, which will explain itself:

Friend Root:—

Inclosed please find a paper written and read by request of the Oxford Bee-keepers' Association, at Woodstock, on the 21st inst. I think the paper will be helpful by directing attention, especially to the importance of proper bee-spaces. It is the *space* that must be right, regardless of either width or depth of top-bar. A top-bar $\frac{1}{2}$ in. thick only, is, in my opinion, just as safe against burr-combs and brace-combs, provided the spaces be right, as one an inch thicker. A few years ago this same subject was up. I said to my wife that I had a mind to propose to Mr. Root that he visit me; and that if he did not fully agree that the remedy was all in the spacing, after looking over my hives, I would pay all expenses of the trip; but after thinking awhile, she replied, "Oh! well, you know people see things so differently that all might not be satisfactory." So I dropped the matter. I shall not feel hurt if you think the paper of no use, and drop it in the waste-basket.

S. T. PETTIT.

Belmont, Ont., Can., May 27.

The following is the paper:

In all improperly constructed, occupied hives, may be found, in addition to the orthodox brood and drone combs, two other kinds; viz., brace-combs and burr-combs. Now, in order to get rid of, or, more properly, to prevent, the building of the troublesome brace and burr combs, it would be well to inquire into the cause of their construction, or into the conditions most favorable to their construction; or, in other words, why they are built. The brace-comb (if it may be called a comb) is intended for a very different purpose from that of the burr-comb. The former is constructed in position for just what its name implies—a *brace*; and the latter ultimately for store combs. If during a good honey-flow some sealed honey be placed close

together than the bees placed it, they become alarmed; and to prevent more crowding, and to keep things in position, they go to work and build *brace-combs* in the now too small bee-spaces. Upon examination, brace-combs will be found to be studs of hard wax, with, in some cases, a touch of propolis, possessing no small degree of resisting power. Brace-combs will usually also be built in all undersized bee-spaces, so the cause of their presence in almost all cases is quite apparent.

With regard to burr-combs, if we investigate the matter we shall discover the reason why the wayward little workers do so persistently persist in building them. We all know, I presume, that bees are severe economists, and most exacting in that line. They economize heat, time, and every thing pertaining to their welfare. Every available particle of sweets, and every thing that can be utilized by them, is eagerly gathered and stored; but in nothing are they more economical than in the space inclosed within the walls of their domicile. It is their inherent nature to occupy and utilize every space, larger than a bee-space, within their homes; and especially so is this the case at or near the top of the brood-chamber; and now, just at this point, I would ask, Is not the cause of the presence of burr-combs apparent? and does not the remedy readily suggest itself? My experience, running over quite a number of years, says the cure is at our finger-ends; is easily understood, is unpatented, and may be had for the taking—simply adjust all the interior parts of the hive so that a proper bee-space is maintained throughout, and the goal is reached—the joy is yours; for under these conditions there is neither room for burr-combs nor supposed necessity for brace-combs, and but very few of either will be built.

Frames are spaced by different parties, all the way from $1\frac{1}{4}$ in. to $1\frac{1}{2}$ in. from center to center, so it will easily be seen that, in order to form proper bee-spaces, top-bars must be of different widths, according to the spacing practiced.

Top-bars $\frac{3}{4}$ in. square, and spaced $1\frac{1}{4}$ in. from center to center, will form spaces $\frac{1}{2}$ in. by $\frac{3}{4}$ in.; and he who expects that bees will not economize such roomy spaces at the top of the brood-chamber has failed to note one very prominent and important characteristic in bee-nature, and will simply be disappointed. Like noxious weeds, his crop of burr-combs will grow until these spaces are nearly full, and super ventilation well nigh chopped off.

But, what about deep top-bars? will one inch or so of depth prevent burr-combs between top-bar and super? Well, now, I am aware that this point should be approached charily, as so many experienced bee-keepers regard depth of top-bar as having great virtue in that line; but with all due respect for the opinions of others, I will frankly state that, after six or eight years of experience with thick and thin top-bars, I am pretty well convinced that that virtue is not in depth of top-bar, but in *correct spacing*.

Although my real frame has a top-bar about $\frac{1}{2}$ in. thick, my ideal frame has one only $\frac{1}{8}$ of an inch in depth, and of the necessary width to form correct bee-spaces. Most bee-keepers, I believe, regard $\frac{1}{8}$ of an inch as *the* bee-space. Well, I will not quarrel with that, for it is worthy of notice that the bees themselves, as yet, are not fully agreed as to what a proper bee-space should be; but I would add that it must not be even a shade more than $\frac{1}{8}$ of an

inch—anywhere between $\frac{3}{32}$ and $\frac{1}{8}$ will do; but between top-bars and supers, $\frac{3}{32}$ of an inch has my decided preference. The top-half of end-bars should be of the same width as the top-bars, and the lower half tapered down to the width of the bottom-bar. The end-bars of my frames are all so made now. In all fairness, it should be admitted that some stocks seem to have a peculiar fondness for burr-combs; and under almost any conditions some embryos will appear in the hives of such bees.

Belmont, Ont., Can., May 20.

S. T. PETTIT.

Friend P., I have always been greatly averse to thick top-bars, for the reasons you have given. It curtails too much the space we should like to have filled with brood. When the diagonal wires and tin bars were invented, I thought I had solved the great problem by enabling us to use thin top-bars, leaving so much additional space for brood, and at the same time having no sagging. I should be very glad indeed to know you are right in your deductions; but, if I am correct, a great many will not agree with you—at least not until they have gone over the ground carefully and made more experiments. Give my respects to your good wife, and tell her I have long been thinking of making you a call, and that it will not need the additional incentive of having my expenses paid, to bring it about. And now about the bee-space. In our locality it is a very difficult matter to maintain an exact bee-space. I find that old hives in our yard will shrink and swell, under the influence of the weather, $\frac{1}{8}$ inch; and as the frames rest on the rabbets, near the top edge of the hive, this must of necessity vary the bee-space between the upper and lower set of frames. We made some hives two years ago that were just exactly $9\frac{1}{4}$ inches deep. As the L. frame is $9\frac{1}{2}$ inches deep, this would leave $\frac{1}{4}$ inch bee-space on top of the frames. Well, last spring I measured these same hives. Instead of shrinking $\frac{1}{8}$ inch, as I thought they would do, they had actually swelled so that they were $9\frac{3}{4}$ deep. It is quite dry weather now, and their present depth is $9\frac{1}{2}$ inches. I have just measured several of them. If we should have continued dry weather, they might possibly shrink another sixteenth. I must confess that I am very greatly surprised to note the different depths of hives, due to climatic conditions. This may not be true in all localities, but I should feel pretty sure that it would be in most of the Northern States. Now, then, the point comes up, How are we here in Medina, and a good many other places, going to maintain an absolute bee-space, so it shall be the same at all times? I confess I do not know. The question arises, "Is it necessary to have an absolute bee-space, at all times of the year?" It does not matter much if we do have, in the spring and fall or winter, $\frac{3}{8}$ or even $\frac{1}{2}$ inch; but when honey is coming in, and brace-combs naturally start, then is the time we need pretty nearly $\frac{1}{8}$ bee-space; and if the hives are made right we will get it providing the weather is dry. Our new Dovetailed hive allows a bee-space of exactly $\frac{1}{8}$ between the brood-frames and sections. As the sections are supported by flat tins on the bottom edges of the super, a little shrinkage

or swelling will not affect the space between the brood-frames and sections. It is a comparatively easy matter to control bee-spaces between *shallow* supers, and between super and brood-nest; but between an upper and lower set of brood-frames, *L. depth*, it may not always be uniform. There will be a small variation between a dry and a wet season, with us. Your logic is good in regard to exact bee-spaces; and in localities where they can be maintained uniformly, perhaps a thin top-bar will answer; but with us I fancy we shall need the additional assistance of a deeper and wider top-bar. This is a splendid field for experiment, and I hope many of the readers will test it carefully.

MOVING BEES.

THE TWINE METHOD OF FASTENING HIVES; A BIG TESTIMONIAL FOR IT.

I have just returned from moving 40 colonies of bees with an ordinary farm wagon, without springs, over quite a rough road, some 8 miles, to an out-apiary, with more ease and expedition than I ever did before (and I have moved many hundred colonies, and used all sorts and methods of fastening). I used the twine fastened as given by Ernest, on page 252, April 1; and though exceedingly busy I write this to let some one who has bees yet to move, know that the method is a decided success, if ordinary precautions are used, and common sense exercised. I hauled 20 at a load, and with each colony in an old-style Heddon hive. I used two half-story supers filled with sections and starters, which made it more difficult to fasten, and more cumbersome to handle than single bodies would have been. The bottoms were all loose—nothing nailed or fastened, except by the cord, which was about the size of an ordinary clothes-line. I took the precaution, however, to secure the two parts, where they come close together on the top, by a smaller piece of twine, so as to prevent all possibility of slipping. To enumerate the advantages of this method, I will say that time and temper are saved in preparing the colonies for shipment; no nails to mar or split cover, hives, or bottom, and they can be undone in one-fourth the time it usually takes by any of the old methods. Thanks are due to the editor of *GLEANINGS* for giving those of us who must move our colonies to out-apiaries for so great an improvement, say I, and all will join me who try it.

Belleville, Ill., June 2.

E. T. FLANAGAN.

Yes, sir, friend Flanagan, you are right. The twine method of fastening hives for moving bees is rapid, cheap, and, with ordinary care, safe. No little thing like this ever gave me more real pleasure to give to the bee-keeping world than this, because I knew it was good. Our Mr. Ward, the teamster, invented the plan. I hope our readers who have any thing to do with moving bees will give the plan a trial. I have explained it to our packers, and they are actually sending out hives, for short distances, by freight and express, tied by this plan, with no crating whatever. For particulars, see page 252, April 1.

MAKING THE BEST OF EVERY THING.

HOW TO GET ALONG; WHAT TO DO WITH DISAPPOINTMENTS, ACCIDENTS, AND STUMBLING-BLOCKS.

Friend Root:—The Barnes saw that I ordered of you the 12th of this month came to Concord yesterday evening, so I took a spring wagon and went after it this evening, and brought it home, and thought I would set it up to-night; but after opening the box I found the arm, or support, that the journal of the fly-wheel rests on, was broken in three pieces, and one end of the mandrel was sprung—done in shipping, for I heard those pieces rattling when the railroad men rolled it out of the freight-room. Now, I shall have to get a new support for the fly-wheel, and a new mandrel, before I can use the mill. I think the company ought to send them free, and I will leave it to you to fix the matter with them; but have them sent immediately, and I will do whatever you say, for I have confidence enough in you to believe that you will do just the best you can under the circumstances.

Poplar Flat, Ky., May 27.

L. C. CALVERT.

Later, May 31.—Well, friend Root, my mill coming in the shape it did gave me the blues, and I could not help it; but I never went to sleep after going to bed until I made up my mind to try my saw next morning, so I got up early and went to putting it together. I took a strip of plank and laid the broken arm on it, and very carefully put the pieces (for it was broken in three pieces) together, and marked it off and cut a bed in the wood for it, and then screwed a block over it, and put the mill up and tried it, and it ran all right. Now for the mandrel. I put the crooked end in its box, and screwed the box fast in my bench-vise, then made a gauge fast to the bench, and turned the mandrel until it came to the point where it was furthest from the gauge; then I carefully sprung it and kept on until I could turn it clear round, and it would just touch the gauge all the time. I put it in and started the mill, and you ought to have seen the blues go out at the back door of the shop. I ran the mill the rest of that day, and Thursday and part of Friday, and it has cut over 2000 feet, line measure, and now I feel as if I were almost fixed for running a hive-factory. I can say that the mill will do all that it is recommended to do, and I am well pleased. But that broken arm, or support, for the fly-wheel, I want sent, but I am in no hurry for it. Any time will do. I think it could be sent by mail about as cheap as any way, as it is not very heavy. As you stand to operate the mill, it is the left-hand side that the broken piece is on.

L. C. C.

Well done, my good friend C. How many times in my daily travels about the grounds and the factory I find things come to a dead standstill by some break-down, disappointment, or mishap! Very often, time enough is spent in severely censuring, to have gone to work and started things going again. I have before written in regard to people who have a knack of mending things. Oh what a need there is in this world for people who are good at patching up broken tools and machinery! It is true, in the above case, that the fault lay either with the shipper or transportation companies, or both; and I have known people to refuse to take a thing from the depot because

of some trifling injury. Within a month a lot of basswood-trees were refused because the tops had been bruised by standing them up in the car; therefore they were left at the station, to dry up and spoil. Now, I have had large experience with railroad companies and manufacturers, and business men almost all over the world; and with few and rare exceptions my advice is, to take your goods and pay charges. If there is an overcharge, call your agent to witness the state of affairs. If the goods are damaged or broken, do the same. Then take your goods and repair the mischief as well as you can. Make out your bill for damages and trouble, in a fair and Christianlike way. Present the matter as an honest man should, and write to the faulty ones as you would write or speak to honest Christian men. To the railroad companies I often say, "Now, friends, the above are the facts as nearly as I can give them. If you see fit to pay me for my trouble, I shall be very thankful; but if you do not, I shall shoulder it as best I can, and try not to have any hard feelings." Such a letter almost always brings liberal treatment. And it is the same way with a manufacturer or dealer. A mild or pleasant letter to begin with will certainly do no harm. If it should transpire, however, that you have been duped and swindled by somebody who has no thought of making the matter good, then, but not before then, is the time to bring forward your artillery and fight for your rights. I am well acquainted with the manufacturers of the Barnes saws; and if they do not, in answer to the above, treat our friend Calvert handsomely, then I shall be mistaken. I have thought sometimes that they erred on the side of too much charity. In our work, all ordinary breaks in machinery are carried to the blacksmith. Very often, however, where a casting is broken there is no way but to send to the maker for a new piece. Frequently, however, we can hold the broken pieces together by a little ingenuity, so as to use the implement or tool until the missing part comes.

FIVE-BANDED ITALIANS, ETC.

PROF. COOK GIVES US SOME FACTS.

MR. JACOB T. TIMPE, Grand Ledge, Michigan, sends me some bees which he requests me to examine and give my opinion, through GLEANINGS, as to the number of bands, and as to their race or blood. These are, I believe, five-banded Italians. They are very yellow and very beautiful. The five bands are so plainly shown that no one could fail to discover them. Mr. Timpe asks if I should suspect them to be in any sense Cyprians, or that they might have any Cyprian blood in them. I think not. I think they are Italians. I have often seen these very yellow Italian bees. I believe I could take any Italian bees, and, by breeding with color alone in view, I could very soon get four or five banded bees. It is as easy to breed for the yellow as the white, which latter gives us the "albinos." I have no doubt but these bees are five-banded Italians. I should expect them to be very gentle, as they are very beautiful.

HERMAPHRODITE BEE.

Mr. Timpe also sends me a very interesting bee. I am much interested in such specimens. They are very curious, and show that the bee-keeper is a close observer, to detect the freak. This bee has the eyes and mouth organs of a drone, the antennæ of a worker, as to number of joints—twelve; one antenna the form of a worker, the other a drone, the body and wings of a worker, a sting, while the legs on one side are like those of a worker, while those on the other are regular drone legs. I have seen but one other case of equal interest. In that, one side is drone, the other worker, as I reported at the time in GLEANINGS.

NEW YORK WEEVILS.

Mr. A. Troxel, Nankin, Ohio, wishes to know through GLEANINGS the names and habits of two large gray beetles which he has sent me. These are weevils, as is at once evident by their long snout. This is the New York weevil, *Ithycerus noveboracensis*. It is one of our largest weevils. One of these is two cm., or .8 of an inch, long, though it is very large, even for this species. They often eat into the branches of apple-trees, and so girdle the twigs. If they were very numerous they would do much damage; but as they have been well known for years, and have never been so numerous as to cause alarm, I think we need not greatly fear them.

TACHINA FLIES.

If any one will look at page 424, Fig. 214, of the 14th thousand of my Manual he will see the figure of a tachina fly. These flies closely resemble a house-fly, to which they are closely related. They lay their eggs on other insects, bees included. The maggots that come from these eggs bore into the victimized insect, and wax fat at its expense. Thus the victim becomes at the same time food and home for the parasite. In most cases this tachina fly does great good, as it destroys hosts of our worst insect-pests. But when they attack bees, and kill them, it becomes quite another matter; then they are our enemies, not our friends.

It is one of these tachina flies, without doubt, that is destroying the bees of Mr. J. S. Lummitt, Bakehill, Tenn. He says the bees lie about the hive dead, and, when examined, he finds the maggot inside. This is just as I have always found this parasite, so I have no doubt but that I have decided correctly in this case. I have written to Mr. L. for specimens of the lately dead bees. As soon as I get them I will rear the flies and then I will illustrate and describe the species that is doing the mischief in Mr. L.'s apiary.

THE CEREALS AND GRASSES NOT HONEY-PLANTS.

In reply to the query of Prof. B. F. Koons, let me say that I have never seen bees working on any of our cereals—wheat, oats, barley, or rye—nor on any of our grasses, for either honey or pollen. So in answer to his question: "Do bees work on wheat, rye, oats, or grasses, either for honey or pollen, and thereby bear an important part in the fertilization of such plants?" I answer, unhesitatingly, no. Dr. W. J. Beal (see his valuable work on grasses, Vol. I.) states that he has repeatedly seen honey-bees working for pollen early in the day on tall meadow fescue (*Festuca arundinacea*). He says the flowers of most grasses, except where close fertilized, are usually anemophilous; that is, fertilized by the aid of the wind. Without doubt, insects do

not serve to cross-fertilize many of the grasses. Tall meadow fescue and buffalo grass may form exceptions.

In case of the cereals, all except rye, perhaps, are close fertilized, and thus our observation—not seeing the bees on the plants—and also the structure of the flowers, alike prove that bees take no part in their fertilization.

We may, it is true, see bees working on both the cereals and the grasses. In such cases we shall generally find plant-lice on the grass or grain, and the bees are after the nectar secreted by the insects. In case of ergotized grain or grasses—those bearing ergot—we may find bees swarming on them, as this fungus secretes a nectar which is very attractive to bees. So the mere seeing of bees around grass or grain is not conclusive that they are in quest of pollen. We must examine closely, when usually we shall find the nectar-secreting aphides or ergot.

In conclusion we may say that, while bees do act as very important aids in fertilizing nearly all our plants and vegetables—nearly all with showy or odorous flowers, they do not thus minister to the welfare of the grasses or cereals.

BEE-MITES.

It is never quite safe to diagnose a case till you have seen the patient; but I have no doubt that the small "mites" which are vexing Mr. S. R. Morris, Bloomington, O., are mites. Very likely they are the same that I have illustrated in "Bee-Keeper's Guide," 13th edition, page 430. These little eight-legged mites are soft, so that when slightly pressed they will be crushed and leave a red stain. Mr. M. asks how they can be destroyed, or how he can get rid of them, as he regards them as even worse than ants. As I have never had a chance to experiment, I can only suggest. I would propose that a wire gauze screen be put above the bees, so as to keep them away and then place cloth or paper, with some sticky substance on it, for the mites to attack. They will stick and so can be cleaned out. The sticky fly-paper might be used. If it does not work—I think it would—try greased paper—paper smeared with lard or molasses. The wire keeps the bees away, while the smaller mites pass through to the adhesive paste, and are caught. A screen cover and all could be rigged for a single hive, and, if successful, it could be used on the hives successively till all are freed.

THE SKINKS.

Mr. C. E. Hardesty, Connotton, O., sends me a small skink which he wishes me to comment upon for GLEANINGS. This is one of the lizards, or swifts. The Skink family have broad heads. This one is bright orange, prettily marked with black dots. It is too small and young for me to name. The lizards, swifts, or skinks, have four legs, long tails, and can run very rapidly, hence the common name, swifts. Like the joint-snake, or glass snake—really no snake at all, but the joint or glass lizard—already described in GLEANINGS, which, as will be remembered, though a lizard, has no legs, these swifts are loosely joined at the vertebrae, so that the tail breaks off very easily. Some of the skinks are very pretty, and are worthy to be admired, if people would drop their prejudice and not frown upon every thing that creeps or crawls.

The dread felt for lizards is entirely groundless. They are as safe to handle as kittens, and may be fondled as fearlessly, as they can do no one any

harm. The skinks feed on insects and other small animals, and are not in any way harmful.

A. J. Cook.

Agricultural College, Mich., June 6.

Why, old friend, is it indeed true that lizards are harmless? I have often admired their bright little eyes, and felt like patting them on the back; but it is entirely new to me that they may be fondled as fearlessly as kittens. Now, why in the world don't you have a museum of pet lizards? You might have it somewhere in the neighborhood of that pet bear. By the way, give my respects to his bearship, accompanied with a bottle of honey, and charge the honey to the account of A. I. Root.

LUTHER'S SWARMING-IMPLEMENTS.

THE FOUNTAIN-PUMP.

I have used a set of swarming-tools three years, and I think them very good. I can take down swarms that have clustered high or low in trees. I can stand on the ground and get a swarm that is 20 ft. high, or I can go up 20 feet on my ladder and get them if they are 38 feet from the ground. I use an extension ladder, each section 12 ft. long, and two basswood poles, each 16 ft. long. No. 1 is $\frac{3}{4}$ in.

square, with a board 2x8, hollowed at the ends, to form a hook, when the pole is nailed to the edge of it. The end of the board is to be 8 inches from the end of the pole. No. 2 is $1\frac{1}{2}$ x $1\frac{1}{2}$ in., with the face of the pulley toward the basket. There is a cord 25 ft. long, with a snap at one end, also a small staple driven into the pole about 11 ft. from the pulley to hook the snap into when not attached to the swarming-basket. The pulley is a common window-frame pulley, put in near the end of the pole, the same as is put in a window-frame.

The way I fix my baskets, I take a No. 10 wire, bend it in the form of a bail, and put the ends through the rim of the basket and bend the lower

end to the hook around a splint. The handle needs to be 12 or 15 in. above the top of the basket. I have a string 2 ft. long hanging at the bottom of the basket, to take hold of to shake the bees out. I use a small market-basket 12 in. long, 8 wide, and 6 deep. I think they cluster on it better than on peach-baskets. I also have hooks made of heavy wire, to hook over limbs to hang up baskets with bees in, to wait until I can get time to run them into the hives. The way I manage is this:

As soon as a swarm has gathered on a tree, I go with my basket and poles, hang pole No. 1 on a limb where I can easily reach it when wanted (see drawing). Pole No. 2 I hold so as to get the basket close up to the bees; let it lean against the limb, when I hold cord and pole with left hand, then take the small pole in my right hand, and, placing the upper end against the limb the bees are on, give the pole a quick shove up, striking the hook against the limb. I then lower or swing the basket 2 or 3 ft., and wait until most of the bees have settled on the basket, after which I let the basket down so I can take hold of the bail, and unhook the snap.

I now take a look over the apiary, to see if there are any swarms in the air. If there are, I hang the basket of bees in the shade, to wait until convenient to care for them. If there are more than one swarm in the air at once, I use the force-pump to keep them separate; and as soon as one clusters on a limb, I proceed as before with baskets and poles until all are in the baskets, then run them into the hives.

I had 24 colonies last year, and three baskets were as many as I had in use at any one time. I inclose a drawing of my device, made by Master Frank M. Silverthorn, one of my neighbors, who has taken but 8 lessons in the art, of a teacher. He is also somewhat interested in bee-keeping.

STEPHEN LUTHER.

Fairview, Pa., March 4, 1893.

DISADVANTAGES OF FIXED FRAMES.

DR. MILLER MILLER DISCUSSES THE PLAN PRO
AND CON.

SHALL we ever get any thing settled—settled to stay? No sooner do we get settled down upon any thing than some one stirs it all up again. And now comes Ernest with his "fixed distances;" and when he starts on a thing he's such an intense chap! He's so Ernest! But, why doesn't he spell his name one way or the other—either Ernst, in German, or the English translation, Earnest?

But, about the "fixed distances," Ernest, don't you know that, when you were wearing short pants, it was pretty generally settled that we didn't want the inconvenience of fixed frames? There are still in use, if I mistake not, in that country from which you get your name, hives that open at the side, allowing the first frame to be pulled out sidewise with a hook, then the next, and so on, obliging you to take out every frame if you want to get the last one. The closed frame, as in the American, was an improvement on this, for you could get at the frames from the top; and after taking out the first frame you could move the others along to get out any one you wished. But that movable side wasn't liked as well as a solid box, and it was so much nicer to be able to lift out any frame you wished, simply by moving the others a little to one side. You were

started on this tack by the need of something to keep frames fixed when hauling to and from out-apiaries. But I have never felt the need of this. I haul my bees home in the fall, with no other fastening than that which the bees have made, and haul them back in the spring the same way. In fact, I expect to haul my bees to the out-apiaries this spring without taking off a cover, from the time they were hauled home last fall. I wondered at your saying, on page 99, that you had so much trouble hauling, till I remembered that you had $\frac{3}{4}$ top-bars. Mine are one inch, and I believe there is a great difference in the stability of the two. Yours will swing with a good deal less shake than mine; and if we are to have wide top-bars, perhaps you will not be so anxious for the staples or any other toggery of that kind. But you say I am prejudiced. I suppose I am. I've always had loose frames, and never handled any others except once, and then I didn't like them. But your earnestness in the matter, and your lugging around those spacing arrangements with you at the Ohio convention, have made me do some thinking, and I'll try to talk fairly about

SOME ADVANTAGES OF FIXED FRAMES.

I must admit, that it is a nice thing to have frames so fixed that there is no kind of danger that they will get out of place in hauling or handling, that you can pick up an empty hive and carelessly set it down where you want to have a swarm without having to stop and arrange all the spacing. Then, too, if you could have it without the attendant disadvantages, and without too much trouble and expense, it would be nice to have your frames so that you can instantly and certainly space them just at the distance you want them. It takes time to space with the fingers. After you have put in all your frames, spacing them as you go, you find you have a quarter or half an inch more in the last space than you want, and then all must be readjusted. And then if we are to do without honey-boards, and depend upon spacing a certain distance, say $\frac{1}{8}$ in, I suppose that $\frac{1}{8}$ in must be *exact*. If you spend 15 minutes in spacing loose frames with your fingers, I don't know that you can get $\frac{1}{8}$ in exact—certainly not so exact as you can by instantly pushing them up against some spacing arrangement which allows them to go just so far and no further. With such an arrangement there is not the same chance for mistake or carelessness. More than once I have found two frames spaced apart twice as far as they should be, or pinched up together till almost touching. Such things could not be when frames are forced to be just right if got into the hive at all.

All these things considered, especially if we must have *exact* spacing, it may be well enough to re-try some spacing-device—I don't mean settle positively upon it, but give it a fair trial. So it may be well enough to ask in advance,

WHAT SPACER SHALL WE TRY?

Some of them are too much like the closed end-bars, requiring a movable side. And now I may as well confess that, for several years, I have been using what is practically a side-opening hive. I used eight brood-frames in a ten-frame hive, with a division-board at the side; and to all intents and purposes that made it a side-opening hive. Then when I changed my ten-frame hives last year to eight-frame, I made them 12 $\frac{1}{2}$ wide inside, to correspond with my supers. Spacing the top-bars 1 $\frac{1}{2}$ from center to center left a space of 1 $\frac{1}{2}$ inch at one side,

and this I filled up with a dummy. So you see I was in a measure forced into it; but I have found my present arrangement so very convenient that, if I were commencing every thing anew, I would make an eight-frame hive $12\frac{1}{2}$ inches wide, and put in a dummy $\frac{3}{8}$ thick. One special advantage is, that by taking out this dummy I can move the frames along and handle any one I wish, without setting a frame on the ground to let me get at the rest. But I should not want a closed-end frame—at least, I think I shouldn't. I think we want a spacer that, when a frame is lifted a quarter of an inch, it will leave the frame just as free as if there were no spacer in the hive. I don't like Phelps' staples, but I do like his hemispherical-headed brass furniture-nails better than any thing else I have seen. They must work smoothly. There can't be any catching about them. They are easily put on any frame, even without shaking off the bees. They are the least likely to dull an uncapping-knife. I don't know just how much should be conceded to the uncapping-knife. Comb-honey men need not consider it, neither need extracting men, if they do not extract from brood-frames, and I think brood-frames are extracted less and less.

Now, if you don't find something better, get some of the right size of these furniture-nails, tell us how you will sell them, together with a push-stick made just right to push them in, and a good many of us may want to give the Phelps plan a fair trial.

Marengo, Ill., Mar. 21.

C. C. MILLER.

Friend M., don't lay the present fixed-distance bubble to me. If it should burst perhaps I shouldn't want to father it. Yes, doctor, there was a time when I wore short pants, when there was an old Quinby closed-end hive in one corner of the apiary. I was afraid of bees in those days, and, of course, had no practical knowledge of the terrors of fixed distances as found in Quinby frames. But things are changing a little bit now. As I have before said, out-apiaries have necessitated some sort of frame that is better for moving bees; and it is very natural to look to fixed distances to help us out. Another consideration comes in; and that is, there are very few bee-keepers who space their frames properly. Farmer bee-keepers almost never have them spaced right. Day before yesterday an old bee-keeper brought in four colonies. When he arrived here the bees were escaping from under the cover. I said, "Have you got the frames properly fastened, so they will not shake about?" "Oh, ya; dey all fas'nd tide." Our apiarist took the hives and put them in position. Next day I asked him whether the frames had been properly stuck up. He smiled a little, and said the combs were spaced sometimes an inch apart, and sometimes an inch and a half, and from that down to a quarter of an inch. The spaces between the combs were almost solidly bridged with brace-combs. Yes, "dey vas all fas'nd tide," and our friend from Holland was right. Now, if this bee-keeper had some sort of a spacing-device to his frames, he probably would have put the combs the right distance apart. I have found, in buying up bees, that farmers and small bee-keepers scarcely ever have their frames properly spaced, and, as a consequence, they never move the frames, and

for a very good reason. Such combs are fixed in a way that practical bee-keepers do not want them. Another consideration, *exact* spacing helps materially to diminish burr-combs, and, as you say, spacers will probably save considerable time.—In regard to those furniture nails, friend M., we have so many irons in the fire now that we will not dare to advertise them. As they are something that can be obtained at almost any furniture store, any one who desires to try them can obtain them readily. If there should be a demand for them, of course we will furnish them.

ERNEST.

FLORIDA.

AN INTERESTING LETTER FROM AN A B C SCHOLAR; GARDENS AND BEES.

Editor Gleanings:—Tourists, visitors, invalids, and winter residents, have about all shaken the dust of Florida from their feet; and those of us who don't want to, or can't get away, are left to enjoy this most beautiful of all Florida seasons—the summer. Those who have seen the State in winter only, can have little idea of the fresh and becoming dress Nature puts on when the rainy season comes; and instead of dormant trees, dried and yellow grasses, and bare, white sand, we have every grass root, and weed and shrub and tree in full leaf and flower. We are told that the past winter and spring has been "exceptional," from a weather point of view; but as that is what we immigrants invariably hear regarding every unpleasant occurrence in weather or business, we have almost come to consider the exception the rule, and pronounce Florida climate rather uncertain.

We have greater changes of temperature, and more of them, than is generally supposed. For instance, on the 14th and 15th of last March the mercury dropped from 90 to 24° in the course of 36 hours. This was "exceptional;" but it is not at all uncommon for the tail of one of your northwestern blizzards to switch across our peninsula, driving the mercury very near the frost-point. Then the wet and dry seasons do not always come as per schedule. In 1889 the rainfall, accurately measured in Orlando by Dr. Thos. Baker, was a trifle over 5 ft. This year the total, up to May 1, is less than 4 inches.

Orange-groves should bloom in February instead of April, as this year. This tardiness proved fortunate, as, on account of the dormant condition of the trees, the frost of March 15 did little damage to bearing groves, except where they had been forced ahead by the use of fertilizers and irrigation. I am not an orange-grower, but I have a few set trees about my home, which came to grief in this way. When the frost came they were a perfect mass of bloom and tender foliage, and by noon of the next day they were the sickest-looking trees imaginable. But our best-remembered lessons are taught by experience; and now I think it will be some years, at least, before we try to turn another dry winter of discontent into a glorious summer by using phosphate and artificial rain. The vegetable-gardeners lost heavily, as that night made almost a clean sweep of tomatoes, potatoes, beans, peas, egg-plant, squashes, corn, etc., and the season was too far advanced to plant again with much chance for a crop.

For although this is called the land of perpetual summer, one can not plant just at any time.

We have our winter gardens and fall gardens; but the unsophisticated Yankee who plants the common garden vegetables between March and September will have have an opportunity to parallel the bee-men's biggest story of "spring dwindling." There are showers and sunshine in abundance, conditions under which one would think the gardens ought to boom; but they don't.

In our market, the quart measure is the standard, and the nickel the smallest coin that will buy any thing. As to prices, would not some of your Ohio gardeners delight in selling their tomatoes at 20 cts. a quart? That has been the price here for the last two months, and they are small tomatoes, and few in a quart too. Very poor celery is 25 cts. a stalk; lettuce, 5 cts. a head; potatoes, 50 cts. a peck; onions, 10 cts. a quart; string beans, 5 cts. a quart; strawberries are cheap now, at 25 cts. a box. Sweet potatoes are one of the very few vegetables that flourish in summer, and are always cheap—from 40 to 75 cts. per bushel. We do not plant slips, as you do, but lay a foot or eighteen inches of the vine across the ridge, and push it into the earth with a forked stick, and in a few days it sends out new roots and leaves.

The swarm of bees, my first and dearest, in more than one sense, about which I wrote you last fall, picked up a little after the robbers ceased paying their unwelcome attentions, but it was not more than a good-sized nucleus when orange-blossoms came in April. But they proved themselves "hustlers" then, and speedily filled their hive with brood and honey. As I wanted experience in manipulating them, more than honey, I divided them a short time ago, and now have a virgin queen five days old, on the three combs I took from the old hive.

Now I must tell you how I got a swarm out of a barrel, and stop. They were runaways, which a negro had caught a mile or so from town, and shaken into a barrel which had no head in either end. For a cover he set a heavy box over them. I bought them, and early one foggy morning my ten-year-old boy Don and I went to bring them home. I had a light box, fixed so as to hold four or five frames, and proposed to transfer their combs if they were large enough; if not, to transfer the bees alone. My first move was to lift that box off the barrel; and if ever I had a "bee in my bonnet" it was a second or two after. They said, "What are you at here? Get out of this!" in good English. So I set the box back and took a little time to consider their proposition. I had found a case to which "Directions for Transferring," as per A B C book, comprehensive as they are, would not apply, and I had to make some of my own. First, we fired up the cold-blast smoker, and smoked them till they couldn't wink. Then I turned the box upside down again, and set it to one side. A few combs were fastened to it, and seemed very soft—so much so that they all fell over to one side as I turned the box. Then I put my little hive where the barrel stood, and jarred the bees into and around it, mostly around it, as it was small and the barrel big. The combs were all too short to reach across the frames; but I put three of them in, upside down, so that the heaviest part would rest on the bottom-bar, and hung them in my box. On a comb not larger than my hand I found the queen, and put her safely into the hive. Now, how to get the bees

in was the question. I could not wait for them to go in of their own accord, as I wanted to take them away at once. There was a narrow alighting-board on my box, so I nailed down the lid, and, making a little paddle, I began shoving them toward the entrance. When I got a bunch of them on the alighting-board I would gently crowd them up to the entrance, and, by making haste slowly, I soon had all but a few stragglers safely housed. Then I nailed the entrance shut, put the box under my arm, and walked home with my prize. How much we enjoyed the early morning walk, the dewy pine woods, and our success, you "bee brethren" will realize if you recall your early experiences when the glamour of novelty was with you.

Just one question: Do any bee-keepers use the crosswise Simplicity frame? I have made my own hives and frames, and, either by mistake or for some now forgotten reason, made the first frames crosswise, and all since. I handled some long Simplicity frames for a neighbor, and do not like them at all, compared with my own. E. J. BAIRD.

Orlando, Fla., May 20, 1890.

Friend B., the crosswise Simplicity frames have been in use for many years, and there has been once or twice a boom on them; but I suppose that most bee-keepers, like ourselves, became disgusted with having two kinds of frames in the apiary; and as the greater part of the frames in use are the regular Langstroth, the crosswise were sooner or later ruled out. I do not know of anybody now that uses them to any extent. The only objection is, they are out of the beaten track.

THE GREAT FLOOD OF THE MISSISSIPPI.

THE OVERFLOW AMONG THE HOMES OF BEE-KEEPERS; THE PROSPECTS FOR A CROP OF HONEY.

Bro. Root:—The greatest overflow of the Mississippi Valley has passed, and all the planters are busy with their preparations for the coming season. Planting cotton is almost completed, and much of it is up, and ready for the hoe and plow. The prospect for the future is very encouraging, and I have no doubt that a large cotton crop will be made. When the year closes, one would scarcely realize that such a flood could have passed over this rich alluvial country, and its ravages so soon obliterated. The corn crop will be small, as it requires to be planted early, so as to avoid the summer drought. A large quantity of millet and peas will be planted for fodder.

The overflow was $2\frac{1}{2}$ feet higher over the country than I have ever known it, having resided here from my birth. The loss of stock was immense, especially cattle. Most of the work stock was saved. Thousands of cattle were driven on to the few high ridges of land above the flood, and a large portion perished of starvation. The destruction of human life was more than one would suppose. More than twenty persons were drowned within a radius of twenty miles of this city. My friend, W. G. McLendon, whom you may know as a large bee-keeper of Chicot County, Ark., lost his son, three years old, who fell from the piazza into the water, four feet deep, while his mother and father were away some distance from the house feeding the cattle that were located on a scaffold. No one saw him at the

time, and his body was not recovered for three days. We can well imagine their grief. He saved his bees, 180 colonies, by elevating them on a scaffold. The levees will hereafter be immensely strengthened, and I hope never to see such an inundation again.

My bees escaped the overflow, as the southern half of the city, with a large district adjoining it, was protected by a ridge of land above the water, where my bees were situated.

The honey-flow now is good. I will commence extracting to-morrow. All the white clover was drowned except that on the high ridges, and that was consumed by the starving cattle. The swamp woodbine, rattan, and wild grapes, persimmon, and many other forest trees, are in bloom. I hope yet to have a good yield of honey. I gave my bees a thorough overhauling, and they are in excellent condition. I have very little trouble with robbers. I use small square pieces of mosquito netting, with cords attached to each corner; and when there is the least evidence of robbing I tie them over the front of the hive. It gives plenty of ventilation to the bees in the hive, and they soon recover from their demoralization; and when the netting is removed they are ready to make a good defense of their home. I rarely keep the net on more than half an hour, unless the robbers have entered the hives in great numbers. I have large nets to envelop the entire hive, when the bees can gain entrance at the top or sides. The netting is my only resort; and as an ounce of prevention is worth a pound of cure, you can not use it too soon.

I devote my apiaries to extracted honey, reserving a couple of hives for comb honey for my own family use, as there is no profit in comb honey in this country.

I leave for Mount Eagle, Tenn., about the 10th of June, where I will devote a few weeks to my apiary there.

O. M. BLANTON.

Greenville, Miss., May 26.

Friend B., when we are tempted to complain of too much rain again, we will remember your sad troubles along the banks of the Mississippi. What a sad, sad story you tell us—a little one only three years old, drowning, because he fell from the piazza of his home! May God be with the poor father and mother.

RAMBLE NO. 25.

RAMBLER IS INVITED TO A DIME SOCIAL.

FROM Fort Plain we rolled gracefully along westward on the Central R. R. We had made up our mind to stop at Oriskany and see Mr. W. E. Clark, ex-president of the N. Y. B. K. A.; but we learned that a sea of three miles of mud lay between the station and residence, and all we could do was to look away across the sea and imagine that Bro. Clark was hard at work tacking leather to those best bellows-smokers of his. We reached Rome about noon; didn't see much evidence of apiculture here, but the people seemed to be very friendly. It was about dinner time, and two fine gentlemen said to me, "Let's go in here and have a dime social."

We accepted the invitation with alacrity, for at home our church had a real good dime social. We escorted the widow Dibble, and ate pumpkin

pie, peanuts, and popcorn to edification, and raised almost \$4.00 for eteeteras for the minister's wife, and also for a pair of magnetic insoles for her shoes.

A DIME SOCIAL.

She, like other females, is troubled with cold feet. It is said, on this account the magnetic-insole trade is heavy among the fair sex. Well, my alacrity came very near ruining me. I am a total abstainer, teetotaler, and "prohib;" and when these fine gentlemen whisked me up to a bar, where vile compounds are sold, and asked me what I would take for a dime social, I was sorely tempted to say brandy with sugar; but I smote the tempter, and won the victory. Said I, "I'll take pumpkin pie;" and these fine men and the dispenser of drinks just laughed the Rambler to scorn. Said I, "My friends, which is better to take, a piece of pumpkin pie, and go hence with a clear head and untangled feet, or that vile stuff that will roll you in the gutter, or heap abuse upon your family?"

Their hilarity visibly subsided, and I withdrew in good order, and I hope my little lecture and stand for principle had a good effect.

Not far from Rome we had a fine visit with an old-time bee-keeper, who has the cognomen of James Moore, aged 83. In war times he had 125 colonies; but they had all died out; clover had killed out, and the bees could get nothing but weed honey, and they could not winter upon it. There's no earthly use to try to keep bees without a good stand of clover.

Said I, "Bee-keepers now feed sugar or taffy, if they find poor honey in a hive."

"Why," said he, "I fed taffy in a bake-tin; also fed maple sugar, nigh on to forty years ago, but weed honey is very deceptive. You can not see much difference between that and clover honey, and can not tell the effect it will have upon the bees; but the taffy was sure cure every time."

"Bee-keepers are now talking a great deal about automatic hiving arrangements. Did you ever have experience in that line?"

"Why, bless you, yes. I had the cutest hive for that purpose you can imagine, nigh on to forty years ago. This hive was invented and patented by Sylvester Davis, of Claremont, N. H. It was called the Platform hive, but I called it the Side Issue. You see, we had hot times them days in politics, and every thing was a crisis, or an issue, so I put the hive in line with the times. Here is an old picture of the hive. You observe that four hives were placed side by side. In the spring, if four swarms were wintered, remove every other one and place

on a new platform, and place empty hives next to all full ones. Close the entrance to the hive containing the swarm, and open the passages into the empty hive. If this is done in early spring, the bees will work through the empty hive; and, finding so much room, they will forget to swarm."

"But, how about a queen in the new hive? In my experience a queen is necessary, to hold the bees to business and make a permanent working colony."

"Yes, yes; but you mean a king-bee. Young men try to get smart nowadays, and fool us old heads with their new-fangled ideas; but do you think I managed bees for nothing nigh on to forty years ago? I guess I know. The process was just as simple when the hive was full, as you could see by the glass in the rear of the hive. Open the front entrance to the old hive, and close the passages between, and the thing was done. The kings

NON-SWARMER BEE-HIVE.

that were always around would set up rule. But this hive was a terror to moth-worms. I used to kill dozens every morning in the little moth-drawers. I had to tend right to my knitting and drop no stitches, to keep them from hatching, when I kept bees nigh on to forty years ago. Then, you see, under the wire-cloth platform was a spring exerciser and feeding-chamber. When it is too cold for bees to fly in the early spring, let the sun shine in here, and what a jolly time the bees could have!"

The inventor also advocated spring feeding, and also gave the following recipe for feeding to make the best of box honey:

Take 25 lbs. best West-India honey; 25 lbs. white sugar; 40 lbs. water; one gill of salt; $\frac{1}{2}$ oz. essence of anise; $1\frac{1}{2}$ pints mucilage of slippery elm; $\frac{1}{4}$ gill of porter (or ale); flavor to suit the fancy.

But I could never see much profit in the plan, and never tried it; and so my aged friend who kept bees "nigh on to forty years ago" had experimented very near to the late methods of taffy feeding and the self-hiving of swarms. There is one thing, however, we think that is for ever buried, and that is moth-traps. Our aged friend found the worms always plentiful, and the trap was a splendid breeder if only neglected, which it was sure to be by nine out of ten of farmer bee-keepers.

We found bee culture not much indulged in, in the immediate vicinity of Mr. Moore. We suppose the weed honey and moth-traps had given it a setback from which it could not recover. As we left our aged friend, the thought that "there is nothing new under the sun" was uppermost in the mind of the

RAMBLER.

Friend R., we are very glad indeed that you stuck to your principles; but I never before heard of using pumpkin pie as a "beverage." Come to think of it, however,

Josh Billings calls it "the delightful bevverij of Nu Ingeland." It is a safe thing to take, however, and I believe that all are agreed in regard to the matter. I well remember Sylvester Davis' patent bee-hive and the Side Issues. The drawers were to pull out and catch the moth, and were a big thing when first introduced. It had its day, however, and passed away, as has been the fate with patent hives for fifty years or more.

MANUM ANSWERS CORRESPONDENTS.

PRACTICAL QUESTIONS ANSWERED.

Friend Root:—In consequence of my talks in GLEANINGS I have received many letters of inquiry on various matters pertaining to the bee-business; and thinking that my answers to some of them may be of interest to some of our bee-keeping friends, I venture to forward you the following:

The first is my answer to a young man living in a neighboring State, who wants a situation as an assistant in the apiary, and who wishes to know how I manage with my men, and how much I pay, etc. My answer was substantially as follows:

Mr. A.—I reply to your favor by saying that I require six men to assist me with my bees during June and July—one apiary being let on shares. I usually hire one or two men for four or five months, and the other four for only two months. The price which I pay varies according to the experience and worth of the man. I have one man who has worked for me seven seasons of six months each. I pay him \$25 per month for May, September, and October, and \$30 per month for June, July, and August. The time is divided in this way, so that if, from any cause, he does not complete his full time, there would be no question as to the price to be paid for what time he works. I have another man who has worked for me a number of seasons, and who prefers to work only through June and July. I pay him \$75 for the two months. I have another man who has worked for me one season; and as he is an excellent and faithful man, I pay him for this season \$25 per month for three months. For a new hand, or one who has never worked for me, or for any one near me who practices my methods, but who has had a little experience with bees, and who understands the theory pretty well, I pay \$40 for two months, or \$70 for six months, when they insist on working through the season for the sake of learning the business. Of course, their board is included at above prices. I locate one man at each out-apiary where he is to remain during the swarming season, which is usually from five to seven, and sometimes nine weeks, but more often six weeks. I expect my men to be at their post every day during this time, Sundays and all; and while I do not expect a man to do any unnecessary work on Sunday, I insist on his being on hand to hive swarms that may issue. It is my practice to visit each apiary once or twice each week, to give instructions, and to assist the men when assistance is required. You say that you have had a little experience at home with a few swarms, and that you have read several bee-books, such as Cook's Manual and the A B C, and that you have taken GLEANINGS two years, and that you would like to work the first

four months of the season, and that you are a young man of good habits, and anxious to learn the business. You ask if I expect my men to do other work not pertaining to the bee-business. Yes, I do those who work before and after the swarming-season. I have a small farm—40 acres—and when not busy with the bees I sometimes ask my men to assist in planting, and in the fall in harvesting; but my farm being small, and there being so many of us, the farm work is light, and quickly done. Now, in view of these considerations, and what you say about yourself, I will pay you \$60 for May, June, July, and August.

HIVING TWO OR MORE SWARMS TOGETHER.

Mr. Manum:—When you hive two or more swarms in one hive, how do you unite them without their quarreling? and what do you do with the extra queens? My answer is, that, in a large apiary, there will usually be several swarms out in one day—we sometimes have 20. In that case two or more may be hived together without fear of their quarreling; but if they issue one per day, or one has been hived two or three days, and it is desired to unite another with them, I first cage the queen already in the hive, and hang the cage in the hive, and then shake the bees off the combs in front of the hive, and at once dump the new swarm with them, having first secured their queen, and at once sprinkle them, hive and all, with sweetened water well flavored with peppermint, and allow them to run into the hive. Just at night I liberate the queen. Now, if the extra queen is an old or inferior one, I pinch off her head; but if she is only one year old, and a good one, I either introduce her in place of some old or poor queen, or return her to the hive from which she issued, after first removing all queen-cells. Having lost so many bees by swarming, she will not be likely to attempt to swarm again the same season. At this time I usually discard all my two-year-old queens, and for the past two years I have had calls for all such at 50 cents each. By this practice I winter no queen over one year old. If you wish much increase you can hive the extra queen with just enough bees to cover one card of hatching brood; and by giving them a card of brood occasionally, you will soon have a colony in good condition for winter, without having much reduced the working force in those hives run for surplus.

WILL IT PAY TO CONTRACT?

Another makes the following inquiry:

Having read much of your writing in *GLEANINGS*, with interest, I venture to ask whether you think it pays to contract the brood-chamber during the honey-flow, to secure all the honey in the surplus receptacles.

My answer to this question is this: In a locality where no fall (or dark) honey is stored in sufficient quantities to winter the bees, it will not pay, at the present low price of honey and high price of sugar. When honey sold at 20 to 25 cents per lb., I practiced contracting with profit. But I prefer now to allow them the full number of combs, so that the bees may store enough, or nearly enough, honey for winter, while the white-honey flow lasts, as we very seldom get any honey here after the basswood season. But if in your locality you are quite sure of securing fall honey enough for winter stores I would advise contracting during the white-honey flow. You should be governed in this by your

locality, both as regards quantity and quality of honey, as well as by the price your honey sells for.

PACKING FOR CHAFF HIVES.

Another man asks:

What is, in your opinion, the best material for packing the so-called chaff hives? I have made a few Bristol hives from your description of them in *GLEANINGS*, and the only material for packing I can get near by is unseasoned basswood sawdust. Do you think this would soon dry after packing, so it would answer the purpose?

Answer:

No: I would hardly dare use it, for basswood will mildew very quickly in hot weather; and, again, sawdust alone will pack too hard to answer a good purpose; because the harder any such material is packed, the more it becomes a conductor for both heat and cold. I believe fine *dry* planer shavings, such as are made by planing well-seasoned lumber, are as good as any thing which can be got cheaply. Now, if the bottom of the hive around the outside walls is air-tight, these shavings will form a multitude of little dead-air spaces; while if, on the other hand, the bottom of the hive is not tight, so but that it will admit of air, these same shavings will form a multitude of little air-channels up through which fresh air will continually circulate, which would doubtless be a benefit to the bees in hot weather, if not in cold. So, then, my preference is dry planer shavings. Oat chaff, or very fine cut straw, are good.

A CALL FROM A NEIGHBOR.

"Halloo, Charles! walk in. I am glad to see you this lonely rainy day."

"Well, I have called to have a little chat with you about the bees. Jennie said you were in your office, so I walked right in. I hope I am not interfering with your writing."

"Oh, no! not at all. I was just having a little mechanical chat with our friend Root. Well, have you been out to your apiary recently?"

"Yes: I was there yesterday, and I found things a little mixed. You remember I told you in April that I had lost only 4 per cent in wintering. Well, that was true; but since then every one of my light colonies has gone up; and some that were not so very light are missing. The boy I have there says that a number of them have swarmed out, and left some brood and lots of honey, and I have called to ask you to tell me the cause of such conduct."

"Well, Charles, you know we have had a very cold backward spring, which has been a trying time for the bees, especially light colonies. They all being so short of pollen, they have worked hard to get a little whenever they could fly out, and many times they ventured out when they ought not to; consequently the old bees have wasted away to an alarming extent. In fact, there are scarcely any old bees left in any of my hives; therefore those that came through light did not have the strength to rally and survive the wasting-away of their small numbers, and had to succumb to their fate—dwindling."

"But, what was the cause of fairly good colonies in the spring swarming out and leaving their brood and plenty of honey?"

"Well, now, let me ask you a question. Did those that have swarmed out have young or old queens?"

"Nearly all of them had old queens. Two of them had young queens hatched last August, but

they were not very good layers last fall, so I do not care much for them."

"Well, then, one cause of absconding is due to the queens, and can be traced out thus: The queens being on the decline—or poor—and the colonies being light in bees in the spring, the queens did not get to laying early enough to get a batch of young bees hatched out before the crisis came; and finding that they were weakening instead of gaining, and not being able to cover and care for their brood, they became discouraged, and swarmed out; when if they could have held out a few days longer until the brood commenced to hatch, they would not have swarmed out, because a few young baby-bees would have held them. I have given such colonies a few young bees from other hives, with good success, when discovered in this condition. If the weather had been favorable, all of these light stocks would have pulled through all right; but we have had about the hardest spring I ever knew, and we shall have no light colonies this summer to bother with, as they are all gone where the woodbine twined."

"Have you engaged all your help yet for this season?"

"No: I am two men short."

"What are you going to do in that case?"

"Well, I have got to run three apiaries myself—two out-apiaries, besides this one at home: so when you are enjoying yourself in your one apiary you can think of me with three to manage, besides the other boys to look after."

"But, how are you going to do so much yourself, pray tell?"

"Well, I am going to try to prevent swarming in the two out-apiaries, and the home apiary I shall run principally for extracting; and I hope, by giving them room enough, they will swarm but very little if at all; and one of the out-apiaries I shall manage by removing the queens just before they prepare to swarm, according to Elwood's method, and in the other out-apiary I shall try to prevent swarming, according to Manum's method, which I do not care to tell you about yet, as I am not sure it will prove practical on a large scale. I have tried it with only a few colonies."

"Well, I hope you will be successful; but I think you will have your hands full before the season is over."

"Thanks. I assure you I shall work faithfully for success, and succeed I must, in some way."

Bristol, Vt., May, 1890.

A. E. MANUM.

THE TEXAS AGRICULTURAL ANT.

PROF. COOK TELLS US SOME WONDERFUL THINGS ABOUT ANTS AS WELL AS BEES.

I HAVE received from Mr. W. D. Allen, of Koose, Texas, a fertile (or wingless) queen of these strange ants (*Pogonomyrmex barbatus*). He requests a report through GLEANINGS, and desires especially to know whether there is more than one queen in a colony, and whether there is any way to exterminate these rivals in agriculture. As they allow no vegetation within a radius of six or eight feet of the door to their nests, the damage they do is by no means insignificant. I am specially glad to receive this queen ant, as we have none of this species in our collection. I shall be very grateful if Mr. Allen can send me more queens—both winged

and wingless—males, and workers—both large and small.

I am also glad to present to the readers of GLEANINGS something of the life and habits of these interesting insects, especially as they are of peculiar interest to bee-keepers, as there is much in common in the life economy of ants and bees; and the student of either will the better understand his subject if he study the other. These ants (see cut) are reddish brown in color. The queens are a little more than half an inch long. The males—drones—are half an inch long, and the workers, of which there are two sizes, are respectively one and two-eighths of an inch shorter than the males. The young queens—virgins—and males have wings, while the workers and laying queens are wingless. Like bumble-bees they live in underground

nests; though these ants tunnel into the earth for several feet, and have quite extensive galleries. They may have a hill or mound above their tunnels, or they may have no hill. The entrance to the tunnels is usually by one opening; but there may be two, three, or four, all near together. They take their name, "agricultural ant," from the fact that they keep a circle, with a diameter of from six to sixteen feet, about the entrance to their nest, entirely free from all kinds of plants; and radiating paths, also, cleaned of vegetation, stretch for many feet in every direction from the central circle. These paths are five or six inches wide at their inner end, and become more narrow as they extend. They are also husbandmen, in that they garner into their nests seeds during summer, on which they feed at all seasons. Their paths are highways over which they bear the heavy seeds. To show how brainy they are, it is reported that if, from heavy rains, their granaries are flooded, the seeds are carried out to dry; and, when dry, are carried back. To show their patriotism, it is reported that, in case of storms, they will plug the entrance with their bodies, and thus die for their kindred and home. There is a certain kind of grass—"ant rice," which is nearly always found about the cleared circles of these insect agriculturists. It is believed that the ants sow the seeds purposely to raise their favorite forage crop; while some argue that the presence of the ant rice is accidental, coming from seed carelessly left by the ants. There is some reason to believe that there is purpose in the seed-sowing. So we see these Texan ants are veritable agriculturists, and no mean rivals of man. The young queens—virgins—have wings. When the season for mating comes—in June—the males and females fly forth and mate. It is reported that they mate on the ground (?). The males die at once, and the now impregnated queen flies off, and alone commences to dig a home. So, like the queen bumble-bee, the queen-ant, at first, has to do all the labor. The queen ant, finding her wings in the way, bites them off. The hard command, "If thy hand offend thee," is obeyed by these insects. Who shall say that insects are destitute either of intellect or morals?

All the ants which are produced at first are workers, and those produced while the queen is not only chief, but the only "cook and bottle-washer," are the small workers. Thus, as with bees, a stunted

diet results in undeveloped females, or workers, and a very stunted larva produces small workers.

As the season advances — June — the males and queens again appear, and fly forth to mate, after which the queens commence new colonies.

To answer Mr. Allen's question, I think there is only one queen in the colonies of these ants, though I may be wrong, as many species of ants have several queens in a single colony.

Ants are very muscular. It has been estimated that a man, to equal an ant in performance, would have to walk over 150 miles a day with more than a ton weight on his head. Like bees, ants are very neat, and spend much time in scrubbing and combing. Unlike bees, the ants scratch and comb each other, and there is every indication that the recipient of such favors receives them with great satisfaction. The ants are also seen to sleep so soundly that they are waked with difficulty. From this we may very safely conclude that bees also take naps. As the agricultural ants are always *all* in their nests from noon to one o'clock, it would seem probable that this is the usual napping time.

Any who are specially interested in these ants will do well to read the very interesting book by Rev. Mr. McCook, of Philadelphia, on this insect. This is a book that should be in every public library.

Mr. Allen asks for a remedy, or means to exterminate these pests. I have no doubt but that bisulphide of carbon, poured into the tunnels between twelve and one, will quickly destroy these ants. It is used successfully to destroy the prairie-squirrels in the West, and I have used it here with entire success in killing the ants that are often so annoying on our lawns. I have just explained the use of this substance, and the other insecticides which I have found useful in killing insects, in a bulletin entitled *Insecticides*, which any one can get free by addressing a card, requesting it, to Secretary H. G. Reynolds, Agricultural College, Michigan.

Mr. McCook explains a trap which he says will very soon exterminate all the agricultural ants of any nest. This consists of a tin box set over the hole, so made that any ant passing either in or out must pass over an inclined piece of bright smooth tin, whose roof-like edge stands or projects over the box. Thus the ants are precipitated into the box; and as they can not get out, they are easily killed. I should suppose that, if the box were quite large, and contained kerosene, it would need no attention after placing it, else it would need emptying each day.

A. J. COOK.

Agricultural College, Mich., Apr. 26.

I am sure, dear friend, we are all very much interested in what you have just told us. I have heard of those ants sowing rice and tending to the crop. Now, although my faith is very great along this line, I must confess that I am strongly inclined to think, with the others you mention, that this must be a mistake. Even though the ants are seen depositing seeds, I do not believe they do it with any expectation of waiting for a crop. Some one has said that the lowest types of mankind can be distinguished from the highest types of animal instinct, by a very simple matter; namely, no animal ever yet had sense enough to build a fire to warm him when cold. In the same way, I should say that

no animal or insect ever had or ever could have sense enough to sow seeds and wait the production of a crop. — Are you not putting it a little exact to say that the ants are all in their nests from noon till one o'clock? Did you not mean to say for a period of about an hour, usually, during the hottest part of the day? Without clocks and watches they would have to go out and take a look at the sun to see when it was about napping time. I do know that domestic animals get into the habit of judging time very accurately. Our Clydesdale team has learned to make a fuss if they can not get into the stable and be fed when the whistle blows. A few days ago our teamster told them to go on; that they could not stop that particular night, even if the whistle did blow, and one of them gave a loud whinny of disapproval.

THE HEAVY LOSSES OF BEES IN YORK STATE.

ITALIANS WINTERED BEST; BLACKS AND CARNIOLANS ALL DIED; HONEY-DEW THE CAUSE.

I SEE the report of James Markle, in last issue, from New Salem, N. Y., that he lost most of his bees. I live about 12 miles from him. The loss of bees through this part of the State is fearful. It has cleaned out whole apiaries, and covers a large territory. The whole cause is bad stores, or, in other words, the large amount of honey-dew that the bees gathered last September. I put into the cellar about 125 colonies. All perished except 60 colonies of Italians, the rest being blacks. The Italians had their hives stored with plenty of good early white honey, and had no occasion for storing honey-dew, as their hives were full of good honey. When the honey-dew came, every colony of pure blacks perished. Does this not prove the superiority of the Italians over the blacks? Last season the blacks did nothing, and hardly pulled through the summer, while the Italians in the same yard gathered enough to live on, and stored their hives full, and gave some surplus. The blacks have no honey stored; and when the honey-dew made its appearance they had room for all they could gather, and in a few days their hives were full. As it became salvy as soon as gathered, it was impossible to extract. I see you doubt, in your foot-notes to Mr. Markle's report, that the food was the whole source of the loss. It certainly was, and nothing else. If it was not, why did those having honey-dew *all* perish, and those having good pure stores *all* live, being all wintered in the same cellar. If the bees had all been left out of doors, the loss would not have been 5 per cent, as those that were left out had a cleansing flight every few days all winter.

I am done now with black bees. They are certainly not worth bothering with in this section of the country. I have kept about an equal number of blacks and Italians for the last 15 years, but now I will not bother with the blacks any longer. All they are good for is to work on buckwheat when we have a good August, and honey-dew when it comes. Although my loss has been heavy for me, never losing any in winter before, I am not discouraged. I have 60 good strong colonies of Italians left. I shall try all the harder to get back to

my number again; but it is hard for a poor man to lose so many.

CARNIOLANS BAD FOR WINTERING.

I had a few colonies of pure Carniolans. They were the first to perish. I have tried them now four years. They are no better than the common black bees, but worse to swarm.

Gallupville, N. Y., May 20. F. BOOMHOWER.

AN A B C SCHOLAR'S EXPERIENCE IN CALIFORNIA.

STARTING WITH A FEW FOUL-BROODY COLONIES, AND INCREASING TO 80 HEALTHY ONES.

The rainfall in Southern California has been very large, being over 40 inches, while in ordinary years about 20 is a fair average. Such rainfalls have preceded good honey years in the past, and a good flow of honey was predicted by the bee-men for this season. This prophecy seems likely at present to be fulfilled. Swarming has been going on at a lively rate, and honey is now coming in freely. We have this year's swarms from which we have already extracted and taken comb honey. Some of them are also ready to swarm again.

This is all very encouraging to us. We know nothing at all of bee culture except what we had read in the A B C book and a few copies of GLEANINGS. We took an apiary here that had dwindled from 150 down to 18 hives, containing bees. Foul brood had been among them, and we knew what we had to contend with. Of the 18, about 6 or 7 were unaffected, and the others have at this date mostly gone with the majority.

We also purchased another apiary of 22 hives, also affected. The price paid was so little that I am ashamed to mention it without your knowing all the circumstances. I noticed they were about as willing to give us *all* the apiary as a part of them for the sum we offered. We had very little money, and were obliged to think before investing. We commenced by buying empty hives at a low price, taking out comb and boiling them in an iron tub. The wax, we traded to a supply-dealer near by, for foundation. We then removed all diseased brood and gave foundation in place, removing the bees at the same time to a cleaned hive. We now have a rousing apiary of about 80 hives. I never knew that bees could work as ours do now from daylight to dark. About 10 or 12 swarms we took from trees and buildings, or picked up in other localities during the swarming season. The others are the increase of our apiary. We have rented a furnished cottage, and it would seem that we shall be able to live comfortably. I might say, that California was as new to me as the bee-business. It was a strange land, strange people, and a strange business at the same time. Such sights as raising an empty hive and finding a lizard a foot long inside would be new to many of your bee-family. Every step of the way was new and novel. We often read the A B C book until late at night, that we might know how to act the next day. My helper is a young man of more than ordinary practical talent and discernment of things. Though scarcely able to speak or read English, much of the credit of success is due him. I read the book and gave him the outlines, and was often astonished at the almost marvelous comprehension, and even enlargement of the subject, which he showed.

To the bountiful year, given by the kind heavenly Father, of course, is due such an increase. Henry keeps a Bible in the bee-house, and at times reads to me while I pronounce and explain the hard words. He thinks it better than gold, and digs deeper and deeper into its mines of truth day by day, so that, besides becoming bee-keepers, we are fitting for the pure and beautiful country beyond. Oh that we might get right, before the summons comes to pass over!

To speak of bees again, I will tell you what I did. I transferred a hive, cutting out several combs, and fastening in other frames, without veil or smoker, and without getting stung. I do not know whether it is a feat or not. It was a good swarm I found in an odd-sized hive piled up with others some distance from our apiary. I did not want to go back again, and to save time I put it in a regular-sized hive, as above stated. I raised the cover *very* gently, and got them exposed to the sun and air, and then I think they did not know their own hive, and so did not defend it. At any rate I cut out the combs and fastened them into the other frames with sticks; and though the air was full, not one ventured to sting.

It is necessary to shade all hives here. We buy store-boxes for shades, and also use burlap some, under the cover, and hanging down in front to shade. We have just finished painting the hives white, the better to stand the heat. I have seen combs at the front of the hive (a black one) that were melted into a mass.

We get 12½ cts. at the village store, for comb honey, in 1-lb. sections. It is retailed at 15. For extracted we get 6 cts. by the 60-lb. can, and 7 for small quantities. We have just prepared 32 60-lb. cans for honey, and hope that will not nearly hold it. We have extracted at this date about 8 cans, and the white sage is just beginning to furnish honey. "Black sage" has been the best honey-plant up to this date. Swarming commenced March 28, and was wonderfully lively for a time, but now seems mostly over. W. S. RITCHIE.

Sierra Madre, Cal., May 19.

BRACE-COMBS, ETC.

FRIEND DOOLITTLE ARGUES THAT WE DO NOT WANT THEM REMOVED.

It has been with much interest that I have read all the arguments, experience, etc., along the line of wide and thick top-bars for the frames to do away with brace-combs, all, or nearly all, seeming to think that it would be a great advantage to "be rid of such a nuisance," or, at least, they seem to think of these brace-combs only as a nuisance. Now, with me I consider these brace-combs a great help, and for years I have allowed them to remain on the top-bars of my frames, because I considered them of value; that is, I consider them of more value than they are a disadvantage. Were I working an apiary for extracted honey I might change my mind a little, perhaps; but for comb honey I would not allow any one to scrape them off my frames for 50 cents per hive. Years ago I considered them a nuisance, and so each year I scraped them off in the fall when I prepared my bees for winter, till one fall, through an extra amount of other work, I did not get time to go over more than about two-thirds of the apiary in preparing for

winter, guessing at the rest, or, what amounted to the same thing, weighing the hives to come at the amount of stores they had, instead of inspecting every frame, as I usually do. Previous to this I had used the Hill device, or something similar, to give the bees a passageway over the combs during winter, as is so often recommended to be used under the bee-quilt; but frequent examinations during winter satisfied me that these brace-combs, which I had taken so much pains to remove, answered every purpose of the device, besides being much cheaper, as well as requiring no room in my shop, or lugging back and forth from shop to apiary both spring and fall, which they required when used. But their greatest advantage appeared when I came to put on the sections, for the bees seemed to consider them as little ladders on which to climb up into the sections, for it was a very noticeable fact that the bees entered the sections much sooner where these brace-combs were left than they did those where they had been removed, and, if I remember correctly, I so wrote in *GLEANINGS* at the time, advising all to remove the brace-combs from the bottom of the supers, but not from the tops of the frames. The next year I tried the same experiment again, and so on for several years, till at last I became thoroughly convinced that these brace-combs added largely to my crop of comb honey by getting the bees into the sections much sooner than they otherwise would.

Now, some may say that it is no use getting the bees into the sections as soon as the first honey comes in; but I claim that this has very much to do with our crop of comb honey. It is not that the first four or five pounds of honey stored in the sections could be sold for so much cash that I wish it placed in the sections, but all my past experience teaches me that, for every pound of honey stored in the brood-nest at the commencement of the season, there will be ten pounds less stored in the sections that year. Let the bees once commence to store honey in the brood-chamber thus early in the season, and they are loth to enter the sections at all; and, instead of giving us lots of section honey, they keep crowding the queen from the cells more and more till, when fall comes, we have little honey for market, and our bees in poor shape for winter. When we come to fully understand this fact we shall see that, wherein these brace-combs are the means of having our bees enter the sections sooner, just in that proportion are they of value to us. Try the experiment, brethren, and see if, at the end of such a trial, you will not be willing to put up with the inconvenience they cause you, for the sake of their great value.

CAPPING COMBS.

Picking up a paper lately, I read an article arguing in favor of extracting honey before it is ripened, in which were these words: "It stands to reason, that, if a colony is saved the time of capping over hundreds of square inches of comb, it will gather just that much more honey." This I claim is a mistake wrought out by the writer in not being familiar with the laws that govern the inside of the hive. If the bees which capped the cells were the field bees, and if these cells were capped in the day time, then it *would* stand to reason, as our writer claims; but when we come to know that (when a colony is in a normal condition) it is the bees that are under 16 days old which do all of the wax work, and that the larger part of this wax-working is done at

night, then we see that the capping of the combs plays no important part in the production of honey. The bees which cap the honey would not go into the field if there were no honey to cap, so I do not see where there would be any saving in keeping them idle by extracting the honey before they had time to cap it. If it is to be argued that it would save the honey that went into wax to form the cappings of the combs, then I answer, that, according to Prof. Cook and my own observation, bees always secrete wax enough for the purpose of capping combs, during a honey-flow, whether combs are capped or not; hence it is wasted if they have no place to put it. Looking at it in the above light, which is the correct one, in my opinion, there is no saving to the bees in extracting unripe honey. More bulk of honey will be obtained, I admit, but not because time is saved to the bees.

Borodino, N. Y., June 6.

G. M. DOOLITTLE.

Friend D., I remember quite distinctly that, when you paid us that visit ten or twelve years ago, one of the things you were very emphatic about was that you did not want the burr-combs removed from the top of the frames; and during all this discussion in regard to brace-combs the matter has been on my mind, and I have been feeling quite anxious about it; but I had not got started until you took it up. Now, I think very likely you are right. But you use an arrangement amounting virtually to the wide frame for holding sections, put over the tops of the frames. Now, if I understand you, you let these burr-combs go right up and be built right on to the bottom-bars of the wide frames. In that case you have a sticky, dauby mess every time you remove the wide frames to take out the sections. Then you have the inconvenience we all know about so well, when putting them back again. Maybe you have some way to obviate this latter matter, however—I hope you have. I once decided that I would let the crate or super be built fast to the tops of the frames, and let them remain there during the honey season, taking out the sections when I want to, by removing them one at a time from the crate or super, to get rid of this inconvenience of breaking loose from the burr-combs. I emphatically agree with you in regard to getting the bees at work in the sections before very much honey is put into the brood-combs, although I should not say that one pound in the brood-nest very often prevents ten pounds from going into the sections. I am inclined to think there is quite a saving in the quantity of honey by extracting before the combs are capped, although I quite agree with you in your statement that the bees that gather the honey do not, as a rule at least, cap the cells over. Ernest calls my attention to the fact, friend D., that you use a deeper frame than the shallow Langstroth, and there is a pretty general agreement that bees will go into boxes quicker from shallow Langstroth combs than from the square Gallup combs. He says, too, that many who are using thick top-bars declare they do not hinder the bees from going up into the boxes, even though no burr-combs are built over these top-bars. I should be very glad indeed to have our good friend J. B. Hall, of Woodstock, On-

tario, the pioneer of thick top-bars, tell us what he thinks about it. He is an adept in getting large amounts of comb honey, as all know who talked with him at the exhibit at Toronto.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 162.—*a. What do you pay for competent help in the apiary? b. Do you employ boys or men? c. Which is the cheaper help—the average boy from 12 to 16, or a full-grown man, the boy receiving wages proportionate to that of the man?*

I don't hire any help.

Ohio. N. W.

A. B. MASON.

a. We do our own work.

Illinois.

MRS. L. HARRISON.

a. \$30 per month and board. b, c. A good competent man is always cheaper.

Louisiana. E. C.

P. L. VIALLO.

a. From \$15 to \$30 per month, according to reliability and experience of the hand. b. Men. c. Man.

Cuba.

O. O. POPPLETON.

Farm wages. b. Men. c. The man, provided he knows as much as the boy; i. e., enough to do as he is told.

New York. C.

P. H. ELWOOD.

\$1.50 per day. b. Employ a man. c. A handy boy will do full as well as a man, and will work cheaper. The trouble is to get the handy boy.

New York. E.

RAMBLER.

I have never paid regular wages to any except boys of the ages mentioned. I paid them 40c per day. I should prefer to pay more for older and more reliable help.

Illinois. N. C.

J. A. GREEN.

We employ either boys or full-grown men, and pay without regard to the age, according to the good will and ability. A man may be too dear at 50 cents a day, while another can be cheap at three dollars.

Illinois. N. W.

DADANT & SON.

I do not hire. The man who thinks he knows much about bees, and really knows nothing as he ought, is rather unpromising timber to make help of, compared with a good boy who is willing and anxious to learn.

Ohio. N. W.

E. E. HASTY.

a. Don't employ any. c. A boy 16 years old will do as much work as he ever will during 10 hours each day, and should be paid as good a price as a man, providing he does his work as well. There is a difference in boys as well as men. A poor one of either does more damage than good in any apiary.

New York. C.

G. M. DOOLITTLE.

a. About \$35.00 per month for men; 15 to 20 for boys. b. Both. c. A good boy is as good for some kinds of work as a good man. It depends on the kind of work you have to do; some parts of the sea-

son, boy's work is the cheaper. As a rule I should prefer experienced help—men instead of boys.

Ohio. N. W.

H. R. BOARDMAN.

a. Usually \$25 for an inexperienced man to work with me, and \$35 to \$50 for experienced help; amount depending on skill of man, amount of honey coming, and whether he has to take charge of an apiary himself. Also somewhat by the supply and demand of help in the market. b. It seems impractical to work boys in to advantage, except where several hands are needed in an apiary.

California. S. W.

R. WILKIN.

a. \$30 per month with board is the highest that I have paid for the season. I have hired more for the past 15 years at \$1.00 a day and board, than at any other price. This was to a man that has been with us 18 years, and has proved to be the cheapest help that I have hired. b. Both. c. I have had some boys that were excellent helpers; but find quite a relief in having some one with age and experience sufficient to shoulder a part of the care and responsibility.

Wisconsin. S. W.

S. I. FREEBORN.

a. My help has always been in the family. b. Mostly women. c. I think I'd rather have an average man than an average boy, but would rather have an unusually bright and thoroughly trustworthy boy of 16 than an average man, and would prefer a very competent man to either. My principal help is a slender girl that I wouldn't swap for either of the above, although she is such a driver that I sometimes threaten to "strike" for less hours or leave for an easier place.

Illinois. N.

C. C. MILLER.

a. From \$25 to \$30 per month, according to the length of time they work. b. Good men, when I can get them. c. The full-grown man every time, if competent, and I want no other, though I am sometimes obliged to hire young men; and I must say that I have had young men 16 to 20 years old that did well. I always prefer to keep my old help year after year when I can; but it often happens that one or more wish to start business for themselves, so I then have to look for new hands. This happens nearly every year. See page 455.

Vermont. N. W.

A. E. MANUM.

We hire boys from 16 to 20 years; paying about \$10 a month and board, for the first year, for a 16-year-old boy. Some boys are good help at 12 to 14 years, at about \$8.00 per month. We rather have boys than men; they are quicker, and will do more work than the average inexperienced man. We keep our boys as long as we can. They are worth more and more every year. But as our work in the apiary lasts only about a month each year, our boys usually leave us after two to four years, for some other more steady work.

Wisconsin. S. W.

E. FRANCE.

You are aware that I have students who come here to learn the business each year. From the best of these students whom I can get to work for me, I select my foreman, and this one man is all I have to hire. This foreman is usually from 20 to 30 years of age, and all but one unmarried, so far. My son who has acted in that capacity the past year is only 19 years old, but is unexcelled as foreman of my apiary; 12 to 16 is too young to manage an api-

ary, either with or without help. The man would be the cheapest in the end. I pay from \$300 to \$400 a year and board. I have work in the winter; but I value their services at just half in the winter what I do in summer. Another thing I wish to mention here. I have had twenty applications for men who have learned apiculture with me, for every one I can furnish. The demand for practical apiarists who are really worth something, is away ahead of the supply, and that, too, at wages about double what farm hands can get.

Michigan. S. W.

JAMES HEDDON.

Dear friends, I am very glad indeed to get the above answers, and I am glad, too, to know that in the main they pretty nearly agree with my own experience in hiring help. My great business in life has been in employing help; and not only have I done it for personal gain, but I hope and believe that the inspiring motive has been to solve this great problem of "something to do." Now, then, I think you pretty nearly all agree that it is *not* a discussion between men and boys; neither is it a discussion between men and women; but the whole matter hinges on this: The faithful and the unfaithful, or, if you choose, the half-hearted and the whole-hearted. I have sometimes decided that I could not wear myself out any more in running after boys; but in a very little time I would decide again that one good faithful, whole-hearted boy, was worth more than half a dozen men who were intent only on passing the hours and getting their pay. The one who enters heart and soul into his work, and strives to make it a *success*, is the one that is helping. We are just beginning to pick strawberries. As we are getting 18 cents a quart for them, it pays to go over a large extent of ground for only a few berries. As fruit is very scarce in our market, everybody is hungry for it. My first mental question was, "Where is the boy who will get these few berries—who will get them *all*, and not waste his time, nor eat the greater part of them?" I instantly fixed my mind on *one* boy whom I knew would be faithful in every respect. He would not need any watching, and there would not be any doubt in regard to the result of his search. He could not get them all before schooltime, so help was needed. After running over in my mind at least half a dozen, I decided on one of the very smallest. He has all the qualifications of the other one, and I am sure, without saying any thing to him about it, he will not eat a berry without permission, during his two hours' work. A few days ago when I was discussing with the foreman about trusty boys, this boy overheard our remarks, and looked up with a bright, manly face. Said he: "Mr. Root, am I a good boy?"

"Yes, H.," said I at once, "you are a good boy;" and I mentally added, "May the Lord bless your faithful, honest little soul." And my prayer is now, "May God help us to so educate our children that there shall be *more* faithful, honest ones." It needs no spirit of prophecy to say that such ones will rise. Why, no matter how many crowds are going here and there for work, there will *never* be enough of the real honest

and true—the real genuine nobility of the earth, and the *salt* of the earth. May God help us!

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

HONEY STATISTICS.

The following are the rest of the statistical reports, which came too late for insertion in our last issue. Some of the correspondents were away—or, at least, in the far corners of the United States, so that their reports came in a little late.

ARKANSAS.

W. H. Laws, Lavaca. W. C. 6-2.

a. b, 2; outdoor.

CALIFORNIA.

G. W. Cover, Downieville. N. 5-31.

a. 80; outdoors; b. 80; in box and Langstroth hives outdoors.

W. W. Bliss, Duarte. S. E. 5-23.

a. 5; outdoors; b. 15; outdoors. The season so far is far above the average.

Wm. Muth-Rasmussen, Independence. E. 5-20.

a. 2; outdoors; b. don't know; probably the same.

J. P. Israel, Olivenhain, Cal. S. 5-20.

a. 7½; outdoors; b. 10; outdoors. No cellars for bees are used here.

R. Wilkin, San Buenaventura. S. W. 5-25.

a. 6; outdoors; b. 5; outdoors.

GEORGIA.

J. P. H. Brown, Augusta. E. C. 5-22.

a. 10; outdoors; b. 20; outdoors. Bees mostly kept in the old box gum.

INDIANA.

T. H. Kloer, Terre Haute. 5-27.

a. 5; nearly all on account of queenlessness. Wintered outdoors. b. There was little loss during winter, but during the present month many have died of starvation, dwindled away, or swarmed out. Bees are just beginning to make a living.

KANSAS.

Frank H. Howard, Garden City. 5-23.

a. 10; outdoors.

MICHIGAN.

W. J. Carroll, Otsego. S. W. 5-26.

a. 90 in cellar, loss 1; 10 outdoors in chaff, no loss. b. The loss in this neighborhood is very light, not more than 10 per cent. Bees wintered in chaff are in much the best condition.

MINNESOTA.

A. F. Bright, Mazeppa. E. 5-24.

a. 25, cellar; b. 30, cellar. The loss in cellar was comparatively light, greatest loss being after their removal from the cellar, on account of the cold backward spring.

MASSACHUSETTS.

A. A. Sanborn, Westfield, Mass. S. W. 5-22.

a. Loss very light outdoor. b. Loss very light; both methods.

OREGON.

George Ebell, Baker City. E. 5-23.

a. 100 per cent. b. Outdoors in chaff.

TEXAS.

B. F. Carroll, Blooming Grove. 6-2.

a. None; outdoors in S. hives. b. None; outdoors.

VIRGINIA.

J. W. Porter, Charlottesville. C. 5-24.

All outdoor wintering in Virginia. My own bees mostly slaughtered by foul brood. Bees generally wintered well; small loss.

WASHINGTON.

J. H. Goe, Mossy Rock. 5-24.

b. 25; outdoors in common hives. The winter here was very hard on bees.

W. W. Maltby, Port Angeles. 5-23.

a. b. 7, outdoors.

WISCONSIN.

J. C. Sayles, Hartford. S. E. 5-20.

a. 2, cellar; b. 2, cellar and outdoors.

HEAVY LOSS IN A LARGE APIARY, BY THE MISSISSIPPI FLOOD.

I have just had a severe loss among my bees. I live in the Red River Valley. I had 435 colonies on the first of April, and their increase from that time in three apiaries. On the 30th of April several levees broke in my neighborhood, and the water ran over my place. I put them up on pens four feet high. The water rose so fast, and the current was so strong, that I could not do any thing for

them after it got that high. The pens were washed away, or knocked over by drift. I have only about 40 left, and they are damaged, and the brood got wet. I have changed them into new hives. The water was 33 inches deep in my house. Some houses were washed away, and nearly all fences are gone, and crops destroyed. A great deal of stock was drowned, but no loss of human life that I have heard of. Some of the hives have been found in the woods, with a few bees in. The dead brood smells bad. Will it cause foul brood?

Rush Point, La., May 24, 1890. W. J. DAWSON.

No, sir. Foul brood can not start without a seed, any more than corn can grow where none is planted.

IMPRISONING TROUBLESOME ROBBER BEES, AND PUTTING THEM TO HONEST WORK.

I applied the wire cone to use the other day that I am very much pleased with. Robbers got to work at a nucleus, and were raising quite an excitement. I made a box 3 x 3 inches, and as long as the width of the hive, with no bottom or back. The top was of double wire cloth, so they could not feed through it. Then in the front I bored a two-inch hole and put in a wire cone $2\frac{1}{4}$ inches long, pointing inside. This box I then fastened over the en-

ARRANGEMENT TO PERMIT BEES TO GO INTO HIVES, BUT NOT TO GET OUT.

trance of the hive being robbed, and you should have seen the robbers pile into that cone—just where I wanted them. Soon they were all in, *out of my way* in working for the rest of the day. I then took them back into the cellar for three days; and when put out they remained in that hive. So I not only helped the weak swarm, but got the robbers nicely cornered, and stopped their nosing around, and stinging, when every thing else might have failed. This plan may not be new, but I have failed to see it in print; and I give it, thinking it may do some one some good.

H. P. LANGDON.

East Constable, N. Y., Apr. 16.

Friend L., your experiment is quite old. As much as ten years ago I gave an account of it in *GLEANINGS*. I, too, got a lot of black robbers entirely out of my way; and by setting them in the cellar I made honest bees of them. They did not last very long, however. Either they lost their lives in undertaking to rob somewhere else, or else they were bees so old that they did not have very long to live. They lived long enough, however, to strengthen up my weak colony, so that the queen could fill it with brood. In my case, I presume that these black robbers came from the woods. If it were neighbors' bees, however, we should be careful about trespassing on any of their rights.

CARNIOLANS, AND THE POSITION OF GLEANINGS IN REGARD TO THEM.

By a late number of the *Apiculturist* and one or two of the other bee-periodicals, we note that one or two writers think the position of *GLEANINGS* is rather unfavorable toward the Carniolans. In fact, one scribe intimates that, because we sell Italians, therefore we condemn Carniolans. Why, the facts are, friends, we could sell Carniolans as well as Italians: At one time we were seriously proposing to locate a Carniolan apiary; but the few colonies we tested did not prove to be a desirable race to sell or recommend, and we thought we would wait for further developments. With us the Carniolans were not very gentle. The progeny of one queen were the crossdest bees we ever had in the apiary; but then, she may have been crossed with a black drone; but from the *looks* of her bees it was impossible to tell whether she was pure or hybrid. We also found that the Carniolans were disposed to swarm rather to excess. However, as we do not wish to appear partial we are glad to give a good word for them. In the last *Bee-keepers' Review* we find the following editorial:

THE CARNIOLANS GREAT BREEDERS.

This is the first spring that we have had several good colonies of Carniolans in a normal condition—that had not been exhibited at fairs the previous autumn. That they rear more brood early in the season than do the blacks or the Italians, there is *no question*. It was a surprise to us to see the enthusiastic manner in which they go at it; as though brood-rearing had filled their minds to the exclusion of all else. It makes no difference if no honey is coming in, and only a little remains in the hive, brood-rearing is kept up to the very highest notch until the last drop of honey is consumed. Even with our present cold, rainy, and late spring, three colonies of Carniolans swarmed May 23; and at this writing (May 27) the Italians have made no preparations for swarming.

We all like bees that get to the front early in the season—that “show up” with hives running over at the blossoming of the clover—but, unless these bees will “turn to” and gather in the harvest when it comes, our enthusiasm will suffer a rapid decline. In this latter respect, the Italians never disappoint us. When the harvest comes they are as completely carried away in gathering honey as the Carniolans now are in raising brood. If the Carniolans will gather honey, when it comes, with the same energy now displayed in breeding, they will be the bees for us; and it is with interest that we shall watch their behavior in this respect, and report results.

Perhaps we have not had fair samples of the Carniolans. We hope the majority of them are, however, better than those we tried. What we are all after is a race of bees to breed early, are prolific, good workers, and but little inclined to swarm, whether it be Italians or Carniolans. Beauty or color ought to be a secondary consideration.

FURTHER PARTICULARS IN REGARD TO THAT HEAVY LOSS IN NEW YORK.

You ask for a more definite report on my bees. I built a cellar, a honey-room, and a shop, 18x20—cellar full size of building, base laid in mortar, 6 ft. high, with drain under the base. It being so wet all winter, the ground in the cellar become very wet. I put the bees into the cellar Nov. 30; set them 10 in. above ground, three and four tiers high, with open bottom, and honey-board shoved part of the way off. It got very warm at first; then I opened the cellar door at night; left windows open all

the time, except shutters. It was very dark when the door was shut. The combs did not mold. I set my bees out Jan. 6, and Feb. 12 I left them out two days and then it turned cold, and snowed. I took 1000 lbs. of honey, top storage. I don't think it was the cellar, but the warm winter, and honey-dew. I will give you some of the losses:

	CELLAR.	LEFT.

These were all in cellars that have wintered well heretofore.

If you want definite statistics I will try to get them. There are others who have lost. It is wet, cold, and backward for bees. L. MARKLE.

New Salem, N. Y., May 22.

TOO SMALL AN ENTRANCE FOR THE CHAFF HIVE.

I like the Dovetailed hives to hive in; but with no bee-cellar to put them in for wintering, I will take the chaff hive all the time for the permanent home of the dear little bees. I have tested it, and found but one fault; and that is, the 8x% entrance is too small for hot weather, and I often have to raise the cover to keep the bees from clustering outside. I should like to tell you how much good Our Homes talks are doing, but I have not time. May God ever be with you. LUCINDA A. ZINN.

Philippi, W. Va., May 3.

We formerly made the entrance to the chaff hives only 8 in. long. Others have mentioned that this was too short, and our own experience convinced us as much. We have recently made the entrances full width of the hive, and we believe the change will be appreciated.

SELLING SECTIONS BY WEIGHT.

I object strongly to your statement that section honey is sold by weight. Everywhere I have been—Boston, New York, Washington, and even our own little local traders, invariably sell them (at retail) by the piece, no matter whether 12, 14, or 16 ounces, at the same price. I have no doubt that 99 out of every hundred retailers do the same thing all over the country. E. C. NEWELL.

Brookfield, N. H., Apr. 30.

Friend N., I do not know that I ever went into a grocery in any town or city where they sold sections as you say, without putting them on the scales. Why, the very idea of selling three-fourths of a pound at the same price as a pound, or even a pound and a quarter, seems incredible. Honey commands pretty nearly the price of butter. What would become of the grocer who would attempt to put off 12 ounces of butter for a whole pound? Perhaps we had better settle this question through the Question-Box.

LOSS IN MINNESOTA.

There was very serious loss in this county, from dysentery, caused by honey-dew. Some localities did not suffer so much as others. Colonies were left in very weak condition. While I lost but one colony in 40, I should estimate my loss in bees at 10 per cent. Others have lost 50 per cent in colonies, and 75 per cent in bees (estimated).

N. P. ASPINWALL.

Harrison, Minn., May 20, 1890.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

MARKET-GARDENING JUNE 15.

In my last I considered at considerable length what we should do with such a surplus of water as we were then having. Well, almost before my letter was in print it stopped raining and we have had warm sunshiny days almost uninterruptedly until the present time. I thought that, with the amount of rain we had had, we certainly could stand a couple of weeks, or even a month, without suffering. I soon found out my mistake, however. The ground had been so thoroughly soaked that our clay soil settled down about as hard as if it had never been plowed. Then when the drouth came, the ground cracked open until the cracks through the strawberry-bed were large enough and deep enough to drop strawberries—that is, little ones—clear out of sight. When a little rain came, the water just ran into the cracks and seemed to do very little good, comparatively. Our transplanted celery and cabbage did not prosper at all, unless the beds were heavily sprinkled with water from the windmill, and then loosened up by a sharp steel rake. This saved them, but it was almost more work than the plants were worth. Under the circumstances, about the only course is level culture, and plenty of soft mellow dirt. With the soft mellow dirt we can fix the ground so it would stand a drouth of two weeks, or a month, easily. The ground that was planted *before* the terrible rains, amounted to but little; I put in the potatoes as nicely as I ever did; but there came up a great wetness, and settled the clay down so solid it was like a brick. The potatoes tried to get up through the crust, but gave it up, and a great part of our potatoes on the creek-bottom land are *under the crust* yet. Cultivating between the rows fixes the dirt between the rows well enough, but it does not help that around the potatoes, so our first planting will be a failure. Ground that had *not* been planted was plowed up, rolled, harrowed, then rolled and harrowed again and again, until we had fine mellow soil. Corn, beans, peas, etc., planted in that fine mellow soil, without even a drop of rain, came up and grew to my full satisfaction. Without this fine mellow soil and perfect tilth, it is almost impossible to get a decent crop, no matter how much manure or phosphate or any thing else you put into it. To sum up the matter, when we have such heavy rains as we have had during the past spring, I do not know *what* to do. Does anybody else? True, we can wait until the rains are over and until the ground is dry enough to pulverize properly; but we shall have to go without early stuff. Sandy loam, with a gravelly subsoil, would probably help the matter greatly; but I fear that underdrains and overdrains are both inadequate for such severe rain-storms. We can, however, rejoice at the excellent prices. June 10 there was scarcely a strawberry in Medina, and whoever had them to put on the market could get his own price. We still get 20 cts. per lb. for

lettuce; 10 cts. for spinach and beet greens, There is another thing that I am rejoicing over: When every thing is exactly right, how wonderfully crops may grow and mature! Very few, in my opinion, have witnessed the possibilities of market-gardening and fruit-growing. We get glimpses, however, occasionally, and I am getting some of them now, and that makes me happy.

OUR HOMES.

If ye, then, being evil, know how to give good gifts unto your children, how much more shall your heavenly Father give the Holy Spirit to them that ask him?—LUKE 11: 13.

As it was children's day, and other matters occupied the attention of the Sunday-school, our lesson for last Sabbath was not taken up at all. But it has been taken up by me during the week, in a way that I have seldom before taken up any lesson. The golden text, "Ask, and it shall be given you; seek, and ye shall find; knock, and it shall be opened unto you," has always had something startling in it to me; and then the words afterward, about a child asking its father for bread, or for a fish, or for an egg. Would any *father* give a stone or a serpent or a scorpion? Surely not. And right close upon this vivid illustration comes the promise of our text to-day: "If ye, then, being evil, know how to give good gifts unto your children, how much more shall your heavenly Father give the Holy Spirit to them that ask him?" Please notice that, instead of saying that God will give bread, fish, etc., or needful food, the Savior says he will give us the *Holy Spirit*, implying, in a most positive and direct manner, that the Holy Spirit is the summing-up of all things. And the more I think of it, the more sure I am that the one thing needful to us all—yes, to every reader of GLEANINGS, is the Holy Spirit. If the Holy Spirit is in our hearts, it takes the place of every thing else. I have been so much impressed with this that I have been praying with unusual earnestness for that Holy Spirit in my heart, that is promised with so much emphasis. You will notice that, in all of Jesus' talk, in all his discourses, that seems to be the great theme. He is constantly exhorting us to more faith in God. Just before that part of the lesson which I have taken up, is a most earnest exhortation to importunity in prayer. This means, as I take it, that we are not to get *tired* of praying, nor to lose faith. We are to plead with God as we would plead with a neighbor who was unneighborly. Even though he should snub us, we are to have energy and perseverance, and faith enough to continue to beg and entreat and implore, even though he should say, right out, that he would not accede to our request. Now, we are to hold on to God's promises in the same way. We are to beg and beseech, no matter if we are discouraged by seeing only continual badness in our own hearts; and we are to continue to implore and plead for his Holy Spirit to take the place of the badness. What has been the result of my continued prayer for

the Holy Spirit in my own heart? Perhaps you may smile at the idea of my expecting an answer to such a prayer, when the prayer had been uttered for perhaps only a little more than a week back. Well, dear friends, I have become so much accustomed to seeing some answer to my prayers almost immediately that I have begun to take it as a matter of course—not when I pray in a half-hearted fashion, as a mere form, or as a sense of duty; but when I pray in real *dead earnest*, for any thing I feel is right and proper. I have been led to expect some sort of answer; and the answer in this case has been a little different from what I exacted it to be. This matter of the Holy Spirit has been for years rather confusing to me.

What does it mean? I have often before prayed for the presence of the spirit of Christ Jesus in my heart; and I do not quite know what it was unless it was our recent lesson that prompted me to use the words of our text, and ask the Father for the Holy Spirit. Well, the effect has been to give me more of a spirit of charity and love toward all humanity than I perhaps ever have had before; and I have also been able to see the consequences of a lack of faith and a lack of charity in others, in a way I have never seen before. Why, it seems to me, as I think of it this morning, that one of the greatest troubles we have to contend with is a lack of faith and a lack of charity in each other. The reason why many make *failures* in life, if I am correct, is because they are so constantly thinking evil of other people; and in the same line they doubt God's providence and God's promises, and almost think evil of the great Father above.

I want this talk to be helpful to you, dear friends, therefore I want to emphasize this uncharitableness by some illustrations that we all can enter into heartily. Uncharitableness is a disease. It gets hold of us, poisons our best feelings, warps our judgment, makes us sneering and ironical; distorts, twists, dwarfs, and cramps the whole universe round about us. The most prominent illustration I can think of in regard to bee-men is the false statements in regard to the adulteration of honey. The thing has crept in and grown until not only our periodicals but our standard works, our encyclopedias, and our medical books, have got the disease, and made a shameful show of the depravity of humanity where there is no such *depravity*. What a sad thing!

While Dr. Kellogg's book was on our tables a few days ago, one of the office hands turned over to the "Adulteration of Food," and there we found that foolish story repeated, about manufactured comb honey. Our good friends of the *Farm and Fireside*, in a lengthy editorial a few days ago, brought up the whole matter of adulteration of honey and the adulteration of candies, and ever so many other things, giving their readers the impression that humanity at large is so corrupt that we can hardly be sure of any thing. Now, this hasty, thoughtless manner of denouncing the great public at large—of denouncing the *business men* of our nation, all comes, if I am correct, because of a lack of the Holy Spirit; because we have

not that Christian love in our hearts that we ought to have, and that *strong reluctance* to repeat words of censure or reproach, that all of us ought to have. Oh, if newspaper men, magazine men, and publishers of encyclopedias, would, as they commence their work in the morning, pray from the heart that the Holy Spirit might keep them from these mistakes and evils, what a grand thing it would be! I suppose you have already thought of my bright little text right here—"Thinketh no evil."

A great part of my acquaintance with the world comes through the letters day by day—letters that I am obliged to read in order that I may do justice to my fellow-men. While most of these letters breathe a spirit of charity and love, there is occasionally one from a poor brother or sister who has got things mixed and wrong. He supposes he has been wronged and cheated, when nobody has had a thought of such a thing. How sad are such cases! I once had a teamster who was plowing on the creek bottom. He was right close by the railroad. His horses became excited, and made him some trouble with his plowing. He, poor fellow, became disturbed and excited too, and in his disordered state of mind he would have it that the *engineer of the locomotive* was running back and forth, sending the cars spinning hither and thither, just on purpose to annoy *him* and frighten his team. I had hard work to convince him that the railroad men never so much as thought of him and his team away down at the bottom of the bank. May be they did not see him at all; but he did not think it unreasonable or impossible that these men who handle great cars and locomotives, and whose time is worth ever so many dollars an hour, would stop and move great heavy machinery just on purpose to bother *him* with his comparatively *unimportant* labor. I often think of this illustration. Only yesterday Ernest wrote a whole page to a poor friend, to try to convince him that he was wrong in thinking that we had struck him a damaging blow in print, because we wanted to get the *business* away from *him* that he was doing. Why, the poor man did not even know that every member of the Root family have been wishing and almost praying for weeks back that the orders through the mails might stop. I presume I never would have mentioned it had not this circumstance brought it out. But, dear friends, I have actually felt pained when a clerk has opened a letter containing a hundred dollars, and sometimes two or three hundred. For so many years I have been in the habit of thanking God for such letters, that it *does* seem a little strange now to feel sad when they come. We have had more business than we knew what to do with. We have stopped sending out price lists and advertisements; we have discouraged those who inquired about goods—that is, hives and sections, because we knew how unable we were to fill orders promptly; and yet this poor friend would have it that we were greedy for the small business he was doing, and wanted it *all ourselves*. When by some blunder an advertisement was left out that should have ap-

peared, two or three good friends have almost insisted that A. I. Root kept it out because he was afraid it would injure *his* trade. And then when I have tried to explain, one or two have accused me of being untruthful. Why, bless your hearts, dear friends, do you think it possible, with all my cares and burdens, that I want what justly belongs to *you*? Think hard of me, if you choose, for our neglect during the past few weeks. You may even call me names, and accuse me of being lazy and half-hearted, and you may say I have got so I do not care as I once did; but, please do not hurt me any more by insinuating that I am *greedy for your business*. What a very sad picture I should present, if, after all these blessings God has sent me with such unstinted abundance, I should be greedy for still more property, more business, and more *anxiety*. Many of the things you, in your thoughtlessness, have accused me of, I never knew any thing about; for it is *impossible* that any one human being should be able to compass or keep track of so much. And in saying this, please do not understand me that *no one* is looking after your kind orders. Others have taken my place. Other good kind Christian hearts are reading your letters, many of them, and dictating answers in my place. Perhaps they do not *know* you as I do, and very likely they are so cramped for time that their answers are brief; but I am sure that a kindly feeling actuates them all. I am sure that the Holy Spirit has a permanent lodging-place in the hearts of the most of these friends and helpers who are gathered about me, doing their part to the best of their ability, and as I would do it if I were able to do it all.

During revival times we often witness the workings of the Holy Spirit in the hearts of men. A few weeks ago my old pastor, A. T. Reed, wrote me that he would be very glad to have me pass the Sabbath with him in a neighboring town, that I might assist him in the revival work now going on there. I could not well be spared for even one day, at this season of the year, especially at this present season; but I arranged to leave home late Saturday night, and to get home early Monday morning. Almost as soon as I stepped from the train Saturday evening, I was ushered into a church full of pleasant, wide-awake, earnest people. Their very faces inspired me; and I talked to them for forty minutes, perhaps, as well as I ever talked in any similar audience. Before the meeting closed, great numbers of young and old, especially the former, arose and testified for Christ Jesus. During the Sabbath I attended five different services, taking more or less part in all of them. I came home with a new inspiration in my heart for the cause. It was arranged that my stay over Sunday should be with a family who had lately come out on the Lord's side—at least a grown-up son and daughter had, and we hope and pray that the father will follow soon. The son and daughter were perhaps from eighteen to twenty, and I was at once impressed with the beautiful characters of the two. They were bright, enterprising,

go-ahead, remarkably intelligent, and at the same time their lives were consecrated to the Master. They especially won my respect and admiration, the more so, perhaps, from the fact that God had just called home the mother of the household. She died in March. In order to save expenses, and at the same time make the home pleasant for the bereaved father, the daughter had, with much zeal and devotion, undertaken to fill the mother's place in the household. The responsibility was a little new to her, and it touched my heart to see how anxious she seemed to have every thing pleasant for her guest, and to do as her mother would have done had she been alive. She did all the cooking and housework. Before the evening meeting she came out with a pleasant face, and called us in to supper. I replied, in a vein of pleasantry :

"Why, my good young friend, I did not know we were to have any supper, and it hardly seems as if we need any after our most excellent late dinner."

"O Mr. Root! is it really true that you mean exactly what you say? Did you indeed consider it an excellent dinner? You do not know how anxious and troubled I felt about it; and I was so afraid that I should not have every thing just right, or just as mamma would have had it."

As she spoke the words, a look of tenderness came into her face as she thought of the dear mother who had so recently gone; and it gave me, too, a glimpse of that anxious spirit which I had before seen beaming from her expressive hazel eyes. Had anybody asked me at the time what her complexion was, or what the color of her hair was like, I could not have told, for I rarely notice such things; but I should have said, notwithstanding, that she was one of the most beautiful characters (perhaps I might as well say *most* beautiful young women) that I had ever met. Now, please do not think that I am partial; for her brother was as handsome a young man as one often meets. The attraction in both was, however, in the line of "pretty is that pretty does." These two had recently given their hearts to Christ under the teaching and preaching of our dear brother Reed, who once, a few years ago, in God's providence, brought me from darkness into light. Brother Reed has grown since then, and God's work is growing rapidly in his hands. Some of you who see this, doubtless know him and have learned to love him. As his chosen field of work is evangelical, he may come into your neighborhood some time. If so, do not, I beg of you, miss seeing him and hearing him talk. Well, my heart was full of the Holy Spirit during this Sunday work. It was an easy matter to love everybody—even the ruddy-faced saloon-keepers that abound in such plenty in the town of Lorain. And is it any wonder that I had several times thanked God for giving me glimpses and even a brief acquaintance with two such nice people as this boy and girl I have been telling you of?

Of course, I recognized that they were human, like the rest of us—that close acquaintance might develop faults in their charac-

ters that seemed so perfect; but, dear friends, what is the harm of thinking well of everybody? My good old mother sees so much good everywhere in everybody, that it is a standing joke among the children. If she chances to talk with a tramp or a Jew peddler, she bids him good-by, with the firm conviction that he is a good man; and I know by experience that the tramps and Jew peddlers—in fact, almost everybody else, leave her with a feeling in their hearts, if not out-spoken, "Well, *there* is a good old lady, any way." Two or three times I have heard her called an old saint. Please excuse this much in regard to my mother, dear friends. It will probably be a long, long while before anybody calls this son of hers, who is writing to you, a saint or any thing approaching it. But is it not our privilege, dear friends, to see *saintly qualities* in our friends and neighbors?

Let us now go back to the neighbors I was speaking about—a boy and girl of eighteen and twenty—the two whom I had learned to consider almost as young saints—at least, during my brief Sunday acquaintance. Sunday afternoon, it being decoration day, I spoke briefly to an audience of several hundred. There were four or five speakers present, so we all spoke briefly. At the close of the talk, some old neighbors who used to live in Medina came forward and took me by the hand. As they lived near by, I was constrained to step into their home a few minutes between meetings. A young man—one of Ernest's old playmates—was among the converts, and the Holy Spirit had certainly found a lodging-place in his heart. The poor mother had not been attending the meetings, and she had not yet risen to that point where love, hope, and charity brighten and ennoble "our neighbors." I hope she will excuse me, if she ever sees this, for quoting one single expression from her talk. When they asked me where I was stopping, I gave them the name. They were new comers, however, and not much acquainted. Finally the mother spoke:

"Oh, yes! I know now. It is where that red-headed girl lives, who keeps house for her father."

Just then the words "red-headed girl" jarred particularly on my spiritual state. It is a common expression, and may be that almost any one has at times indulged in just such words. Dear friends, is it right to speak in that way of any neighbor? I had not noticed the color of her hair before, any more than to remember that it was light; and as she spoke feelingly of her love for Christ, her eyes were beautiful, and her face was beautiful, and her hair too. It seemed in keeping with her peculiar complexion. I noticed, as she sat down to the table, somewhat fatigued with her labors over the stove, a flush on her cheek. I knew what brought it there, and I admired her all the more. If there is any class of women I respect and admire more than others, it is those who voluntarily choose to do their own housework; who know what it is to cook and sweep, to iron and wash. The words "red-headed girl" kept ringing in my ears. They called up recollections of

times when I have thoughtlessly and unfeelingly spoken of my friends and neighbors with a lack of charity. May God help me to do so no more. May that Holy Spirit I have been telling you of help me not only to speak of, but to look upon every human being as something sacred and holy—as a piece of God's handiwork. And may this same Holy Spirit help me to see the good and saintly traits in fallen ruined humanity.

"O Lord God, help not only my poor self, but help every reader of GLEANINGS to pray often, in faith believing, for that Holy Spirit that Christ Jesus thine only Son promised to those that ask. Help us that the influences of the Holy Spirit may find such a lodging-place in our hearts that kindness and love shall characterize our every thought and word and deed; and may its influences brighten and ennoble our poor hearts that are so prone to wander after the bad. Help us to remember our sacred calling; help us, who have enlisted under the banner of the cross, to remember our profession; help us to see light ahead, and not darkness and ruin; help us to look up to the great God above, who created us in his own likeness and in his own image. Save us from the peculiar temptations that so often beset at least most of us, and which tempt us to see only the defects and misfortunes of the neighbors round about us; help us, O Lord, to see the God part, and inspire us with that Spirit, that we may be able to encourage and bring out the good; give us, we pray thee, of that Holy Spirit according to those unfailing promises, as in the language of our text to-day."

Come, Holy Spirit, heavenly Dove,
With all thy quick'ning powers;
Kindle a flame of sacred love
In these cold hearts of ours.

BUSINESS AT THE HOME OF THE HONEY-BEES.

SOME PRETTY SEVERE CHARGES AGAINST
A. I. ROOT.

DON'T be troubled, dear friends; it is not somebody else that I am going to complain of, it is only myself; and the particular reason why I speak of it is that I may ask you all to be slow in condemning your friends and neighbors, and to remember that there are almost always palliating circumstances that we do not know all about. In the past two or three issues I have told you that things were in a rather bad shape here this present season, on account of the unexpected rush for goods. Amid it all, however, we have tried to be prompt in answering all inquiries, and we have tried hard to tell the truth. I do not know that I have ever exhorted our clerks more, relative to making some sort of answer to every complaint that has come, than this present season. Notwithstanding, however, a great many of our friends have had great reason to complain, and perhaps good reason to say hard things of your old friend. The following letter illustrates this:

Dear Sir:—I write you once more concerning the supplies I ordered of you six weeks ago, which

have failed to materialize. After four weeks had passed I wrote you about the matter, and you claimed that orders had overwhelmed you so that you had been running night and day, but would ship my goods the next day (May 30).

After reasonable time for the shipping bill to reach me, I wrote again for the reason you failed to do as you agreed, and you failed to ship, or explain any thing. I have talked with several bee-keepers about the matter, some of whom are readers of GLEANINGS, and all agree that your promise to me of May 29, that you would ship my goods to-morrow, was a base deception. If you could not fill the order, say so like a man. My bees are swarming, and I shall get supplies elsewhere. A portion of the goods will be worthless to me before you get around, if you ever do. I demand my money back by return mail.

F. F. HARRINGTON.

Hartwick, N. Y., June 9.

Whoever undertakes to carry on a business requiring many hands, should take into consideration the fact that sickness and accidents will occur more or less, as a matter of course, and two or more should be trained, if possible, for the very important posts. The proprietor ought to ask himself the question almost daily, "What should I do just now if so and so should be sick or kept away?" This I have tried to do to the extent of having one or more "loose men" around, with nothing particular for them to do. This season has been no exception. I mentally wondered several times what I should do if a certain one were disabled or kept away, and in a very few days the very thing happened. Sometimes two valuable hands were laid up at once. During the very height of our rush I told my wife that nothing would make greater disaster than to have something happen to "John," who takes the entire charge of orders, and tells people what we can do and what we can not do. Well, John sprained his ankle at this very crisis, and was kept from the office nearly two whole weeks. But even when he could hardly endure the pain, the clerks were running to him with inquiries concerning business. This state of affairs threw our good friend Harrington behind, with a lot of others. Although Ernest was pretty well burdened with the journal matter, bees, and attendant letters, he took Mr. Calvert's place as best he could, and wrote the letter promising that the goods should be shipped May 30. He did this because "Jacob" told him they could surely go at that time. But there are other "big guns" in our establishment besides Jacob; and somebody overruled *Jacob's* ruling, it seems, and, in fact, in John's absence there were several who had been promised, and the promises could not well be all fulfilled at once. The postal card which friend H. says was not answered was answered promptly, but perhaps not as explicitly as the urgency of the case demanded. About the time the goods *did* go, I got hold of the transaction and declared that this shipment should be put on the next train, even if it stopped everybody else. Now, I do not know that even I had a right to say this, for a promise is as binding toward one man as toward another. It is true, that

although Ernest gave the positive promise that the goods would go promptly, they did not go until *seven days* afterward. Under the circumstances, friend H. was quite excusable in deciding that Ernest's promise was a "base deception." If he *knew* Ernest, however, he would never think of accusing him of trying to deceive anybody. Ernest is sometimes forgetful; but when he made the promise, he had no *thought* that it would not be kept. Now, I am very well aware, friends, that *apologies* are very well, so far as they go; but in cases like the above (and I fear there have been quite a number of them), the only thing that can be done is to ask these friends who have been "humbugged" by receiving promises that have not been kept, to make out their bills for damages. The only honorable apology, in my opinion, for such kind of business, is a *dollars-and-cents* apology. Friend H., make out your bill, and we will try to meet it. Meanwhile, A. I. Root begs that you will put out your hand with as much good grace as you can, under the circumstances, and "shake." Yes, even if we are going to quarrel, let us shake first; and if we can not shake *after* we get through, we shall be so *much* ahead any way. Hundreds of dollars have been already sent back, and a good deal of it just as soon as the letter was received, because the order was to ship at once or not at all; and we stand ready to return every dollar that has been sent us just as soon as we are told to, providing the goods have not already gone.

EDITORIAL.

Thou hast been a shelter for me.—PSALM 61: 3.

WHY DO THE BEES KILL OFF THEIR DRONES IN JUNE?

So many have asked this question during the past few days we have thought best to answer it here. I know of no other cause for such a state of affairs than a break in the honey-flow or pasturage; and, as a general thing, it indicates that you had better commence feeding until honey begins to come. If you do not, you will lose in brood in a way that will be damaging to your colony, even if you do not lose the colony outright by starvation. Watch the honey-flow, especially if you have colonies nearly destitute of stores.

HOW WE ARE GETTING OUT IN FILLING ORDERS AT THIS DATE, JUNE 13.

WELL, dear friends, we are still running night and day, with 500 or 600 orders ahead of us; but although the number of orders is large, the amount of goods to be sent is not nearly so great, for the orders are small, comparatively. We expect by July 1st to be up in every department. In fact, every thing now goes almost by return mail, or by return express or return train, unless it calls for hives and sections. Our wax-room is so well ahead they have come down to ten hours a day, so you can have any thing in the line of foundation right off.

QUEENS AT LOW PRICES.

We are well aware that queens are offered by different parties lower than we dare undertake to furnish them. Those ordering should remember, however, that we have for years been in the habit of having queens on our table every day, ready to be

sent out by the first mail. Now, at least some of those who offer queens at low prices do not send them promptly. Perhaps our readers know how many, better than we do. Another thing, those who order queens often live some distance from their postoffice. People write us about making a trip to the postoffice every day for a week, and that where the postoffice is three or four miles away. Imagine the trouble and expense it makes when the queens are not sent promptly. Another thing, those who are new in the business often fail in getting queens to go through alive. I fear that some of our younger friends have thoughtlessly figured up that they could do well in selling untested queens for 50 cents; but when they come to find, though, in experience, that half of them or more die before reaching their destination, they sometimes get into real trouble. Now, I do not make these remarks because I wish you to send your orders to us, but because I wish those who propose advertising queens at very low prices would think well and be careful before they embark in the business.

THE NEW WATER-CURE TREATMENT.

A HOST of letters have been received since our last; and the greater part of them—in fact, I might say all—who have purchased the secret of Dr. Hall speak in praise of this drugless remedy. Many give actual experiences of where it has been the means of saving life. They say, too, that before going to Dr. Hall, they had applied to our physicians right and left. If this is true, it is a rather sad state of affairs; but I can hardly believe that the average family physician is ignorant of remedies that have been laid down in our medical books, and even our common family doctor books, for ages. I am inclined to think that those good friends who have invested their \$4.00 are a little prejudiced against our doctors, and a little biased in favor of Dr. Hall. I am, however, well satisfied that even Dr. Hall's manner of doing business has been the means of saving life, and giving health to many more. Then is it not right for him to take \$4.00 from the sick and suffering for his little pamphlet? These friends I have been speaking of try to make out it is right, even though the treatment is in our common doctor books. Now comes the question, "What is right in such a state of affairs?" Why, it seems to me to be a very simple matter. All valuable information comes to us through books and periodicals. Let Dr. Hall give us a nice little book, fully illustrated, and filled with testimonials and experiences from those who have used this treatment. Sell this book at about the price similar books are ordinarily sold. By this means he will do a hundred times more good, and I think very likely he will get just as much money. I myself should be very glad to give the book a recommendation. I should like to have it, however, embody also the opinions of some of our leading physicians.

BEAUTY VERSUS UTILITY, AGAIN.

ON page 434 of GLEANINGS for June 1, in speaking of some yellow bees sent by Mr. Jacob T. Timpe, the type made us describe them as "yellow-banded workers." What we meant to have said was, "Five yellow-banded workers." Through the sickness of several of the clerks, the writer was obliged to attend to other work and omit some proof-reading. In this connection we would say that Mr. Timpe takes some exceptions to our having suggested in

this editorial the possibility that these four and five banded bees *might* contain some Cyprian blood. He assures us the bees in question are from pure Italian stock, and are *not* of Cyprian descent. In proof he sends another cage of bees which are indeed handsome five-banded bees. Though they resemble very closely some yellow Cyprians they are no doubt of purely Italian origin.

SENDING SPECIMENS OF FOUL BROOD BY MAIL.

EVERY season we have more or less such samples sent in paper boxes, which are often burst open in the mail-bags. The clerk who opens the mail sets the specimen in a certain place until the letter describing it is found. Then the one who examines it to see whether it is real foul brood or not may be careless. They ought not to be in our establishment, for foul brood has cost us already more than \$1000, clean cash. The point is, this sending of samples or specimens by mail or express, or any other way, should be stopped. It is very dangerous, and there is not a bit of need of it. We can tell you from description just as well as to see the brood itself; and our text-books and journals have all described it, over and over. Please do not send any suspicious comb through the mails or in any other way. Let all the bee-journals echo the request. If you are afraid it is in your hives, examine the description in our text-books; then if you are not satisfied, state the matter plainly; write to us or some other competent authority. Meanwhile take every precaution against spreading. It should be treated like scarlet fever, yellow fever, cholera, etc. Stamp it out of existence; and by no manner of means give a chance of spreading it by your own thoughtlessness or foolishness.

THE A B C BOOK.

WE have had a great many very kind notices of the A B C book, but never a kinder one, or one that we consider more complimentary, than the one made by Bro. Newman in the *American Bee Journal*, page 363. The following is the notice:

The A B C of Bee Culture, by A. I. Root, has again been revised and enlarged, and the new edition is now on our shelves. It contains 420 pages, and is profusely illustrated. It is the cheapest, and one of the best—if not the very best—of all the books on apiculture in existence. We congratulate friend Root upon the perfection and excellence of his book.

This is more highly appreciated, because friend Newman is not only the publisher of a bee-journal, but the author of a most excellent *bee-book*, and a practical printer besides. This state of feeling between publishers is indeed pleasant; and this is not confined to publishers of bee literature either. When G. B. Lewis & Co. suffered loss by fire recently, it will be remembered they received messages of condolence from other supply-dealers, with offers of assistance. As C. C. Miller said recently, it seems as if the millenium of brotherly feeling and good will were now among apiculturists. The *American Bee Journal* is always on time. We never saw one copy in all the hundreds that have come to us that was poorly printed—over-inked or under-inked. They are always a model in typographical appearance. We are in a position to know that it is not an easy thing to be out on time, nor to make every number of a periodical an exact duplicate of the others typographically. We do not say this because we desire to reciprocate friend Newman's kindness, but because it is something for publishers to emulate.

BEAUTIFUL BEES are always pleasing to the eye. GOOD QUALITIES are always profitable.

If you want Bees and Queens that combine beauty and good qualities to a *marked degree*, write for circular giving low prices. No circulars sent out unless applied for.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

Hybrid queens, 30c; mismated Italians, 40c; all young. W. W. KULP, Pottstown, Pa.

Six hybrid queens for sale at 30c each or \$1.00. L. WERNER, Edwardsville, Ill.

Mismated golden Italian queens during the season at 30c each, a rare chance to get some nice drones for next year's breeding. Address MRS. ISABELLA TREGO, Swedona, Ill.

Black and hybrid queens at 20c each, safe arrival guaranteed. Stamps taken, 2's, 5's, and 10's preferred. S. F. TREGO, Swedona, Ill.

Any one sending ready-provisioned cage can have black and hybrid queens in July for 20c. HENRY EARHART, Courter, Ind.

I have about 25 hybrid queens for sale at 30c each, or 4 for \$1, all industrious. Send soon to W. A. BARNHILL, Baird, Texas.

Four black queens for sale at 20c each; also a few hybrids at 30c. WILLIAMS BROS., Burdick, Ind.

Having a few colonies of hybrids to Italianize, we offer for sale 12 or 14 mismated queens for 50c each until sold. Some of the queens produce almost three-banded bees, and their progeny are almost pure Italians. T. L. THOMPSON, Blairsville, Pa.

During swarming season, mismated Italian queens for sale. Those producing worker bees part of which are black, 30c each. Those producing workers all with yellow markings, 50c.

J. C. WHEELER, Plano, Kendall Co., Ill.

FOR SALE.—25 nice, large, laying hybrid queens at 25c each. Send at once if you want nice ones. F. H. PETTS, Warsaw, Mo.

In Italianizing I shall have 30 or 40 hybrid queens to dispose of. Will sell 4 for \$1. Queens are very prolific. L. H. ROBEY, Worthington, W. Va.

Fine, extra-prolific hybrid queens at 20c each; 6 for \$1. Send soon, or off go their heads. Foul brood or other disease never known in our section. T. K. MASSIE, Concord Church, W. Va.

Mismated Italian queens 25c each, and blacks 20c, safe delivered. W. G. HAYEN, Pleasant Mound, Ill.

I have 50 hybrid queens for sale at 25c each. A. HINES, Independence, Ia.

SECTIONS, \$3 PER 1000.
Foundation, Alsike clover seed, and Japanese buckwheat, cheap as the cheapest. Special prices to dealers. Send for our FREE PRICE LIST. M. H. HUNT, Bell Branch, Mich.

PLEASED WITH THE A B C.

You are right in thinking the A B C of Bee Culture would suit me, for it does, and I am more than interested in it.

W. B. HAMILTON.

Quincy, Miss., May 26.

PRINTED SERMONS.

I am kept very busy now in Christ's service. I am superintendent of the Sabbath-school, class-leader in the church, president of the Band of Hope, and also take the service in the church now and then; and sometimes, when I get to reading your Home talks, I feel as if I should like to shake you by the hand, and say, "Go on, brother; you are doing a grand work for the Master, the result of which only eternity will reveal." I only wish that all the papers that are printed would tell us more about Jesus. It was by reading a sermon by one of your ministers, T. Dewitt Talmage, that I was brought to a saving knowledge of the truth, and that sermon was in a newspaper. A. A. MILES.
Brisbane, Australia, Feb. 10.

[Dear friend M., we rejoice to know that one of our American ministers, through a printed sermon, was the means of bringing you to the Savior. I want to thank you for your frank acknowledgment. May the Lord be praised for such testimony.]

OUR LEADER SHEARS.

About Christmas time I ordered a pair of your Leader shears, also a pair of lace scissors, both of which have proved more than satisfactory. The shears are beautiful. A number of my friends have seen them, and thought them wonderful for the price. MRS. F. M. MAYNARD.

Jefferson, Wis., Mar. 29.

[My good friend, perhaps I should say to you and a good many others who have been rejoicing over the price of the Leader shears, that the factory where they were made has been burned down, and has not yet been rebuilt. On this account we are out of some of them, and have been obliged to substitute others. We purchased, however, so large a stock that we have enough to last for some time to come, with the exception of a few sizes, such as the 6½ and 10 inch.]

HONEY COLUMN.

CITY MARKETS.

KANSAS CITY.—*Honey.*—Received to-day first consignment of new comb honey from Independence, Mo. Very nice white 1-lb. sections, put up in handsome whitewood packages, twelve sections to the case, selling at 15@16; no change in extracted. *Beeswax*, 25.

FOR SALE.—An apiary of 125 colonies of Italian bees, together with fixtures and honey crop, if bought soon. I will also sell my place, good house and out-buildings, and 8½ acres of land. L. WERNER, Edwardsville, Ill.

CARNIOLAN APIARY FOR SALE!

My Carniolan apiary must be sold at once, to allow me to move to Colorado Springs.

"You have the best Carniolans in the country."

H. ALLEY.

Select imported queen, \$5; untested queen, \$1; untested, ½ doz., \$5; tested queen, \$4; 1 lb. bees, \$1; 3-frame nucleus, \$2.00; full colonies, in 1-story Simplicity 9-frame hive, \$5; add price of queen you want. Ten per cent discount on all orders of \$20.00 or over. Large stock of all ready to ship at once. Queens by mail, others on board cars here by freight or express, as ordered. Remittance of currency, bank draft, or money order must accompany all orders.

Will sell my whole apiary and implements, and give immediate possession. House and grounds also for rent.

S. W. MORRISON, M. D.,

Oxford, Chester Co., Pa.

In responding to this advertisement mention GLEANINGS.

WE have on hand a fine lot of beautiful Italian queens which we will send by return mail at the following prices: Tested, \$1.25; untested, 85c. Safe arrival guaranteed. LEININGER BROS., Douglas, Putnam Co., Ohio.

Queens by Return Mail.

Untested (Italians)	\$1.00
Tested	1.50
Select tested	3.00
Untested honey queen	1.25
Tested honey queen	1.68
Select tested honey queen	3.75

Bees and brood at the same rates. See our catalogue, free on application.

A. I. ROOT, Medina, Ohio.

IF YOU WANT BEES

That will just "roll" in the honey, try **Moore's Strain of Italians**, the result of eleven years' careful breeding. Reduced prices: Warranted queens, 80c each; 3 for \$2.00. Strong 3 L. frame nucleus, with warranted queen, \$2.50. Safe arrival and satisfaction guaranteed. Those who have never dealt with me, I refer to A. I. Root, who has purchased of me, during past ten years, 415 queens.

POLLEN FOR BEES.

CAN BEES GET ALONG FOR ANY LENGTH OF TIME
ON NITROGENOUS FOOD?

SOME years ago I discussed, in *GLEANINGS*, P. Schoenfeld's theory on the larval food of bees. Mr. Schoenfeld has published in the *Illustrierte Bienenzeitung* some other very interesting articles, which I am willing to reproduce in *extenso*.

DRONES.

About three years ago Schoenfeld inclosed a frame with new combs in a cage of double wire cloth, so that the bees outside of the cage could not feed those inside of it. The comb was filled with 100 gr. of sugar syrup, and then a number of drones put inside of this cage, and the whole thing was hung in a good colony of bees. At the end of the third day the drones were dead. Two other experiments on cold rainy days, when no drones were flying, had the same effect. It is well known that drones feed themselves on honey. If we cage them and give them a few drops of honey so soon as they are hungry, they eat this honey like the worker-bees. Schoenfeld then caged some drones in the same way, giving them honey instead of sugar syrup, and they died at the end of the third day. Next he removed the outer wire screen, so that the worker bees could feed them through the single wire screen, and they lived for weeks. Consequently, drones can't live longer than three days, if not fed with nitrogenous food by the workers. I will remark here, that it is a well-known fact that drones, as well as queens, feed themselves on honey, but do not eat pollen, but are fed by the worker bees with the same nitrogenous food which they give to the larvæ. These experiments prove this again, so far as drones are concerned.

These experiments indicate how the drones are

killed by the worker bees in the fall or summer time. It was supposed, till recently, that the worker bees drive them from the honey at first to the bottom-board, and, when weak enough, they are carried out of the hive. But the drones are not so lazy and awkward that this could be done without great tumult. It is much easier to explain, if we know, that the drones get very weak soon after the worker-bees stop feeding them nitrogenous food.

But these experiments throw some light on another question: Why do the bees kill the drones? It was supposed that the drones are expelled as soon as the swarming fever is over, and no mating of young queens would be necessary; and because queenless colonies keep drones, sometimes, over winter, this doctrine seemed to be infallible. But not to speak of the fact that such a knowledge is far more than we can expect from the mind of an animal, we know of some facts against this theory. If this theory were correct, the bees would kill the drones as soon as the last swarm is cast; in many localities they do not do so. Here in Texas the bees swarm in March and April, in May and June we have our main honey-flow from horsemint; as soon as the horsemint is drying up (about July), the drones are killed; in the fall we have some other honey coming in, and other drones are raised; but I never got a swarm in the fall. It would be interesting if Mr. Poppleton would tell how the bees do in this respect in Cuba.

We can easily see that, as soon as the pollen in the field commences to get scarce, the production of the larval food is becoming more difficult by degrees. At first the drone brood is fed no more; then the drones, which die in a very short time. This is sometimes quite sudden, if in springtime a frost or in summer a hail destroys all the blossoms.

That queenless colonies keep their drones is not

against this theory. These colonies have no brood, but have pollen in abundance, so the drones are the sole consumers of all the larval food instinctively produced by the bees.

But we can learn something more by these experiments. A food necessary for drones will be just as necessary for workers. Worker-bees, it is true, are much more hardy. Without any food, drones starve in six or eight hours; but workers stand this treatment for 48 hours. Nevertheless we can see that the worker-bees, too, need some nitrogenous food to preserve their vitality; i. e., they need some pollen. Every bee examined in the first months of the winter, when no brood at all is in the hive, will show many pollen-shells in the alimentary canal. If the bees have no pollen in the cells they find some in old combs, and the experiments made with sugar syrup are no proof that the bees can live without any nitrogenous food, we will say, during the winter, because the sugar is not quite without nitrogenous matter. Some pollen in winter is not only without danger, but it is necessary. I may add to this, that the so-called "pollen theory" may be explained in another way. In some localities the bees may bring in so much pollen that a great part of the cells are full of pollen covered with some honey. Hereby the bees not only starve, but they will get too cold in winter time. The cluster of the bees is always on empty combs, and in every cell inside of the cluster is a bee, so long as the cluster is compact. If the most of these cells are filled with pollen, the cluster is too much expanded, and the bees have to eat more to keep it warm. In this way an abundance of pollen in the brood-nest may be dangerous in winter indirectly.

Some bee-keepers doubt that the bees go inside the cells inside of the winter cluster; but if we take into consideration the fact that the comb is about one inch wide, while the space between the combs is hardly half an inch, we see that, inside of the cells, is room enough for double the number of bees in the space between the combs. If these combs would be empty in the cluster, it would be hardly possible for the bees to keep up the high temperature, while outside we have some degrees below zero. The cluster would by no means be a compact one. But it is hardly necessary to talk about, if we take into consideration to what small a cluster a colony is contracted in cold weather, which colony, a short time before, covered the spaces of eight or ten frames.

Selma, Texas, April, 1890. L. STACHELHAUSEN.

On receipt of the above we forwarded the same to Prof. Cook for his opinion and experience on the matter, and he replies as follows:

Mr. Stachelhausen's article is certainly very interesting. I believe he is largely, if not wholly, correct in the matter of drones. I think the drones get their albuminous food from the workers. They, the drones, work hard functionally, and so need much of this food, and soon die without it.

I do not think the workers need as much nitrogenous food as Mr. S. thinks. They must have, it is true, albuminous food, but there is enough in the blood and tissues to last them for days, and weeks even, when they are not active. Cage bees, or let them be in the quiescent condition of winter, and they gather nothing, and feed no brood—are, in short, nearly idle. Thus they survive and do well

on honey or syrup alone—just as we may be sick, and live for days, perhaps weeks, without any food other than water and air. I am very certain that our friends in Germany, or some of them, magnify the importance of this food in winter. I do not believe the queen gets any, and I doubt whether the workers do for weeks together. Of course, as soon as the queen commences to lay, then the bees eat pollen, and feed the digested food to the queen. As soon as I can get time, I shall write up my experiments, made last winter, in keeping bees without pollen. I think these experiments will sustain the position I have taken. A. J. COOK.

Agricultural College, Mich., June 11.

It seems to me that friend S. has given us some suggestions that have never before been brought forward, and some that are most undoubtedly true. It never before occurred to me, the injurious effect a large quantity of pollen might have in breaking up the compact cluster, so necessary to successful wintering. But since he mentions it, I do believe that the presence of so much pollen in the brood-nest is often detrimental in just this way.

RAISING QUEEN-CELLS WITH A CAGED QUEEN.

CAGED QUEENS OR REMOVED QUEENS—DIFFERENT BEHAVIOR.

I THINK I have seen it stated that bees with a caged queen will raise queen-cells just as readily as if the queen were removed. In nearly every case, before this year, I have had queen-cells started when a queen was caged, but not in such large numbers as when a queen was removed. The bees seem to think their queen, though present, is failing, and act as in the usual case of superseding an old queen. There is one marked difference in the conduct of the bees between caging and removing. When a queen is caged, all the eggs in the hive are hatched, and the brood reared; whereas, in the case of removal, the bees destroy, as a general rule, if not always, all the eggs. I think I have never seen this mentioned, and it seems strange that, at a time when one might think every egg would be cherished, they are all destroyed. I don't know what the bees do with them. I have read about bees eating eggs, but I am a little skeptical; for, if I mistake not, I have seen eggs left in a hive after a colony had starved in it. As I have said, the caging of a queen starts bees to rearing a queen or queens as in superseding. Toward the last of May, this year, I caged a number of queens on purpose to have queen-cells started. To my surprise, most of the colonies did not start a cell. I suspect it was because the bees were very short of stores, for I have been obliged to keep close watch to keep the bees from starving, the weather having been so bad that I think there was not over two days' work on fruit-bloom. June 3, with plenty of clover bloom in sight, but hardly old enough for bees to work on, many hives had not a cubic inch of honey in sight. Frames of brood, put in an upper story over an excluder, shared the same fate; in most cases not a cell was started. Probably if I had fed a little each day, the result would have been different. In making the above experiments I was surprised to find

QUEENS STOPPED FROM LAYING BY USE OF EX- CLUDERS.

In three cases I put all the brood of a colony into an upper story, leaving the queen in the lower story with an excluder between. I expected, as they were strong colonies, that enough bees would stay above to take care of the brood, and that the queen would go right on laying in the combs below, which were in good shape for immediate use. Two days later not an egg was laid in either of the lower stories, although there appeared to be a good many bees with the queen. In two of the hives I then put a frame of brood in the lower story, and the queens went right to laying. In the third hive I made no change; and ten days after the queen had been left broodless there were only eggs below, showing that the queen had stopped laying at least a week. Not a queen-cell, however, was started above.

HOW SOON QUEENS LAY AFTER CAGING.

In caging queens during the honey harvest I found that a queen, after being caged, did not immediately commence laying after being freed. The longer she had been caged, the longer she was without laying after being freed; in some cases, I think waiting about a week before laying. But this spring, just as soon as freed, a queen commenced laying. They were, however, caged only about a week, in which case I should expect, in the honey harvest, at least a day or two to elapse before the queen laid. Why the difference? Was it the season of the year?

A SPACER SUGGESTED.

As so many are suggested, I'll tell you one I'd like to try, but, oh dear! I'm so crowded in the busy season that it isn't likely at all I can try it; but some one else may. I think it may be very old. Get a furniture nail whose head projects $\frac{1}{8}$ of an inch, or a square block of wood of the same thickness, and drive into one side of the top-bar at one end, just over the end-bar. Put one on the opposite side at the other end, and your spacing is complete so far as the frames are concerned. The dummy must be treated the same way (for I imagine a dummy is important with fixed distances), and on each side of the hive must be a spacer where there would be one if a frame came in place of the side.

VERTICAL VIEW OF HIVE, DUMMY, AND THREE
FRAMES WITH SPACERS.

To make it more satisfactory, I think a spacer should also be put about half way down the end-bar.

C. C. MILLER.

Marango, Ill., June 4.

My dear friend M., I am surprised to hear you say that bees as a general rule destroy all the eggs after the removal of the queen. Some time ago, somebody suggested that a

great part of the eggs were missing shortly after the queen was taken away, and gave as a reason that the worker bees had eaten the eggs in order that they might have the wherewith to produce the royal jelly. So many objected, however, that I believe our friend gave up his theory. Now, I do not know that I ever saw a case where I thought all the eggs were removed after taking out the queen. On the contrary, I have often watched the eggs to see how many days would elapse before they were all hatched into larvæ. So I feel certain it can not be a general rule, with our bees any way.—I am very glad indeed to know that you have noticed the difference between caged queens and removed queens. Yes, I have often noticed that queens are usually idle some little time after their laying has been interrupted.

JONES VS. BROWN.

THE LEGAL ASPECT OF THE CASE.

I BEG to dissent from the decision of your "court of equity" in the case of Jones vs. Brown. I look upon the decision as involving a great deal. If left as a majority of the judges have decided, it will have, it seems to me, a decidedly demoralizing tendency, and will virtually abolish the business of letting out bees on shares. It will tend to weaken confidence, vitiate contracts, and absolve responsibility.

The contract in this case is, as stated, that "Jones and Brown have been keeping bees on shares. Jones is the owner, and Brown is the apiarist. They agree to share equally in the profits and in the expenses." The result is, that, "during the following winter, three-fourths of the bees die." The question is, "Shall Brown stand half the loss?" In the absence of the statement, the inference is "that the death of the bees occurred within the time limit of the contract."

A majority of your "best authorities" on bees find for Brown—though in an indefinite and irresponsible way. Custom often becomes—or, rather, makes, law. Sometimes, however, equity is law. If this case is to be tried under the former, then it must be ascertained what custom is. If by equity under the common law, then I would reverse and remand their decision, upon the following grounds:

1. Jones furnishing the factor, capital, and Brown the factor, labor—the third and last factor, land, not entering into the firm; and agreeing, under the contract, to "share equally in the profits and expenses," they become equal partners in the business for the term specified in the contract.

2. The stipulation that they were to share equally in the profits and the expenses is a sufficient provision in the contract to cover the liability of loss in wintering.

3. Under the contract they were equal owners of the apiary for the time being; and, as equal owners, are equally interested in all usual or unusual profits, and so, also, of all unavoidable losses. If, however, the loss could have been avoided by Brown, then Brown should stand, as C. C. Miller says, "for the resulting damage; not sharing the loss, but paying all the loss."

Bees, standing for money—and both are capital—should have been accounted for by Brown the same as if the money had been given him. If

money, by Brown's reasonable care, had been lost, the loss should have been borne equally; but if by Brown's negligence, maliciousness, or dishonesty, he, then, of course, should be responsible for, not half, but *all* of it.

4. Jones furnished the bees, and Brown the labor; Jones's superintendence and responsibility then ceased, and was assumed by Brown; and it would have been wanton interference upon the part of Jones to concern himself further with the business. Advice, even, would have been purely voluntary.

5. Brown's skill or capacity to care for bees has nothing to do with the matter. It was not needful for Jones to know of them, under a private contract, any more than under a public bid under the hammer. All Jones needed to be interested in was Brown's ability to meet a money obligation.

6. "If the bees," says friend Wilkin, "did not make honey enough during the season to keep them over, it should be the owner's loss." Exactly; but are not both parties the owners for the time of the contract? Would it not be better to say, that, "if the bees did not make enough to keep them over, the firm should have bought sugar for Brown to feed them, and thus divide the loss only of sugar, and save the loss of the bees"?

7. Mrs. Harrison and George Grimm gave the best answers, both worth repeating. She says: "Ordinarily a share in the profits would imply a share in the losses, there being no provision to the contrary." He says: "Under the given state of facts, each must stand half the loss, even if not occasioned by the carelessness of Brown." I would amend by adding, "And if occasioned by the carelessness of Brown, then Brown should stand it all."

This matter being of much importance to the fraternity, it is seriously to be hoped the final decision may be correct.

You have done the public great service in exposing Dr. Hall. I will have your article copied in the newspapers. Thousands of dollars go to Hall from Texas every month.

J. L. CALDWELL.

Mart, Texas, June 14.

Friend C., I am exceedingly obliged to you; in fact, I have been wishing for some time to have some lawyer speak out; and I am very glad, too, for your opinion in regard to the Dr. Hall matter. I only wish that some of our doctors would speak out just as freely; but some way or other the whole brotherhood are perfectly silent on this great discovery of doctoring without medicine. Is it really true, as Dr. Hall says, that they are all bitterly opposed because it would cut off their bread and butter? You know, of course, I do not believe a word of it; but what in the world is the reason that all of them keep still?

AGE OF BEES TO GO WITH QUEENS IN SHIPPING THEM, ETC.

FRIEND DOOLITTLE TELLS US HOW TO GET BEES OF THE RIGHT AGE.

A CORRESPONDENT writes, asking whether there is any difference as to age of bees which are placed in the cage with a queen for shipment, or whether an indiscriminate catching of them will answer every purpose. I have made the sending of queens by mail a study for many years, and find that there is a difference in regard to the bees that go with the

queen. I have used bees that were all old and those that were all young, with poor results. To illustrate: A party ordered three queens. In one of the cages, all old bees were used to go with the queen. This cage was marked with a private mark. My circular states that I guarantee the safe arrival of all queens, on the condition that, when the cage arrives, the bees be carefully examined through the wire cloth; and if the queen is dead, the cage is to be returned to me with contents unmolested, when I will send another. I made it thus, partly to guard against fraud, but mainly so I could look into any failure on my part in meeting the right requirements for perfect shipment, as I could often find the clew to the failure, in the returned cage. The candy part was the main trouble in former years; but that has been fully overcome by the Good candy and its modification. From this digression by way of explanation, let us return to the three cages.

One was reported as arriving dead, and was returned, while the other two came without a dead bee. When the returned cage arrived it had the private mark on it. Again, in early spring I often have to use bees too old for the best results, where the queens are taken from the hives lately set from the cellar, unless I take bees to go with them from hives that were wintered on the summer stands, they having bees of the right age. As it is some trouble to get these bees from another hive, and as such bees sometimes have a desire to worry a strange queen, I sometimes take the bees that have wintered over from these cellared hives, and send them along; but the loss has been so great that I have resolved never to do it again. I also find that very young bees will not endure the journey any better than old bees. Sometimes in forming nuclei by setting a laying queen with the bees and frame of brood she is on, into an empty hive, as I have given in GLEANINGS, and sending the queen off two or three days afterward, a few had only young fuzzy bees left, as the older ones had returned to the old stand. Cages so sent with young bees, and marked, have gone with many dead bees, where they were not returned as altogether bad. In this way I have watched results till I have found that bees from six to fifteen days old are the ones that stand the journey best, especially if a long one, like going to Texas, California, or to Washington, were to be taken.

Having learned what bees to select, I now rarely lose more queens in going to these distant points than I do when the distance is 500 miles or less. In selecting bees, take those that have flown a day or so previously, and not those whose bodies are distended with excrement, as all young bees that have never flown are extended to a greater or lesser extent, with the pollen consumed in their larval state. To know what bees to select, I am often guided by those which thrust their heads into the cells of unsealed honey first; and, besides this, bees in this position are very easily picked off the combs, as the wings stand out from the body. The item of having queens reach their destination in good order every time is quite an important one to the queen-breeder.

THOSE LONG-IDEA HIVES.

On page 318 I see it is desired that I tell why I did not stick to the "Long-Idea" hive after obtaining so large a yield of honey from it. There were three reasons why I gave it up: The first and greatest of

which was, I could not winter bees in them. The bees died in them every winter during the three years I tried them. The second reason was, that, when taking out the combs for extracting, the back must be bent all the while or else the hive be set on stilts, and then the bees ran out all over the sides of the hive, so as to make much work in closing it, instead of going below, as they do in a two-story hive. The third reason was, that, the last season I used them, colonies worked in two-story hives gave a little more honey than did the Long-Idea hives, one giving over 400 lbs., while the Long-Idea was some 28 lbs. short. I might also add, as a fourth reason, that I found that there was more money to me in comb honey than extracted, and the Long-Idea hive was never intended for comb honey.

G. M. DOOLITTLE.

Borodino, N. Y., June 14.

Since you suggest it, friend D., it occurs to me that my custom in getting bees to go with the queen was always to take those with their heads in the cells, sucking up honey. One reason for so doing was that I might get bees having honey in their sacs, to feed the queens.—Thanks for your answer in regard to the Long-Idea hive. Your third reason is rather a stunner. But I do remember that a great many at one time reported enormous crops of honey from those Long-Idea hives.

OSBORN IN CUBA.

PROPRIETOR OF OVER 500 COLONIES.

Friend Root:—Our drouth is at an end. For six and one-half months we had no rain, three little showers being all. Is this common for Cuba? They say it is not. In 1840, so the records show, they had a drier year than this has been. For eight months it did not rain; and you can set it down for a fact, that I hope we shall not have another drouth in fifty years to come. How did our bees live through the last six and one-half months, when there was not a flower or a green blade of grass—nothing but dust, dust, and dry leaves that you could see, as far as the eye could reach? Now, did I not tell you that I had unbounded faith in Cuba and its honey resources? Well, the last six and one-half months has been a test of that assertion. But, *how* did they live, from our apiary in the east and south and west too? From two to six miles away (as the crow would fly), there are small lakes and creeks and large bodies of wet land covered with all sorts of timber and vegetation common to a tropical country. These regions furnish an immense amount of bee-pasturage that is not materially affected by dry weather. To such places our bees went for their rations, when there was not a single flower near home. Now, such a season as this has been is what I call a practical test of the *honey* resources of Cuba. You know that assertions amount to but very little, and misdirected efforts do not prove to be false what I have stated before; i. e., that at this day in Cuba it is practically impossible to overstock a range. The time may come when the conditions will be so different from what they are now that overstocking will be possible, but it is not now.

I wish to correct one statement you or Ernest made when you said "Osborn had charge of seven or eight hundred colonies." That was a mistake.

I never was in charge of so many colonies for any one. The most I ever had was in the fall of 1885. I had charge of 586 colonies for the Casanova brothers; and now that I am running my own business I have 526 colonies, and I think that, next spring, I shall increase them to 600, all in one apiary. I know that to many, yes, to very many readers of GLEANINGS, 600 colonies seems too many for one apiary; but if they will stop a moment to consider the cost of starting even a small apiary here, they will make up their minds that more honey can be secured from 600 than from 250, and one outfit will answer for the whole; and during the bellflower season, I tell you 1000 colonies in an apiary can not gather the honey. But in summer the poorest of them would have to be helped.

QUEEN-REARING.

We are requesting our apiary now; and while upon this subject, I must say a few words upon the subject; i. e., *young queens vs. old queens*. I know friend Doolittle has just written an article condemning the practice of superseding queens two years old; but for this country such a practice (that is, letting the queens live as long as they seem to be doing well) would ruin any man that followed it, for more reasons than one. Chief among them is, our honey-flow comes at an unreasonable time of the year—at a time when the bees prefer to be at rest. Now, then, if you have not young and vigorous queens that will lay and keep the hives full of bees at a time of the year when an old queen would lay hardly enough to furnish bees to take care of the combs, any one can see at a glance that such bee-keeping would not pay for Cuba. Then, again, an old queen begins to fail in more ways than in the decrease of eggs she lays. The bees that hatch from eggs of the old queen are lacking in vitality. You may go into her brood-chamber, and you find it quite well filled with brood; but her bees die young; they do not live to do much work; they lack vitality; they lack longevity, ambition, and push to go after the honey. Most of the above are the characteristics of the progeny of the old queen. Does the rearing of queens have any thing to do with it, for better or for worse? Yes, much, very much; and now I want to say again that I have yet to see or hear of a better mode of rearing queens than by the horizontal-bar process, when all conditions are favorable. This principle I found in GLEANINGS, I think, in 1877. I can not remember the one who first used it. But I have used it for thirteen years, and have never seen a good reason to abandon it. No, not any queens over two years old for us here; but in California I have had them live to be five years old, and do good business up to four years, but not here, for they lay so continuously that they exhaust their fertility long before they are four years old.

Now, friend Root, if you have any objections to raising queen-cells on horizontal bars, tell me what they are and I will see whether I can meet your objections with reasons backed up with a long and successful experience. I shall say, "No, I do not want

CLOSED ENDS AND WIDE TOP-BARS."

If, with the narrow end and top bars, brace-combs must come, why, then so be it; but deliver me from a frame that you have to have a beetle and wedge to get it loose when you want to.

THE OLD SIMPLICITY VERSUS THE FLAT COVER.

You say you do not see how we keep the bees

from building up on top the combs, with the old Simplicity cover (unless we have a cloth over the frames). Well, we do have a cloth, and the best cloth I ever saw, made of old sail cloth that we buy in Havana at a reduced figure, and I have yet to see anything that equals it for a bee-cover. But with all that, they will eat holes through and go up and build comb, and fill with honey; and when they get it nicely full we take it off and put it on to some young colony that is building up, and have not sufficient workers to gather plenty; and, don't you think that young colony will go ahead with that much honey stored in the garret? I think it will. That is not all. During the summer the colonies get very strong, and long in the afternoon you will find the cover packed full of bees that seem to be up there taking a nap. Just before dark, go and quietly take the cover, bees and all, and place it on some young colony where the queen has just commenced to lay. During the night they will work down among the combs, and it may surprise one who has never tried it, to see how many of those bees will stay where you put them, and work right along as though they had swarmed naturally. But I am not done yet. If they do not wish to stop to eat holes through the cloth, they just get their shoulders under that cloth, and they raise it up and build under it on top the frames; then what? do we cut it off? No, not yet, but put it into the extractor and throw it out, and sometimes we wish the comb were still higher, as it would hold more honey. We let them go that way until the last time extracting (then we are not in so very much of a hurry), and we clean them all off, and have a fine lot of wax. Now, suppose we stopped to clean those frames every time we extract; it would be a losing game, besides the time it took to do it. The first hard work the bees did would be to put it back again; therefore a double loss. Can you now see why I like the old Simplicity cover?

EXTRACTORS, AND GEARING UP.

You do not see why I want the baskets to make five revolutions to the crank one. Now listen and see whether I am correct or not. You take a two-frame extractor with an 18 or 20 inch can, and you

A HONEY-EXTRACTOR FOR USE IN CUBA.

can throw out honey quite well (even without any gear); then you take a can that is 3 feet or over across, and try it without its being geared, and see what the result will be. I think that, by the time you have extracted a few tons, you will think you would rather have it geared, and geared high too. You know that, as you go from the center you de-

crease the centrifugal force; so it naturally follows that, to produce the desired results, you must make up in rotary speed what you have lost in centrifugal force by increasing the distance from the center-shaft. These are facts, as you can easily demonstrate by a trial. With this Stanley we have here, it has a graduated crank (that is, you can make it short or you can lengthen it to make the purchase greater), so if the baskets make five revolutions, more power will be necessary; but with the increased length of crank, one can be made to balance the other, and it really will be much easier than the slow motion; for you know that, with increased leverage, you can overcome what has been added, by an increase in motion, and not make your hand go around so fast either.

In relation to your visiting Cuba, do come; come and spend a winter in the finest climate, from October till May, you ever saw. The showers—well, during the summer months, it is not uncommon for it to rain every day or half a dozen times—just those showers you speak of; but in the winter, no. In the months of November, December, January, February, and March, and many times April, it is not common to have much rain—a shower, perhaps every week or so; but the winter is called the dry season; but this last winter, of course, has been the great exception. That the climate is fine here in the winter, there can be no question.

A. W. OSBURN.

Punta Brava de Guatao, Cuba, W. I., June 3.

We are very glad to learn, friend O., that you not only manage, but that you are the proprietor of 500 colonies. What you say in reference to your locality, and its capacity to support 400 or 500 colonies, is no doubt true. What we might call great overstocking in the Northern States might with you be considered understocking. There is a great deal of nonsensical twaddle about "locality" affecting conclusions, drawn by different apiarists; but when it comes to the matter of overstocking, locality certainly does make a very great difference. Some places may not support more than 50 colonies; still others 200, and even 500.—In regard to closed-end frames, do not get the impression that exact spacing is absolutely necessary for the prevention of burr-combs. All that any one can claim for it is that it assists toward that end.—Now in regard to Simplicity and flat covers. The very reason why you like the Simplicity covers makes them very objectionable to 99 out of every 100 bee-keepers in the United States. They do not want combs built up in this extra space; they want it built in sections or extracting-supers. Flat covers prevent any thing of this kind, and render it impossible for the combs to be built anywhere in places not designed for it by the bee-keeper.—A short time ago Edward R. Newcomb, the one who built your extractor, asked if we would like to see a photograph of it before he sent it. We requested him to send on a picture; and we now have the pleasure of presenting a view of it to our readers. We are not quite sure that your logic of decrease in centrifugal force is correct. At the same speed of revolution, the longer the radius the greater the centrifugal force. The graduated crank on the new Stanley, and the brake to stop the motion, is no doubt an

improvement. We shall be glad to hear from you further concerning it. Yes, we should be very glad to make you a call at some time. Possibly we may get around to do so.

WHICH IS THE CHEAPEST WAY TO RIPEN GREEN HONEY?

APHIDES, SWARMING, ETC.

On page 413 Mr. Robbins tells of getting about "the thickest, richest honey" he had by putting very thin and rank honey, just extracted from unsealed combs, in lard-cans, and stone jars covered with cloth, and setting where the "sun would pour in on it through a window," and leaving it there to cook. How long he left it cooking, he does not say. Doolittle says in the appendix to the A B C (48), that 90° is the requisite temperature, and three weeks the necessary time in which to thoroughly ripen honey. Now, the point I am aiming at is this: If one has no honey-house, and possibly no convenient room at the time in which to set his open cans, why will not the sun do this work for him outdoors, just as well as in a dark room, as Doolittle advises, or through the window, as above recommended? Does the sunshine ever become *too* hot, so that the color or flavor would be injured, or is it because moving back and forth would be too troublesome, that this method has never been mentioned in the journals? Situated as I am, it would be my cheapest plan to ripen honey, unless our temperature in this latitude indoors in summer is sufficiently high to ripen it *any way*, say placed in any closed room or out-house. At this writing we have a hot dry spell, with the mercury at 88° in the shade, with free-air circulation. In a shut-up room, where the sun falls upon the roof and walls, it is fully 95°. So far I have had success. My honey is always thick and fine by fall, and it is ripened both these ways; that is to say, when the sun shines I usually set the cans (five and ten gallon tin cans), where the sun will pour on them all day in the yard, keeping them in a closed room at night and during bad weather.

This spring our April and May flow was ruined by the March freeze, and honey has been coming in only about enough to enable brood-rearing to go on. Wishing to take some off two weeks since, I extracted five gallons of this unsealed honey that would "spill out" when combs were inverted. Some of it was put into Mason quart jars, with cloth tied on; the rest in a five-gallon tin can. That in the Mason jars is now thick and rich, while the larger quantity in the larger vessel is thickening much more slowly. A solar outdoor heat, considerably above a hundred degrees, fell on it two weeks. Would the same result have occurred if it had been kept indoors in the dark at 90° or 88°? Will not our average temperature in this latitude in summer ripen honey any way, if kept in open cans in a closed room?

Losing our spring crop entirely, it looked as if no surplus would come till fall; but the late drouth has brought honey-dew. Black-jack oaks are covered with it, and bees are storing a light-colored honey of good body, which they seal at once. They are just "roaring" all day, and hives grow heavier daily. This honey, some 75 lbs. of which I have just taken, seems to need no artificial ripening, that not sealed not shaking out when the comb is jarred. It evidently comes from aphides; is rather tasteless, but of better color and body than such

honey is described as having. Though they have given no surplus during the spring season, I never knew bees to multiply so rapidly. Swarming has been rampant all of May, and continues yet to some extent. In this connection I find that no number of crates of sections will stop swarming. "More room" of this kind will not answer. Invariably, also, "doubling up" and putting to-day's swarm where yesterday's came from, only delays matters long enough to enable cells to be gotten under way. Uppur stories of empty combs or foundation will check and often stop swarming, with me. During this phenomenal year every thing has "gone by contraries," and the busybodies have caught the infection; they have clustered higher, swarmed oftener, made less honey, and "played more pranks" than I ever knew they were capable of.

Pontotoc, Miss., June 5.

C. P. COFFIN.

Friend C., your plan of ripening thin honey I think is a rational one—letting the sun do it. The problem has been to exclude dust and rain, and at the same time get all the heat possible from the sun. I feel pretty certain that some ventilation through this, under the hotter part of the roof, would also hasten the ripening.

DO THE BEES MAKE HONEY, OR DO THEY ONLY GATHER IT?

IN OTHER WORDS, DO THEY ADD TO, TAKE FROM, OR CHANGE OVER NECTAR AS THEY GET IT FROM THE FLOWERS?

Dear Sir:—Is there any chemical change made in "sweet" from the time it is gathered by the bee until deposited in the *cell*?

A minister here claims that there is a change made by the bee; but as each kind of flower produces its peculiar kind of honey, when gathered by the bees, it seems strange to me that the bee in her "chemical manipulations" should *countenance* any such difference.

D. A. ROTHROCK.

Brighton, Ill., June 17.

Friend R., I think we may safely say that there is practically no difference or no change. There are some scientists and professors who insist that the bees do change the nectar in carrying it from the flowers to the hives, enough so it can be detected by the chemist. In order to get unfinished sections filled up at the end of the season we have fed to the bees different kinds of honey; but after being sealed up in the comb, it was exactly the same honey to all appearances. By accident we scorched one lot a little, and hoped that the bees in their manipulation might remove the slightly burnt taste. They did not, however, change it a particle.—Again, we once had a lot of honey that candied so readily we could scarcely keep it in liquid form at all. We melted it, added some water, and fed it to the bees. They evaporated out the water added, placed it in their combs and sealed it up, but it candied after being sealed up in the combs just as it did before we fed it to them, and I have never been able to detect that they improved poor honey in any way, neither have I been able to detect that any injury was done; or, in fact, that any change perceptible to any of our senses was wrought by any of their manipulations.

J. F. MCINTYRE.

ONE OF CALIFORNIA'S BEE-KEEPERS.

CALIFORNIA, that wonderful State bordering on the Pacific coast, where fortunes are made and unmade in a day, as it were, is not only one of the most favored sections in the world for fruit-growing, but it is hardly less remarkable as a great bee-country. Instead of furnishing localities that will support only 75 or 100 colonies, as many as 500 are kept in a single location. Bee-keeping in California, like that on the island of Cuba, is carried on on an immense scale; and we hope in our future issues to give more importance to this land of the setting sun. There are many extensive and distinguished bee-keepers in California. Some of the most successful ones are those who will not write for the public. There are others who are no less successful, but are able and willing to impart their knowledge to the bee-keeping world. Among this number is J. F. McIntyre, of Fillmore, Cal., who is not only an extensive bee-keeper himself, but has been associated with one of the oldest and best bee-keepers, Mr. R. Wilkin, for several years. For the present we take pleasure in introducing to you—

J. F. MCINTYRE.

Our friend was born Nov. 1, 1857, in Ontario, Can., eight miles from Brantford, where the last International Bee-keepers' Convention was held. Like many other sterling sons of toil he was raised on a farm, going to school in winter and helping to do the farmwork in summer. He was the oldest son in a family of three sons and three daughters. He was of an investigating turn of mind, and liked gardening; but

farming he detested. His father did not keep bees, but his neighbors did. Interested and charmed by what he saw of them, at the age of fifteen, with a capital of \$12.00, he made a start, \$7.00 of which he invested in a colony of bees. Later he saw advertised the bee-books of Quinby and Langstroth. The former he purchased, because that explained the *mysteries*, and very soon he constructed a movable-comb hive—the first one he ever saw. He afterward came in possession of Cook's Manual and the A B C, and subscribed for GLEANINGS and the *American Bee Journal*. He then bought a honey-extractor. With this he took, on an average, 150 lbs. of honey per colony from his apiary. As has happened to many other growing and successful bee-keepers, it set the neighbors wild. They all wanted to embark in the business. So many, in fact, went into it that it ruined his location.

Some articles which he saw in GLEANINGS and in the *American Bee Journal*, particularly some from E. Gallup, caused him to make up his mind that California was the place for a man who desired to make the culture of bees a *specialty*; and on the 7th of December, 1881, he bade good-by to his relatives and friends, and started for the land of gold and honey, but not, he says, without some regret on his part as he looked back and saw his mother standing in the door, with her handkerchief to her eyes. He reached Los Angeles, and was just in time to attend a session of a bee-keepers' convention there. Here he met a large number of old pioneer bee-keepers, who, he says, running over with hospitality, made him an honorary member of the association. He had been informed that Mr. Gallup wished to sell an apiary of 70 colonies in Ventura, Cal. This, with another apiary of 40 colonies, he purchased. He built a small house on government land, and for two seasons he kept "bachelor's hall." The first season, he says, was not a very good one, but he made nearly \$800. In the meantime he formed the acquaintance of R. Wilkin, who, the next year, desired him to work for him for two months. Now, Mr. Wilkin had a daughter, Miss Hattie, who, naturally enough, was a bee-keeper herself. It is not necessary to tell the rest: enough to say, that, following in the wake of many another bee-keeper, he found a helpmeet among the bees. In 1886, Mr. McIntyre, and his wife to help, took 42,000 lbs. from 240 colonies, the proceeds of which were sold for \$2000 cash. Two years later Mr. Wilkin sold 200 colonies in Sespe Apiary to Mr. L. E. Mercer, and moved the rest to his home apiary in Ventura, leaving his old location to his son-in-law. He bought up bees in the vicinity, and made it his home apiary. He had 150 colonies on the government claim, three miles distant, for an out-apiary, which was run during the seasons of 1888 and '9 by one of Mr. Heddon's apprentices, Mr. R. A. Holley, who has since bought it. Mr. McIntyre has now 500 colonies on the old Wilkin place, on Sespe Creek. He says it is all his location will stand. It seems remarkable that any location in the United States can stand that much. From this we get some

idea of the vast nectar resources of some of the California locations. Mr. McIntyre does all the work with the bees himself, with the exception of a man in the honey-house, to extract. Mrs. McIntyre does not now find time to work in the apiary, her time being taken up with the three little girls—Cora, Myrtle, and Lillie.

Mr. McIntyre has the honor of being the first-appointed legal foul-brood inspector in the county. In October, 1884, invested with proper authority, he cleared the county of about 300 diseased colonies. Two whole apiaries were found rotten with the disease. Both of these apiaries were burned. The county is now said to be almost free from the disease.

Mr. McIntyre does not devote his time wholly to bees, as he has a taste for raising things, such as oranges, etc. He has now 200 yards of seed-beds engaged for next spring's delivery, at \$2.50 per square yard.

E. R.

In the A B C book will be found a picture of friend McIntyre's home, the Sespe Apiary. The title of the picture is "Wilkin's Hexagonal Apiary." Since the picture was made, however, things have changed very materially about the Sespe Apiary. After my visit there in December, 1888, I gave a description. Friend M. has changed somewhat the order of the hives, preferring to have a passageway for a cart or wheelbarrow through the apiary, and at the same time leave another passageway for the bees to take their flight, the entrances to the hives being all turned into this lane, or avenue. As this matter has recently been up, we shall not need to go over it here. The artist has not done justice to the mountains in the background. What artist ever did, in fact? Even a photograph seems but a poor picture of the reality. During my brief visit at the Sespe Apiary, I remember many things that were wonderful to my untutored eyes. In front of the apiary, not shown in the picture, is the bed of a mountain torrent, and almost right before the house is a big rock that came down the river-bed one night by a freshet. This rock is pretty nearly as large as a meeting-house. It was on the mountains opposite, where I saw some little black pigs grazing. Upon looking closer, however, I discovered that the "little black pigs" had horns like cows; and then I was told that they were cows. Just back of the apiary the ground was so steep that it made me blow and puff to climb up where an irrigating canal was cut into the side of the mountain. As I stopped to take breath, not only tired but dizzy from looking down at such a height, I was startled to find one of the little girls (Myrtle I think it was) right at my heels, chatting with perfect unconcern. She had not only climbed fully as fast as we did, but she lugged a good-sized "dollie" besides. I uttered an exclamation of alarm, and was going to catch her before she tumbled down the mountain. Her father remarked, however, that there was no danger whatever—she was a child of the mountains, and trod with safety and unconcern where I almost shook with fear. And then the beautiful, spark-

ing, and bubbling water, rushing fast over its white bed of pebbles and crumbled granite! Some people might tire of seeing these irrigating canals, but I think I never should. May God's blessing rest upon you and your wife and little ones, friend M., in your far-away home amid the hills.

THE HONEY PROSPECT.

PROF. COOK TELLS US THE HONEY IS SLOW IN COMING IN.

Mr. Editor:—The honey outlook for 1890 is not very encouraging at the present time. The bees worked very lively on soft maple, and got quite an amount of honey, considering the strength of the colonies at that time. During hard-maple and fruit bloom the weather was so wet and cold that the honey product from this source was very light—just enough to cross-fertilize the blossoms, but not enough to essentially affect the bees. Right here I saw a nice demonstration of the value of bees. I know some cherry-trees that blossomed early, and before the bees could get out at all. The weather was cold and wet; the blossoms had withered, and the pollen and nectar were gone. Those cherry-trees have set almost no fruit, while neighboring trees and other kinds that blossomed a little later are bearing a fair crop. Few horticulturists realize how much they owe to the services of the bees.

The locusts have been in full bloom for over two weeks, and also the clovers and raspberries; yet, because of some peculiarity of weather, the nectar is almost wanting. Except for feeding, I think we should have lost heavily. Even now, though the bees seem to visit the clover and raspberries, they seem to be storing very little. There is something in this matter of nectar secretion that is quite puzzling. One would suppose that warm damp weather, just such as we have been having, would surely give an abundant harvest, but the truth is, the flowers seem stingy and selfish, affording just enough to attract the bees, that the flowers may be all right, but not enough to substantially benefit the poor laborers. We see that doling out in meager sums for service is not confined to human capitalists. I have taken my class to the apiary for years at this season, and this is the first time that I have had to delay, as the bees in enforced idleness are too cross to make it desirable to work with them when my class are all inexperienced.

GOLDSMITH BEETLE.

Mr. B. S. Brumley, of East Dayton, Mich., asks about a beautiful large beetle that he sends. It is known as the "goldsmith beetle," *Cotalpa lanigera*. In size, form, and habits, it is very much like the May beetle, or June beetle, often called May or June bug. This, however, is much handsomer. It is golden yellow, and often shines like gold. It is not often very common in Michigan; but this year seems an exception. About the 20th of May I was in a field prepared for corn near Howell, Michigan, where the soil seemed full of these grubs. I could have collected thousands in a few minutes. These beetles come forth in May or June, and, after pairing, lay their eggs on grass or other growing vegetation. The grubs are white, and feed on roots just as the "white grub"—larva of the May beetle—does. It feeds for three years, I supposed, as

does the white grub; but those I got at Howell must have been either four or else but two years in developing; for three years ago there was no crop on the field at egg-laying time, only young corn. The remedy for these as for the white grub would be to turn in hogs. They would eat the grubs, and thus convert the grass indirectly into pork.

SPRUCE-TREE PLANT LICE.

I have received some spruce twigs sent by J. H. Hill, Venice, Fla. The dried-up, broken aphides, are beyond identification. I presume they are the common spruce-plant lice, *Lachnus abietis*. This louse works on spruce-trees all over the United States, and here at the college it often secretes much and quite delicious nectar. It is closely related to the larch-plant louse, *Lachnus laricis*, which has not infrequently given us not a little most excellent honey. I have been able often to sample this latter right from the larch leaves, so abundant was it, and I can pronounce it A No. 1. I think it would sell equal to clover. Last season we got quite a little of the nectar from the spruce, and it was fine. In most cases, I think, honey-dew from aphides is fine, and excellent for honey. I wish we could say as much of that from bark-lice—*Coccidae*—but we can not. That is always rank, dark, and unwholesome. It is good to sell for manufacturing purposes only. A. J. COOK.

Agricultural College, Mich., June 19.

Why, friend C., do you mean to say that the white grub that bothers our crops and feeds on the roots of grass really lives three years? In plowing up clover sod around the windmill, there were such numbers of these white grubs that it called forth exclamations from the workmen. The neighbors' hens discovered what was going on, however, and they have been following the plows and cultivators ever since the ground was worked. There seem to be plenty of them left yet; but if they are going to live three years or longer, I do not know but I shall get discouraged before we get through; but may be the chickens will not, even if I do. By the way, I have mentioned one of the good things in regard to neighbors' chickens. Now, don't any of you ever say again that there is not a redeeming point to every drawback.

THE HOFFMAN FRAME DISCUSSED.

ITS DISADVANTAGES SET FORTH.

Mr. Root:—You ask for the pros and cons on the Hoffman frame. You are, I see, getting the "pros" without the "cons." Is not that the trouble with our writers on bee-lore? They give the good, and, to a large extent, leave out the bad. Now, Mr. Editor, I do not wish to be hard with the advocates of the Hoffman, or self-spacing frame; but not a single one so far gives both the good and the bad. I hope to be able to do both, and let you and your many readers judge for yourselves. I had about 1000 of what we call here the Georgia frames. The only difference in the Hoffman and Georgia is that the former frame has both top and end bar to close, while the latter has only a wide-end top bar.

Just here is an appropriate place to start my list of objections. In closing up, we kill more or less bees; the projecting ends are clumsy to handle—must

be pried apart with a knife; will snap, and get the smart hybrids afool of you in short order, in the way of taking cappings off the combs; will cause combs to pull out of frames while being raised from the board; they also will cause the combs to break out while being extracted, especially if it is necessary to turn a little fast; they will hang on the wire in putting in and taking out of extractor for any thing like fast manipulation; must be used in a wide hive, which will of necessity cost more, not to say any thing about the extra dummies and division-boards which are to be put away when not in use; then the frames will cost 50 cts. per 100 more than the Simplicity frame. In a word, I would say a bee-keeper who values his time must see the great difference in handling and storing away his frames. An 8-frame Simplicity body will hold 13 Simplicity frames, while 8 Hoffman frames will fill it; hence you see the difference in storage room, especially for surplus combs.

Now for the good: For shipping, the Hoffman frames are good; also for handling of full hives about the yard. They insure straight combs for the novice. One or two more minor good things, and you are done. Our bees to date are poor—not more than 5 per cent have cast swarms as yet. The May bloom was very bitter; but cool nights, followed by windy days, have been disastrous to the honey interests. I believe there has hardly been a day since the 1st of April when we have not had more or less wind. It is high at this moment. We like your Home department, also your Tobacco Column. Pineville, N. C., June 5. A. L. BEACH.

Friend B., we want the cons as well as the pros. We are glad you have stated the objections as thoroughly as you have; but it seems there are a good many in the Mohawk Valley, who like the Hoffman frame. Read the following testimonies:

HOW TO HANDLE IT.

Why rack our brains trying to invent something new, when we have something already in use much better adapted to the purpose than a new invention whose chief merit is newness and novelty? How many surplus arrangements, for instance, have we? and how much better is one than another in the same locality when we come to final results? My experience is about the same number of pounds of honey from each pattern in use, under the same conditions. The advantages of one over another may be counteracted by some point of its competitor. While such a long list of implements looks well in a price list, is it of any advantage to the manufacturer or consumer? I think if we would try harder to reduce the number of our appliances, and learn to use the best now in use to the best advantage, we might do something toward correcting what seems to me a growing folly.

Friend Beebe has covered the ground pretty well in his description of the merits of the Hoffman frame, and I can fully indorse all he says about it, and would like to call your attention again to one or two of these points, which I fear you overlook in your proposed modification of the frame you offer. I would say that I have tried this form, and have seen it in use, besides my short trial. You advise using tin rabbets. I have used tin and wood side by side, and decidedly prefer the plain wood rabbets with the Hoffman frame. This modification of yours admits the bees to the rabbet, and they will deposit enough propolis between the ends of

the top-bars, after being in use a short time, to seriously impair the convenience of the manipulations of the frame, which are the principal

ADVANTAGES IN USING IT.

It is not, on first opening, as perfectly movable as your metal-cornered frame; but after you have started the first frame, and drawn it from the hive, you can easily separate the remaining frames in any place (one of your five-cent screwdrivers makes a handy tool for this purpose), and shove any number of frames to the side of the hive without crushing a bee, and handle any frame you wish, without disturbing the remaining frames; and when you slide this last frame back to its place in the hive, you push the bees out of the way by sliding it down against its neighbor. It works a little more convenient to save, say, $\frac{1}{4}$ inch space on one side of the frames, which you can close with a small piece of wood at the corners if you wish; but I consider this last of small account, as I use the frame in hives with no space at all beside the frame.

I first saw this frame extensively used in the apiary of J. H. Nellis, of Canajoharie, N. Y.; and the writer, accompanied by the proprietor and his assistants, Mr. T. O. Peet, inventor of the Peet cage, and Mr. Silas M. Locke, examined a few hives of fine Italian bees containing imported queens. My companions expressed their satisfaction freely regarding the Peet cage and the Hoffman frame. This was several years before the Peet cage acquired a world-wide reputation. I have never forgotten the pleasure afforded me by this brief visit, and time has not effaced the impressions then received. I think that some of the above-mentioned gentlemen might, if they chose, furnish us with something worth hearing—perhaps something new on the subject.

ADIN STONE.

Vienna, N. Y., June 2, 1890.

Yes, friend S., we often try to rack our brains to invent something new, when there is something already in use which accomplishes the desired end a great deal better. Nowadays it is very difficult to invent something in apiculture which has not previously been thought out, described, and illustrated by some one years ago.

THE INVENTOR OF IT A SUCCESSFUL BEE-KEEPER.

Much has been said lately in reference to frames and brace-combs. I think every practical bee-keeper can tell you that more or less brood-combs will be built, no matter what frame you adopt or how small you contract the space between the top of the frame and the honey-board or surplus boxes. However, we know there is a great difference in this, in the use of different styles of frames. I remember the old American frame, or King frame, that had almost a closed top-bar, there being only a few openings made, by cutting away a part immediately over the brood-nest, to allow the bees to go up into the boxes. There were never any brace-combs built. Mr. Hoffman, the inventor of the Hoffman frame, is one of the most successful bee-keepers in this country, and his practical working led him by necessity (necessity is the mother of invention) to construct a frame that was a perfect separator, and one that could be handled rapidly. I was glad to see the illustration of this frame in May GLEANINGS, and the testimony of friends Beebe and Stone in regard to it; and I want to add my testimony to theirs, and I think we could muster a host of bee-keepers in the Mohawk Valley who

have used this frame, and are now using it, and could not be induced to use any other. There is friend J. H. Nellis, who used to stand at the head of the fraternity as a practical bee-keeper. He has used the H. frame for years, and says there are none like it. Of course, its cost is against it; but the large bee-keeper will tell you it pays in the end, simply by the economy of labor, and that is a big item in these days of hustling and rapidity of business.

Another point we might consider against it: If there is anything in the reversible idea, this frame, as constructed at present, can not be reversed, and this reminds me that I should like to hear the views of a man like Julius Hoffman on this subject of reversing frames. If there is anything in it, he has found it out, you may depend; and no doubt his ingenious brain has adjusted his frame to be reversed. I have an idea myself how it might be done, but I won't give it out till I have demonstrated it successfully.

THEO. O. PEET.

Arlington, N. J., May 31, 1890.

Yes, friend P., we are very glad that we have the testimony of Julius Hoffman himself. He writes as follows:

WHAT THE INVENTOR SAYS OF IT.

In reading Nos. 9, 10, and 11 of GLEANINGS I find that, in discussing "spaced frames," the frames I invented and used for about sixteen years have been brought to notice by some of our bee-keeping friends. But as the description and illustrations of the frame as I have them lack some important points I will make a few remarks about them.

One of the edges of the uprights, or ends of the frame, as far as they are close fitting, should be beveled off to a little less than $\frac{1}{8}$ inch, so as to meet the center of the square edge of the next frame, as in E, of the diagram. This will prevent the gluing and sticking together of the frames, also squeezing of the bees to a large extent, and allow faster working of them.

The corners of the top-bars of the frame at C should not be taken off more than just enough to allow for turning the frames easily in the rabbets, otherwise the bees will have too much of a chance to fill up the rabbets with propolis. For the same reason, I object to your modifications of the top-bars as the jutting points of them, as called by Ernest, are very important, in order to fill out the rabbets to keep them free from bee-glue. To use these frames on tin rabbets, as proposed by Ernest, would, according to my experience, be a very doubtful improvement. The frames would slide too easily on the rabbets; and carrying and moving the hives would soon convince him of it. The way I use them on wooden rabbets, the frames are just

glued fast enough to allow the moving of the hives without any preparatory fastening, unless the hives are only partly filled with frames. In this case I take a piece of burlap, or any cloth that I use for covering up the frames; roll it into a bunch, and stuff it behind the spacing-board.

The close-fitting part of the side-bars should extend at least 3 inches down from the top-bar. As a well-made frame lasts a good many years, their extra expense amounts to but very little, if they have any advantages over others.

JULIUS HOFFMAN.

Canajoharie, N. Y., June 15, 1890.

The points you make are well taken; but it does seem to us that the frame as you make it would be too expensive for the average bee-keeper to use. E, E, if we understand it correctly, are cross-sections of the end-bars, looking straight down. Beveling the end-bars would be rather expensive, and the rounding of the points, C, C, C, etc., would be another item of expense; and yet it is true, that a well-made frame will last a good many years; and the extra expense, of course, would be but little on each year of use, providing additional ease of manipulation is secured.

E. R.

WOODMAN, SPARE THE TREE.

SOMETHING ABOUT EMBELLISHING CHEAP SECTIONS.

"Is there any thing whereof it may be said, See, this is new? it hath been already of old time, which was before us."—ECCLES. 1: 10.

Bro. Root (please allow me the use of this salutatory phrase, as we are both children of the one Father, God). I have noticed a great deal of uneasiness expressed by writers for the bee-journals in regard to the great consumption of basswood for sections, etc., and the consequent decrease in honey from that source; but I was not so strongly impressed, nor did I realize any imminent danger from that source until brought to the realization of the fact by your statement that you alone had ordered two carloads of sections of Mr. Lewis. Now, add this to the great amount your and all other more or less extensive manufactories must turn out, and one can easily imagine the wholesale slaughter that is going on in the linden forests. We must also consider the alleged hair (?) mattress we find in hotels. At the present rate of destruction that has been inaugurated against the old linden, it will be only a question of time when a "chunk" of nice delicious linden honey in a beautiful basswood section will be "a thing of the past."

THE REMEDY.

Some have recommended planting basswood forests, which is wholesome advice when we are considering the welfare of coming generations, "because I shall leave it to a man that shall come after me;" but the remedy that should be sought should be one that would be beneficial to the present as well as future generations. I am now going to offer a solution to the problem; and if it is impracticable, or "has been up before," please consign this to the waste-basket right quick; but on the contrary, if it is likely to become a thing of beauty, and, consequently, a joy for ever, then the fraternity are as welcome to it as the flow of honey that God gives them from year to year. You see, people would scarcely tolerate a section made of dark

wood, such as elm or even pine; but my idea is to make them out of even such, then beautify or embellish by having labels, either of white paper printed plain or lithographed with several colors, and cut with the proper insets the same as an unfolded one-piece section, being printed on all sides with appropriate address, kind of honey, and any explanation deemed necessary for the improvement of the honey-trade. Now, when your sections are taken off and relieved of the accumulations of propolis, this gummied label could be wrapped around your dark wood, covering up all defects, making your dark section even more beautiful than the whitest basswood. All scratches, stains, and joints would thus be hidden; the producer would be sending his advertisement and other apicultural literature broadcast into every honey-consumer's home, besides saving this desirable honey-producing tree. I don't think, either, that a section made of cheap material that can be procured around any factory and thus labeled would cost any more than the present linden production; and even if it did, the preservation of the basswood would surely more than compensate.

J. H. MARKLEY.

Carbondale, Kan., June 16.

The same thing has been suggested many times. The only difficulty is the amount of labor required to put the paper on nicely. I do not believe it could be done profitably. I am inclined to think, too, that most kinds of paper would soil more easily than the basswood. You see, the paper must be exactly the width of the section, to have it look well. Folding the edges down over the edge of the section would be very nice, but this makes still more labor, and it is a hard matter to get it down nicely and have it stay. Have any of the readers of GLEANINGS ever put this into practice? The pasteboard boxes which we sell in large quantities to slip the section into come pretty near what you suggest, and it is not very expensive. We heartily agree with you in regard to the consequences of slaughtering the basswood. What else can we do?

SPACING BROOD-COMBS.

AN OPEN LETTER TO DR. C. C. MILLER.

"WHAT is the proper distance from center to center to space brood-combs—1½ inches?" asks Dr. Miller on page 416, June 1st GLEANINGS. He then goes on to tell us that, so far as he knows, this distance is all right, and concludes with "somewhere about 1½ inches from center to center is right; but I don't suppose it is exactly 1½. How can we find out what it is?" when he next adds, "Upon that depends our spacing and the width of our hives." It is hardly necessary for me to say that I read this article of Dr. Miller's with more than common interest, although I read all of his articles with interest beyond what I do those of most of the writers, for he has a peculiar and fascinating way of getting at what he wants, without committing himself very positively as to any thing; hence we must read with interest to find out where he stands. Friend Root's foot-notes were right to the point, for I really feared that we might yet be able to place our combs so close together, if some one carried out the doctor's reasoning a little further, that we

should need no bees at all, but could fill out our hives solid with combs of brood with only a few bees and the queen around the outside, which would so cheapen honey that the most of us would have to go out of the business, leaving the doctor and Bro. Heddon in possession of the field alone.

Well, now, doctor, I will tell you just what is the right distance from center to center to space brood-combs. It is *exactly* $1\frac{1}{2}$ inches; no more and no less, where all worker combs are used, and $1\frac{1}{8}$ inches where drone comb is used. You said you did not know why $1\frac{1}{8}$ is better than $1\frac{1}{4}$ or $1\frac{1}{2}$, but I will tell you *why* $1\frac{1}{8}$ is the right distance, and how I know it to be so. You know, doctor, that I am great for following nature, even if Bro. Root does say that in queen-rearing I am the furthest from nature that any one can conceive of. Nature told me that $1\frac{1}{2}$ inches is right when I made my first hives, more than 20 years ago. At that time I could not find in any of the books on bees that I then had, how far apart the frames should be placed; so, in order to ascertain, I went into the loft of the barn where were stored all the old box hives from father's old apiary, to the number of some 30 or more, and, upon measuring the inside of the tops of the hives where the combs had been cut from, I found that all of the central combs were just $1\frac{1}{2}$ inches apart, while some of the combs near the sides of the hive were from $1\frac{1}{8}$ to 2 inches apart; those being the furthest apart where the combs run in the hive so the last one comes in the corner. Since then, whenever I have come across a box hive where the bees were out of it, I have measured the distance of the combs apart where they were attached to the top of the hive, and I have found them invariably the same, to an exactness approaching the thirty-second of an inch. Is it to be supposed that the bees do not know what is right in this matter, when they have to furnish food, fuel, and the whole business? In order to keep up the necessary warmth for brood-rearing in early spring, the bees form a living wall around the brood, thus keeping the heat from escaping the cluster; and to do this it takes the depth or thickness of two or three bees all the way around, as I have often ascertained by tipping up the hives at that time of year. Did you never tip up a hive carefully some frosty morning in April, doctor, and closely examine the bees between the ranges of combs? If you never have, it will be an interesting thing to you, if you are any thing like me. How nicely they are packed, all with their abdomens pointing away from the center of the cluster! This is the hive proper; and inside these bees, brood-rearing is going on nicely, while some unlucky bee on the outside is so cold that it can hardly walk or move. But, enough on this point, as I wish to look at some other of the doctor's calculations.

He says, "If I am not mistaken, worker comb, when first made, is $\frac{3}{8}$ thick." In this he is very nearly if not quite right, for that is as I find it to be; but when he comes to figure this same $\frac{3}{8}$ in his calculation of distances, even did the combs never grow any thicker, he is making a great mistake, for there is one factor which he does not take into consideration, which is, the capping of the brood. When the brood is capped in this $\frac{3}{8}$ comb, Dr. M. will find that, from outside of cappings to the opposite outside, is exactly one inch; and where the combs are so old that they are one inch thick, with

no brood in them, they will be $1\frac{1}{8}$ thick after the brood is capped. Dr. M. will see that this does away with all the calculations in his article, and leaves him at "open sea" full more than he was when he commenced. I had measured worker brood many times; but to be sure I was right I have just come from measuring many combs, and can find none—no, not one—with capped brood, that measures less than one inch, although I have measured some having brood in for the first time. The way I measured was as follows: I took a small steel wire, which had been painted black, and filed one end to a sharp point; then beginning at $\frac{3}{8}$ I made a nice rule by marking $\frac{3}{8}$ of an inch on it up to $1\frac{1}{2}$ inches. I now went to the hives, took out combs from different ones, and pushed this wire through the sealed brood till the point began to make an impression on the sealing on the opposite side, when the ruled side gave me the depth, and in no case was it less than one inch; while the older combs were all the way from that up to $1\frac{1}{2}$.

Another thing: As the bees rambled by on the comb alongside of this rule, I found that they stood on the comb so that they were all the way from $\frac{3}{8}$ to $\frac{1}{2}$ inch high; and as I claim that the combs should be far enough apart so that the bees can stand back to back if they wish to, this would say that the combs should never be nearer together than $1\frac{1}{2}$ inches. I might go on and tell how I had tried friend Pond's close spacing, and various other experiments which I have made, which were not satisfactory, till I now space all combs for worker brood $1\frac{1}{8}$ inches apart; but it would make this article too long, so I will say adieu where I am.

Borodino, N. Y., June 19.

G. M. DOOLITTLE.

I have always told correspondents in GLEANINGS that $1\frac{1}{8}$ was the proper spacing; but when I read your article through I was up in arms, ready to take issue with you on the thickness of capped brood. But before replying to you I thought I would go out into the apiary and see how *our* bees did. I first went to one of the kegs containing one-inch wire nails; selected two or three that were exactly that length by a rule. I then measured old and new brood comb, and into each I pushed the nail up to its head. I found in every case that the point of the nail stuck out $\frac{1}{8}$ inch. These combs were some that we had stored away in the house-*apiary*. Some had been used seven or eight years, and some only two years. Some was natural comb, but the most was built from foundation. We (Mr. Spafford and I) then went out into the apiary, selected at random combs of sealed brood, pushed the wire nail through so the head was just level with the capping. The point of the nail just pierced the capping on the other side. We measured old and new combs of sealed brood, and found them all exactly an *inch thick*. I had expected to find some thicker, but did not. Well, now, if capped brood is as a *rule* one inch thick from capping to capping, on $1\frac{1}{8}$ spacing, we shall have just $\frac{3}{8}$ inch between the surfaces of capped brood. We usually consider that $\frac{3}{8}$ is a large bee-space, $\frac{1}{8}$ small, and $\frac{5}{16}$ just right. Now, if I measure bees rightly I can not make them in our apiary *average* over $\frac{3}{16}$ high on *sealed* brood. On *unsealed* brood they stand a little lower because their feet extend a little into the cells.

Unsealed brood is ordinarily only $\frac{1}{4}$ inch thick and requires more care, attention, and warmth than does sealed brood. The average unsealed brood is $\frac{1}{4}$ in. thick. Therefore, in $1\frac{1}{2}$ -inch spacing there is $\frac{1}{2}$ inch between the surfaces, and plenty of room for the bees to back in and out of the cells. After it is sealed, $\frac{3}{8}$ in. is enough, I think. Now, while I would admit the facts about the thickness of comb and brood, I would not quite agree with the conclusions you draw therefrom; $1\frac{1}{2}$ spacing I should still think is enough. Some of the bee-keepers in New York, using standing frames and fixed distances, and having had their frames spaced $1\frac{1}{2}$ inches apart, have now abandoned that spacing, and have adopted, instead, at considerable expense, $1\frac{1}{8}$ spacing. D. A. Jones argues for $1\frac{1}{8}$ and $1\frac{1}{4}$ inch spacing. Frank Cheshire says scant $1\frac{1}{8}$ is correct, because it results in the exclusion of drone brood; Langstroth, years ago, allowed that distance— $1\frac{1}{8}$. Now, I never heard that these authorities or their large following could not rear as much brood as those who used wider spacing. In our apiary we used to use nine frames, and this gave us about $1\frac{1}{2}$ -inch spacing. The result was, that we had crooked and bulged combs. Latterly we have been using $1\frac{1}{8}$, and like it better. It is true, as you say, that the combs in box hives are $1\frac{1}{2}$ inches apart in the center. A number of correspondents have reported this to be true; but because Nature does so, is it any reason why the bee-keeper who wishes to properly control the hive should adopt this spacing? Nature sets out trees promiscuously, scattered here and there; but the fruit-grower likes to have his trees in rows; and so do all of us who like to have shade-trees, and wish to adorn our homes. While we must pay some regard to nature and her methods, yet there are improvements that necessitate changes. Nature spaces combs for both winter and summer, and for drone and worker brood. Is it not desirable to have these things under control? In winter we want wide spacing; and when honey is coming in, I believe that closer spacing helps very materially to force the bees into supers, although I may be mistaken. In the sections we want combs over 2 inches apart from center to center. Now, friend D., it may seem a little like presumption in me to reply to you before Dr. Miller has had a chance. The fact is, I have studied this matter a good deal; and after a good deal of investigation I have formed some conclusions. I will not say positively that $1\frac{1}{2}$ -inch spacing is right; but there is an awful big following who are using it, get big crops of honey, and lots of brood. I am aware, also, that there are perhaps as many using $1\frac{1}{8}$ -in. spacing. The majority of our "Question-Box" respondents vote for $1\frac{1}{2}$ inch, but it seems to be because they happened to use this distance at first, and have continued it since. Perhaps Dr. Miller will now be better able to decide which is right— $1\frac{1}{2}$ or $1\frac{1}{8}$.

ERNEST.

Ernest has covered the whole ground so thoroughly that I hardly need add anything. I will call attention, however, to the fact that most of the remarks above

take it for granted that the combs are pretty accurately spaced; whereas, in real practice the combs are never accurately spaced. The only way in which accurate spacing can be preserved, that I know of, is to have frames at fixed distances, and always put them into the hive in the same order. Then you have it. If, however, they are swapped about, the distances are being continually varied, and, as a consequence, the bees do more or less tearing down and building up every time the frames to the hives are removed; therefore I should say that, in the light of the facts given by friend Doolittle, we certainly need a little more than $1\frac{1}{2}$ inch.

WORKING ON ALFALFA.

WONDERFUL RESOURCES OF THE LOCALITY OF
GARDEN CITY, KANSAS.

I ARRIVED here the 25th of April, with 60 colonies of bees, for the purpose of securing honey from the great alfalfa fields. The bees did moderately well from the prairie blossoms before alfalfa came in, which was perhaps two weeks ago. They are now becoming strong, and some have swarmed. I think most of the honey comes now from alfalfa, although I find the bees thicker on the prairie flowers. If there should be plenty left for seed of the first crop, I shall probably get a good yield from it. They get seed generally from the second, although some try for two seed crops. There seems to be little honey in the first blossoms. The only serious obstacle in the way of success with bees here is the wind, which is often strong, and comes pretty near being constant. I believe there is a great future in this country for the farmer and horticulturist. I never saw such healthy-looking fruit-trees before. They have the conditions of Cole's "New Agriculture" to perfection here—an underflow from 4 to 15 ft. from the surface near the river, say two miles wide, and on higher land 60 ft. Also in some valleys back from the river it comes near the surface. It is inexhaustible. There are wells here four feet deep which can not be drawn dry. It is like dipping from the river, with a fall of seven feet to the mile. A way to irrigate, independently of the river and the dams, which may wash out, will readily suggest itself.

J. B. COLTON.

Garden City, Kan., June 16.

COVERS TO HIVES; SAGGING OF TOP-BARS, ETC.

DR. MILLER DEFENDS HIMSELF LIKE A MAN.

DON'T you think it's a little rough for you Roots to come at me as you've done on page 466, and the whole crowd of you to jump on to me? Well, let me take you one at a time. First, the old one. You think the Simplicity cover warmer than the flat cover. Yes, and so are the telescope ones I formerly used better and warmer than the Simplicity; but there's more simplicity about the flat cover than either of them, and on that account I prefer them. You must use a quilt of some kind with the Simplicity cover, and the most of the flat covers are all right with no quilt. It's the exception when a flat cover doesn't fit right, but I don't like the exceptions.

As to diagonal wires and tin bars preventing sag-

ging, do they? I have heretofore said I had no trouble with sagging; but since exactness of bee-space has been so much insisted on, I am troubled with what didn't trouble me before. All the sagging didn't trouble me as much heretofore as the tin bar would. But when you come to the matter of exactness, lay a dozen of your frames one on top of the other, and see if the top-bars are all exactly straight. How do the diagonals and bars "make an absolutely sure thing against sagging"? The tin bar simply ensures an exact distance between top and bottom bar, but that does not prevent both sagging. The diagonals insure that there shall be no more sagging than their length will allow. If the diagonals are drawn too tight, will not the top and bottom bars bow up? and if not drawn tight enough, then sagging follows. Theoretically, the whole thing depends on drawing the wires just tight enough, but possibly that may not be so difficult in practice as in theory.

Now for the young one.

That cleat. You know that the cleat is stiffer before that groove is cut out of it. The board must stay secure in the groove, and nails alone will allow a board, I think, to warp a little more. Still, no serious trouble comes from that when the cover is of a single straight board; but I have some made of two boards with a tin-trough arrangement to prevent leaking, and they have warped more. The principal difficulty comes, however, not from the boards warping, but winding. No cleat can prevent that. You say you never saw a cover of the Dovetailed hive that warped any. Neither did I see any of mine when no older than yours. I suppose you will say I ought to have painted my covers; to which I have no reply to make. Perhaps the trouble comes more from the hives being out of true than the cover, and you needn't throw up to me the squareness of your Dovetailed hives. Just as fast as my old hives become too rotten to use, I'm going to have Dovetails in their place. No, I don't put tin on my flat covers, but I did on my wider covers, and I'll mention an objection to the tin. It doesn't allow evaporation, and water stands on the inside of tinned covers in large drops, quite often, from the breath of the bees.

BEEES KILLING DRONES IN JUNE.

I never saw so much of it before. It can hardly come from scarcity of stores, for every shake of a comb brings a shower of thin honey. Perhaps it may be where a young queen is about to take the place of the old one. And now a question:

WHEN DOES THE SUPERSEDING QUEEN TAKE THE PLACE OF THE OLD ONE?

Or, rather, when is the old queen removed? Does the young queen generally kill her when she first hatches out, or is the old queen retained till the young one gets to laying? Economy would suggest the latter as the better course, and my observations, lately, have inclined me to the opinion that it may be a very common if not the usual course. Can you tell us how it is?

ARE BRACE-COMBS DESIRABLE?

Doolittle generally knows what he is talking about; but isn't there something different about his arrangements that makes the difference? I find that my bees go to work in the sections just as soon as any thing is to be put in them; and even when there is so little to store that they can only fill the bait, I have had them in the late years of

failure fill the bait and leave the other sections untouched. Surely, I don't need brace-combs.

Marengo, Ill., June 21.

C. C. MILLER.

Look here, doctor: the old telescope cover takes too much room, of course, for you and I who have out-apiaries, to load bees into wagons. Diagonal wires and tin bars do prevent the sagging, but they must be very nicely put in and adjusted. The tin bar must be used so long and no longer, and the diagonal wires must be just so tight and no tighter; and, since you mention it, I do remember that I almost always scolded when we fixed up a lot for our own apiary.—My impression has been that the old queen is rarely if ever killed by one of her own daughters. The only proof to the contrary that I can think of is that we do not often find two queens, mother and daughter, in the same hive. I do know, however, that there are two, a good many times, when we don't know it. Excuse me if this statement is a little contradictory. Now, doctor, do you mean to say that your bees always go to work in sections when they ought to be at work there? Don't you know some contrary colonies that cram the brood-nest and leave the sections untouched?

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 163.—*What width from center to center do you think it best to have brood-combs? Do you keep them the same distance the year round?*

1½ inches. 2. Yes.

Wisconsin. S. W.

E. FRANCE.

1. 1½ inches. 2. I do.

Illinois. N. W. C.

MRS. L. HARRISON.

1. 1½ inches. 2. Yes.

Illinois. N. W.

DADANT & SON.

1½ inches, and the same above as below, as I extract only, and am so often changing combs up and down. 2. I do.

California. S. W.

R. WILKIN.

I always have used 1½ inches, and see no good reason for changing. The bees build them thus when left to their "own sweet will." 2. Yes.

New York. C.

G. M. DOOLITTLE.

If I could have the combs always hang perfectly true, I would have them 1½ inches. 2. No. In the spring I crowd them as close as they will bear to be; in the summer, 1½ inches from center to center, and further apart still for winter.

Ohio. N. W.

A. B. MASON.

1½ inches is the distance we use them. I am not prepared to say it is the proper distance. 2. We do not change them, although we have the excellent authority of Mr. Manum for so doing. Unless well protected, my present limited experience is against narrow spacing for spring brood-rearing.

New York. C.

P. H. ELWOOD.

1. 1½ inches; 8 in a hive, 11½ inches wide inside.
2. Yes. I think it somewhat better to spread them a little wider apart in the winter, but not enough better to pay for the trouble.

Illinois. N. C.

J. A. GREEN.

Mine are 1½, but I don't really *know* whether that is best. 2. Yes. There might be some advantage in having them further apart in winter than in summer, but I don't believe it would pay for the trouble of changing.

Illinois. N.

C. C. MILLER.

I have my frames about 1½ inches from center to center, and do not have them fixed so as to be just so far apart. I have used those that were spaced, and did not like them. I can space with my eye to suit me best; a slight variation is not objectionable.

Michigan. C.

A. J. COOK.

1½ in winter, in order to allow more bees to cluster between the combs, which gives them a better opportunity to generate more heat between combs.
2. No. I think 1½ or 1¾ is about right when working for box honey, as I think bees will enter the boxes more readily when the combs are closely spaced.

Vermont. N. W.

A. E. MANUM.

1½ inches, but I am not particular that each frame is exactly spaced. With hanging frames, the eye gauges the distance. I have practiced taking out one frame during winter, and giving more space; but after several years' experience I can not see that the bees winter any better with the added space.

New York. E.

RAMBLER.

About 1½ inches; a little less rather than more. I say, *about*; perhaps it is not best to be too definite about the matter until we understand more of its importance. I suspect that, in the future, there will be more importance attached to the adjustment of the brood-frames than there has been in the past. 2. Yes.

Ohio. N. W.

H. R. BOARDMAN.

The best results are obtained when the frames are apart from center to center about 1½ inches, or a little less. It is not necessary to attach great importance to the one-sixteenth of an inch. 2. Careful and repeated tests have convinced me that no improvements are realized by spreading the frames during the winter months.

Ohio. S. W.

C. F. MUTH.

The room for difference of opinion here is but a small fraction of an inch. Between the widest and narrowest spaces that are used by good apiarists I do not think there is much to choose. One and a half inches is perhaps as good a distance as any. 2. When convenient I like to widen the space a little when fixing them for winter; but the matter is hardly important enough to justify breaking open all their sealing on purpose to widen the space.

Ohio. N. W.

E. E. HASTY.

1½ inches. A large per cent of my colonies are in the Gallup hive, inside dimensions 12×18×12½ inches high. In hiving young swarms we use 12 frames to the hive; space 1½ inches apart; but with old combs, and combs bulged a little, we run many with 11 to the hive, to facilitate matters in handling, rather than to keep all pared to the right

thickness. 2. We have practiced, to some extent, spreading the frames in fall, but have concluded that it does not pay for the trouble.

Wisconsin. S. W.

S. I. FREEBORN.

After trying many distances I allow 11½ inches for eight frames. 2. Yes, sir; and any system proposing to space the frames differently between winter and summer will get behind the times, for no such kind of manipulation can be afforded by the successful bee-keeper of to-day. That is what I think. By the way, it will be well enough to here mention that I am writing what I think, and not what some one else thinks. I respect other people's opinions when they differ from mine, and I believe I deserve some respect for writing my honest opinion, regardless of others.

Michigan. C.

JAMES HEDDON.

See answer to G. M. Doolittle on page 491.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

THOSE SERMONS; WHITE CHITTIES.

I am more interested in your sermons than I am in the bee business. I have, or keep, only a few bees. I subscribed for GLEANINGS on account of the bees, but now I read the sermons first, and they have become part of my spiritual life. May God bless you in your work of faith and labor of love. I want to tell you that we have *while* "Chitties" here; two per cent a month in advance every three months, and corn thirteen cents per bushel! The only difference I see between Munson's Chitties and ours is the color of the skin and amount of clothing.

THOMAS ADAMS.

Gaskill, Kan., Feb. 21.

Yes, friend A., there are white Chitties, I fear. Now, there is great need of a good Samaritan right in this line; and I do wish that somebody—lawyer, minister, banker, or political economist, would tell us how men of capital can help poor people in trouble, by loaning them money at a low rate of interest. If I am correct, these high rates of interest are always received where an investment is risky—so risky that the money-lender loses a great many times. He takes risks that an ordinary banker or moneyed man would not take at all, therefore he gets a rate of interest that will allow him to loan his money so that he can afford to lose one time out of three or four. It seems to be a sort of lottery business; and as his very life (that is, his financial life) depends on getting his money, he gets hard, unfeeling, and unscrupulous. The experiment has been tried to some extent, of giving money outright to those who were in need. Sometimes it works well, but too often it only encourages the one helped, to go into some new piece of extravagance or folly. Why can't this whole thing be managed in the spirit of love between the money-lender and the money-borrower? I feel sure there is something wrong on both sides, or there would not be that bitterness that exists between the two parties. Right in this same line we have the pawnbroker, who advances money to people who are in seeming distress.

It seems to me the pawnbroker might be and ought to be a very good Samaritan. But just think of the estimation in which he is held. His very name is a slur and a reproach. The world seems to think it is a disgrace to be seen going into such a place as a pawn-shop, and a still greater disgrace to keep such an establishment. It really seems that the world means to have us understand that anybody ought to be ashamed of himself who gets into such straits as to have to pawn his possessions. But, dear friends, how about the homeless and the friendless, the sick and the suffering, and the widows? Perhaps the world will say that it is everybody's business to stay where they are known, and to have friends, and that everybody who is fairly deserving does have friends who will stand between them and want in the time of need. This may be so; but the whole matter is a sad one to me. Let those who so severely censure the money-lenders remember that lending money is hard, severe work—work that wears and tears on the mind and body. It is easy to *lend*; but I tell you, my friends, it is hard to get your money *back*. We ought to know something about it, with all our book-keepers and clerks to look after the little dribs as well as the big ones; to look after the continual stream of losses that would break us down financially if we did not almost fight for our own. I have sometimes wondered whether the good friends did not think *we* were hard, cold, and unfeeling. If they do, please read over again the article on page 341, 1889. Now, dear friend A., do not, I beg of you, think this little sermon hard and unfeeling. It has been written with the kindest feelings toward erring humanity I ever had in my life. I do know that it is terribly hard to sell corn at 13 *cts.* a bushel. May God grant that the time may come when some of these very poor people we have been talking about shall have the opportunity of *buying* the corn, providing it *must* be sold at such an insignificant price.

AN ATTACHMENT FOR CATCHING GRASS FROM A LAWN-MOWER.

I send you a sketch of an apron for a lawn-mower, which I made last summer, and found it did very satisfactory work. It keeps the grass from falling on the ground, and so saves the necessity of raking it up; and while raking is not very pleasant work, it also takes time, and it leaves the lawn with a ragged appearance. It may be made as follows:

Get a piece of heavy steel wire, about six feet long, and two strips of pine, 1½ inch—one 18, and the other 20 inches long. Also two thinner strips the length of the knives on the mower. Lay the first two strips down on the edge, with the shorter one at the right hand, and then nail the thin strips down on top. Bend the wire, and fasten it on top of the framework, with either staples or small wire, leaving about 4 inches at each end for a hook. The wire should project further toward the left hand, as the knives throw the grass that way. The other side should not reach beyond the wheel, as it would be in the way of running close to trees or buildings. The hooks are made long, so that there may be a chance for fastening them, after passing around

the roller bearings, thus holding it firmly in place. The front ends of the runners should be rounded, so they will not catch in the grass. Fasten stout strings to the back of the runners, long enough to tie to the handles. Now cover over all with enameled cloth, with the enameled side up, and hem the edges under. Hook on to the machine, fasten securely, and tie the strings to the handles, so the back of the apron will just clear the ground, and it is ready for business. Unless the grass is quite tall it will run quite a while without being emptied; then it may be shoved off in a pile in a convenient place, and afterward gathered up. The weight of the extra load is scarcely noticeable, and I think any one who uses a lawn-mower will find it a saving, both in time and labor. I have not found it necessary to have a curtain around the sides, as but little will fly over unless it is very windy.

Farina, Ill., Apr. 25. D. M. ANDREWS.

FOUR-BANDED ITALIANS; WHERE THEY CAME FROM.

Friend Root:—In reply to your inquiry on page 378, May 15, 1890, I would say that, in the fall of 1882, I bought of G. M. Doolittle a select tested queen of the golden Italian strain, with which I was greatly pleased on account of the gentleness of worker progeny; but in the spring following I lost this queen by uniting a colony of black (German) bees with the Italians. Next spring I ordered from friend Doolittle another of his best select tested queens, and from this one I got my present strain of four-banded golden Italians. It is true, as friend Doolittle will tell you, that I have greatly improved them in that beautiful golden color, and I have established a strain of Italians producing uniform red drones, and at the same time I have tried to keep them up to his standard for gentleness and honey-gathering. How I have succeeded in my efforts in this direction, many of my patrons can testify. I don't claim them to be better honey-gatherers than the imported Italians, but that they are equal to them in this respect, and much more gentle to handle than any other bees I have ever tried; and as friend Doolittle said some time since in GLEANINGS, "If we can combine beauty with the other good qualities of the Italians, are we not a step in advance?" To get these bees up to the present standard I have devoted six or seven years; and for this labor I feel amply repaid, both in dollars and the satisfaction of knowing that, with the continued assistance of friend Doolittle, I have greatly improved the ordinary Italian bee.

L. C. HEARN.

Frenchville, W. Va., May 20, 1890.

ANOTHER PLAN OF HORIZONTAL WIRING.

I herewith give my way of wiring frames, which I have used for some years. You will notice that it is on the same principle of tension as the one given by E. D. Keeney, in May 15th GLEANINGS. I first stretch the wire four times across the frame through the end-bars, then draw tight, and fasten. I then take a piece of wire and wrap it once around the center of top wire, then around each one below in succession, holding with the other hand in such a way as to draw each toward the center, giving them all the tension they will bear.

Economy, Ind.

A. G. MENDENHALL.

I had studied out your plan, friend M., and was about to give it to the readers of GLEANINGS as a superior method when

Keeney's plan was presented to me, and I at once thought it was so superior that I would abandon my plan and give Keeney's instead. Superior in what point? Because the tension is on the four corners of the frame, and not in the end-bars, as in mine, or, rather, yours. As Keeney's takes no more wire it does not require to be pierced, and only four bent nails, together with the fact of tension being produced at the strongest points, decided me as to its superiority. I am glad to know you have used it some years with success, for it helps to prove that Keeney's plan must likewise be a success.

MELTING OLD COMBS WITH OLD POLLEN IN THEM, AND HOW TO DO IT.

Being an old subscriber, I take the liberty of asking a few questions. In cutting out old brood-combs for wax, is it best to save those half-full of pollen? Will the bees ever use the old pollen?

Williamson, N. Y.

FRANK ADAMS.

Yes, bees will, in the spring, use up the old pollen in the combs. You can melt up the old combs with pollen in them. We recommend, in the A B C of Bee Culture, putting old combs in a cheese-cloth bag, and then weighting the whole down under hot water. The clear wax will come to the surface of the water, and the refuse will remain in the bag. A very nice, easy way, is to put all such in the solar wax-extractor, and just let old Sol give you a nice clear cake of yellow wax, without "any bother" too.

ANOTHER POINT IN FAVOR OF HORIZONTAL WIRING.

You omitted one good point in the wiring of that frame mentioned on page 371. In cleaning top-bars of burr-combs this spring I got more than 10 lbs. of wax; but the trouble is, I have to work so slow or break wires. If for this and nothing more it would have been worth dollars to me to have known it before I wired 10,000 frames this spring.

Carrollton, O.

C. V. KINTNER.

Yes, we did omit to make that point. There has been so much trouble from cutting the wires on the perpendicular plan that some of the friends in ordering have asked to have the top-bar grooved to let the wires in. The horizontal wires, or the plan of wiring mentioned on page 371, would obviate this trouble.

FROM AUSTRALIA.

I am a bee-keeper—that is, if you count a man one who has 150 colonies. Between two and three years ago I started with two nucleus hives of Italians, and shortly after my brother bought four more, and these we joined; bought 20 hives of brown bees, and Italianized them, and God blessed us in our undertaking. To-day we have a nice apiary, and things look promising. We got one of your ten-inch machines, and it works splendidly. This season so far has been a splendid one; and as we have about three months more to run before the season is over, we expect to get a good store.

Brisbane, Australia, Feb. 10.

A. A. MILES.

TWO INCHES UNDER THE BROOD-FRAMES A FAILURE.

Two years ago I hived a swarm on 8 Simplicity frames, raised two inches from the bottom. They did not build any comb below the frames that year.

The next spring they built comb to the bottom of each frame. For a small apiary, I can find nothing as handy as old phosphate-sacks for smoker fuel. I make them in rolls about 14 inches long, and 2 thick. I use them in the Clark smoker, first taking out the grate. When I am done using it I dip the fire end in water, then the rest is saved for another go. I wish you would thank Dr. Miller for advocating the Clark starter fastener. It is as far ahead of the Parker as the movable comb is ahead of the old box.

W. W. KULP.

Pottstown, Pa., May 22.

SHADE FOR HIVES OUT OF OLD SUGAR-BARRELS.

For a shade for my hives I get a sugar-barrel; and after nailing through the end and middle hoops with a small wire nail, so as to fasten all of the staves, I knock the head out, then saw the hoop in two, making two half-barrels; and after clinching the nails they are ready for use. The covers are light, easy to handle, and give good ventilation between cover and top of hive, and they do not blow off as easily as a flat cover. If they are properly nailed and clinched they will last a long time, and are not expensive.

A SIMPLE WAY TO WATER BEES.

I take a tub (I suppose any thing else would do), tie a piece of burlap over it, put in a piece of brick or stone that will keep it down in the center; and then fill in with water until it comes up about one-third of the way on the burlap, which leaves a large surface for the bees to alight on. It is only occasionally that a bee gets drowned. One advantage of the tub is, it does not need looking after, except occasionally. Try it, and be convinced.

Dow City, Ia., May 17.

M. G. WIGGINS.

Friend W., you have given us two bright ideas. Thank you.

BEES WINTERED WELL, BUT "SPRINGED" BADLY.

Bees wintered out of doors well, but springed badly; but they are in good condition now; but, alas! very little basswood will bloom, and we all know what that means—no white honey from Central New York this year. We are in hopes to make it up in buckwheat. We should be pleased to see you about August 15th, and show you how W. L. C. takes care of 600 colonies with one assistant, in 7 different places.

W. L. COGGSHALL.

West Groton, N. Y., June 8.

We should be glad to know, friend Cogshall, how you, with one assistant, manage 600 colonies in 7 out-apiaries. What kind of a hive do you use? Are your frames suspended, closed-end, fixed, or not fixed with spacers?

NECTAR GOING TO WASTE; A GOOD FLOW OF HORSEMINT.

Never before did I see such a flow of nectar from horsemint; in fact, my bees are gathering honey faster than they can build comb to receive it. I have 150 colonies. I run about 35 for extracted honey, the rest for comb honey in one-pound sections. Some of my extracting two-story Simplicity hives have a case of sections above the extracting story that I put on a few days ago, and are about full of as beautiful honey. Oh! I wish you were here to visit our mint-fields, and just see the quantity of it. I know you would say, "I wish my bees were here to gather some of this flow that is going to waste." There is acre after acre resembling

fields of wheat. Thousands of pounds are wasting here for want of bees to gather it. The flow is not half over yet. The tested queen I got of you is a splendid one. Her bees have about finished two cases of 1-lb. sections. Each case holds 28 sections. Lexington, Tex., June 8. W. S. DOUGLASS.

Friend D., it would afford me great pleasure to visit your mint-fields. But are they not an indication of bad farming? So long, however, as they will grow and flourish, let us by all means utilize the honey they produce.

A HONEY THAT CANDIES IN THE HEAT OF THE SUMMER.

Friend Root:—Can you account for honey candying in the summertime? This summer we extracted about 1500 lbs. This was in November; and at Christmas time it was candied without the least signs of any moisture on the tops of the cans. From November to December the thermometer was ranging from 85 to 100 degrees in the shade. You will see by the label inclosed that we tell our customers that the honey will candy as soon as cold weather begins; but when it candied in the full heat of summer we were nonplused. I may say that this honey was gathered from the red mangrove, but it is a beautiful white honey.

A. A. MILES.

Hemmant, Queensland, Aus., May 9.

Friend M., we have for years back, every little while, had reports of a kind of honey that candies, even at a summer temperature; and this honey does not seem to be confined to any particular plant, or to any particular locality. It seems, however, as a general rule, to be confined to certain localities. I do not know of any remedy, unless it is to utilize such honey for feeding and brood-rearing. The bees can use it about as we use honey candy, such as they use when they need feeding in winter.

DID THE BEES TRANSFER THE EGGS FROM THE QUEEN-CELLS?

Eight days ago I found one colony queenless, with some young bees about hatching out. There was no young brood, but plenty of bees. I got a frame full of brood in all stages, and I put it in with them. This day I find four nice queen-cells on it, and on the frame next to it I find three cells. Did the bees transfer the eggs?

Clearfield, Pa., May 21.

J. MCGAUGHEY.

Yes, friend M., the bees did transfer the worker eggs. The same thing has been several times reported. You will find it in our text-books and in the journals.

THOSE JARS FOR EVAPORATING HONEY OUT OF THE HIVE.

Friend Root:—You inquire the size of those jars I speak of on page 413. You notice I said lard-cans and stone jars. There were two 10-gallon cans, one 6-gallon jar, some 4-gallon jars. The two cans I emptied late in the fall, and refilled them from screw-cap cans. The honey from the latter was candying rapidly at the time, while the former had not commenced to grain. The 6-gallon jar was the last one disturbed. When I emptied it in January, the honey was candied at the bottom and clear at the top. At the same time, some 2½-lb. and 5-lb. tin pails of honey, with lids, filled in August, were mostly beautifully liquid. From the above I think

with you that honey in open gallon vessels, exposed to a daylight temperature, ranging about 100 degrees for two to three months, would become so thick it never would candy. G. F. ROBBINS.

Mechanicsburg, Ill., June 5.

THE NICEST HONEY; BURR-COMBS AND THICK TOP-BARS.

I have kept bees for eight years. I have the name of having the nicest honey around. I had 3000 lbs. last year from 28 swarms, spring count. The most I received from one colony was 212 lbs. I sold the most of it around home. It averaged me 13 cts. per lb. I also sold some extracted honey. I have had five new swarms. The first came out the 23d of May. I prefer the thick top-bar. I have a few of ¾ top-bar frames, which, with ¼ in. between frame and super, will not allow burr-combs to any extent. O. H. PIKE.

Mount Vernon, Mich., June 16.

GONE BACK TO FIXED DISTANCES.

I began bee-keeping, or rather, perhaps, keeping bees, in 1850; but when I read the many learned articles in GLEANINGS I see I am yet a novice. I have been much interested in the discussions on fixed distances for frames, because the first frames I ever made I made with projections on one side only; thus: This gives me the distance I wanted, and is right whichever way they were turned. I used this pattern of top-bar for many years, and was satisfied with them till the much-esteemed editor of one of our bee-journals told me that fixed distances were very objectionable, so, of course, I straightway cut off the projections; but in less than one season I got tired of spacing frames with my fingers, and often squeezing bees between the combs, in pushing them together, so that I drove a nail for a spacer, on one side only. I manage very well with them. A nail on one side is better than on both, as you have not to be so particular where you put them, and it's just half the work. Bees have been doing pretty well here lately on wild mint. Every one has had difficulty in getting swarms to stay. I lost three, but now give them a frame of brood, and they stay. GEO. E. HAILES.

Syble, Tex., June 6.

NO LOSS IN WINTER.

I put 53 swarms into the cellar, and took out 53; and after they had been out a short time they began to double up, and they kept at it for three weeks, and 16 is the number that went in with other swarms. I have not lost as many as most of my friends here. A. E. BRADFORD.

Hammond, Wis., June 3.

LOCALITY, AND HOW IT AFFECTS BEE-HIVES.

Why don't you get Prof. Cook to tell us all about the little troublesome flea, and how to master him? Mr. Root, if you and friend Doolittle were keeping bees in Texas, you would not tell bee-keepers to paint their hives white and leave them in the sun. Experience would teach you better. Bees have swarmed a great deal, but no surplus yet.

Milamo, Tex., May 23.

G. W. BEARD.

BEES ON ALSIKE; RAPE SOWN AMONG THE OATS.

Mr. Root:—Yours of the 7th was received the 14th, and the goods last Thursday. Every thing was in good shape. The alsike clover seed you sent me last spring, a year ago, you ought to see how big it

is, and how the bees hum over it. The 1 lb. of rape you sent, I sowed last spring, and received no benefit therefrom. The bugs took it until the weeds came up. Then we gathered a few seeds, which I threw broadcast over my oats this spring, and I believe that every seed has come up, and is all yellow all over. Whether the oats is a bug-protector, I know not. Bees have not done well so far—at least mine. It has been too rainy for them.

PETER J. PETRY.

Port Washington, O., June 16.

REPORTS DISCOURAGING.

HEAVY LOSSES IN BEES.

Eighty per cent of the bees died in this vicinity last winter. I lost about 97 per cent. The losers all wintered in cellars. C. M. LINCOLN.

Rupert, Vt., May 20.

DISCOURAGING FOR IOWA.

Up to June 3d the weather was very dry; the clover was burning up with the hot winds. We have had but little rain for the last two years, and this spring has been excessively dry, and now the weather is cloudy; for days, damp, misty, and chill. Bees have been nearly starving, and to-day they are putting out drones. There is considerable white clover in bloom. We need lots of rain and then sunshine. The spring was cold, hence our bees did not breed as rapidly as desirable. I fear our harvest will be very limited. I think GLEANINGS is getting better and better, when I compare our GLEANINGS of years ago with GLEANINGS of to-day.

Lucas, Ia., June 10.

E. B. MORGAN.

HEAVY LOSSES IN WINTER; DUG-OUTS VERSUS CELLARS.

Bees in this part of Minnesota have come out rather poorly. One man near here put 30 colonies into the cellar last fall, and now has only one left. Others have lost half of their bees, and but few have come out without heavy loss. Bees are doing nicely now, although it is quite wet for them. I have 40 colonies now. I have had good success with the bees for the last few years. Three years ago I went from 42 to 6. I was then trying to winter bees in dug-outs in the bank, but found that that was a failure. I then made a cellar for them. I bricked it up inside, and put in a cemented floor, and a frame inside of the brick wall, and lathed and plastered on the frame. Since then my bees winter in good shape. I. C. SMITH.

Lone Tree Lake, Minn., June 13.

PROSPECTS DISCOURAGING.

It has been one of the worst seasons for bees, for a number of years. Last fall, bees went into winter quarters in apparently good shape. The losses last winter were very heavy. While your humble servant did not lose a swarm, many have lost heavily. Some have lost about a quarter, some a third, some a half, some three-fourths, and a few lost all, or nearly all. Of these, one lost six out of eight; one lost all; one lost 39 out of 40. Bee-keepers in this section are becoming much discouraged. All through the month of May we had only four bright days—no chance for any thing from fruit-blossoms. Dandelions are gone, and hardly enough honey is gathered for brood-rearing. Raspberries were killed last winter or spring, so there is nothing to be

had from that source. Up to this date there is no clover in bloom. Most of it winter-killed, so that at the present date the bees can hardly hold their own—not a spoonful of surplus yet. The season may yet open up very favorably. Time will tell the story.

D. NOBLE.

Clintonville, Wis., June 16.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

CONDITION OF THE BEES.

OUR spring has been very backward, and it began to look as if the summer would bring us no nectar. White clover has been in bloom now for nearly two weeks. The farmers round about report seeing more of it than they have seen before in a great many years, yet, until the 22d inst., no honey had begun to come in. Prior to that time the bees had been living from hand to mouth; in fact, we had been feeding all of the colonies more or less, to keep them from curtailing brood-rearing, if not from actual starvation. Again, the bees are at work storing honey pretty rapidly just now, the 23d.

THICK TOP-BARS.

The great rush in other departments of our establishment, together with the sickness of clerks, has prevented my experimenting in the apiary as much as I ought to have done. I finally sent out some thick top-bar frames. They were wired on Keeney's plan, filled with foundation. It is hardly time yet to tell how we shall like them, although we feel pretty sure that they will never sag.

OUT-APIARIES.

By reason of the great rush in other departments, as above spoken of, and the backward spring, we have not located an out-apiary this season. On account of orders for bees and queens, we shall need all the bees we can scrape up at home.

CARNIOLANS.

We have now a colony of the above bees in our apiary, that are as gentle and nice to handle as any Italians we have in the apiary, and this colony bred pretty heavily in spite of the backward season. Mr. Spafford says, however, as to their disposition, they are at times a little more nervous than the Italians, he thinks. They seem to be a trifle larger in size. That was the impression I had formed of those we had a year or so ago. These Carniolans were obtained of Dr. S. W. Morrison, who is now about to sell off all his Carniolan apiary, being obliged to go to Colorado Springs on account of the ill health of his wife.

Since writing the above I have tested a little more the temper of the Carniolans. We always open the hive now without smoke. We made quick motions over the frames, pointed our fingers at them—in fact, did every thing we could to irritate them, except to jar the hive, and they are certainly gentle. They prove to be good comb-builders, good breeders, and have as much

honey in their hives as any other colony in the apiary. I shall be very glad to believe that the six or seven colonies of these bees we have tested heretofore have not been a true type of this race.

SOLAR WAX-EXTRACTOR.

A short time ago we bought about two dozen hybrid colonies, on natural-built combs. The latter were so poorly built out that we put them in upper stories above the queen-excluding zinc, with the queen and a majority of the bees below. After the brood hatches we put them in the solar wax-extractor. We have been using it every day. The solar wax-extractor is certainly one of the conveniences in a well-kept apiary.

CROSS BEES; A LIVELY FRACAS.

For experimental purposes, one of our hybrid colonies we had decided to change from one hive to another. After the combs were transferred, as is usually the case, there were quite a lot of bees clinging to the inside of the hive. As we have done a good many times before, we inverted the old hive before the entrance of the new one, and gave it a bump to jar the bees out in front of the entrance. Then a lively fracas ensued. Almost every one of those bees flew up into the air immediately, and began stinging vigorously. In fact, the air seemed to be black with them. I confess I do not like to run from bees when I have a veil on; but having only a thin coat on, the little scamps punctured my back and arms right and left. I finally took to the evergreens in inglorious haste, leaving our apiarist, Mr. Spafford, to take care of himself. To get rid of the bees I circled around the evergreen trees two or three times. After coming back to the old place I found that Mr. Spafford had got his smoker, and was making free use of smoke. Now, it so happened that there was a small hickory-tree back of this row of evergreens; and very soon, very much to our horror, we heard the cry of children. Mr. S. and I both ran to the tree, and found that Huber and his playmate Mattie were pretty near the top of the tree, and those hybrids, evidently, had left us and attacked those helpless children with bare legs and bare heads. Frantic with pain they clambered from one limb to another. I yelled to Huber to jump into Mr. Spafford's arms, and then I ran for the other boy. He was then ten or twelve feet up the tree. When he was within about eight feet I called out to him to jump. He hesitated a moment, and then finally did as I requested. I caught him safely in my arms. By doing this we left the bees eight feet up in the air, buzzing around whence their victim had suddenly disappeared. Huber, fortunately, had received only one sting; but Mattie was stung something over a dozen times about the face, head, and neck. The probabilities are, that the bees attacked Mattie first, and, drawn on by the scent of the poison, they began giving him an unfair dose. After reaching the ground safely, the boys needed no invitation to scamper to the house, which they

did, followed by your humble servant. Both boys were crying with pain. I quickly removed the stings by scratching them out, without pressing the poison-bag. There were so many stings in Mattie's hair that I was forced to resort to a fine comb. We finally removed them all, and his face was bathed, and he was taken home. The stings had no other effect than to give him a good big swelled head and fat cheeks. Huber had received only one sting, and it did him no very serious injury. For some reason, Huber is very sensitive to the effect of the poison. His mother thinks, if he had been stung as much as Mattie was, it would have killed him. However that may have been, we are glad that it was no worse than it was. Mattie has been stung a good many times, but does not seem to be affected much by the poison.

After removing the stings I went back into the apiary, and found the air was full of mad bees. I carefully adjusted my veil and went out among them again, having first prepared myself with a couple of flat boards, about 10 by 15 in. These I clapped together, cymbal fashion, in such a way as to kill half a dozen at every stroke. I continued this for ten or fifteen minutes, until I killed all or nearly all the mad bees. The apiary again became quiet, and all was well.

One other time, by some little hook or crook we had gotten the bees stirred up so that the air was literally black with the infuriated insects. We did nothing further than to close the hive up at the time, and avoid that part of the apiary as much as possible. There was a whole week that we could not go anywhere near that hive. They stung every thing and everybody that chanced to come within a few yards of them; and for two or three weeks after, they gave us more or less trouble. After the recent occurrence above related, I concluded that all the angry bees were probably in the air; and that, if they were going to be troublesome for a week or more, and possibly sting a valuable horse, or get after more children, they might just about as well die then as at any other time, and so I proceeded to kill them as above stated. Mr. Spafford was in another part of the apiary working, and he told me afterward, as he saw me with the two boards clapping and smashing the bees that were about me, that there was a literal swarm about my head. I stood and kept killing the bees until they were all dead. The apiary was then as quiet as ever, and we have had no annoyance since.

It is a well-known fact, that one or two angry bees will follow an apiarist about the whole day, and possibly annoy him other days, if they are not killed. Killing them puts an end to the annoyance, and allows the apiarist to go about his work among his bees with his veil raised up, enjoying all the comfort he has a right to have. It does not pay to let those angry fellows live after they are so thoroughly stirred up. I presume I must have killed, at a rough guess, some 200 or 300 bees; and what was the loss of that many bees compared to the continual annoyance of being stung every time any

one came within a few yards of their hive? Their sisters in the hive, not having knowledge of what their sisters outside were doing, seem to be fairly quiet with ordinary precaution.

MYSELF AND MY NEIGHBORS.

Lay up for yourselves treasures in heaven, where neither moth nor rust doth corrupt, and where thieves do not break through nor steal.—MATT. 6: 20.

THERE are three things that I wish to talk about to-day. First, "our homes;" second, "our neighbors;" third, strawberries; or, if you choose, the cultivation of strawberries. Can any one lay up treasures in heaven by raising strawberries? I feel sure he can; and the very thought of it animates me and gives me energy, enthusiasm, joy, hope, and finally health—yes, health. Health comes as a result of honest enthusiasm in some praiseworthy object, a great many times, when it will not come in answer to the combined skill of our greatest, wisest, and best physicians. Perhaps I might as well tell you, to commence with, that neighbor Terry has been for some time hard at work writing a strawberry-book. Perhaps it was nearly a year ago that I told him I wanted him to get a good ready, and write me a strawberry-book very soon. I was not much surprised when he replied that that was just what he would like to do. I do not know but he said he had been thinking of it. When I met him at one of our institutes he asked me if I had considered that he was only a very novice in the berry-business. I told him I had, but that I would give more for his fresh enthusiasm, even if he did not know so much, than I would for something written by some of the veterans who had lost their enthusiasm, and to whom the subject had become an every-day affair. There is something wonderfully interesting in seeing any one take up any of these industries, when a great part of it is new to him. I like to see a boy or girl who has become excited, and is full of energy over bees, strawberries, chickens, or any of these outdoor industries. As I look back and think of the enjoyment, and the new thrills that have come as I have taken up each new subject in turn, it makes me feel young again.

Well, when the first chapters of the strawberry-book came we were so full of business I did not pay very much attention to them. I knew that, when the printers got ready to take hold of them, I should have to read them any way. In fact, I have become so tired of reading letters and following out the different lines of business through the letters, that I do not know but I have lost energy somewhat. Before I got through with the strawberry-book, however, it all came back. Why, in the concluding chapters I could hardly sit still. I looked at my plants out in the plant-garden, and I looked at the ground on the hill by the windmill where I am preparing to plant berries, and I could hardly contain myself. Before I got many pages further, I got into a fever to visit friend Terry. But there were the letters piled up, many of them grievous

complaints because the writers had not got their goods. I could not be spared one whole day, and I did not feel as if it would be right for me to desert my post so long. I did, however, write to friend Terry that I wanted the privilege of dropping in upon them some night between nine and ten o'clock; and I wished them, also, to let me go back about seven or eight o'clock in the morning. I bade him tell his good wife that all the preparation she need make for my entertainment was plenty of bread and butter for breakfast. With the berries I could help myself to, I should be quite satisfied and happy. Then I counted the hours until a reply should come. A reply did come—not in answer to my letter, however, for it was written before my note had been received. Here is a part of friend Terry's letter:

Friend Root:—Our patch is a grand success, bringing us about \$15.00 a day. We get our price, without a bit of trouble, in spite of great competition. Plenty of room up above. T. B. TERRY.

Hudson, O., June 18, 1890.

I received it just before noon. Friend Terry lives about 25 miles from us; and a little before four o'clock, one of our Clydesdale horses was standing before the office, waiting for me to get the letters looked after so I could be spared until the next day at noon. My wife admonished me that the barometer was falling, at a pretty good jog. But the strawberry fever was too strong to be allayed by a summer shower, so off we started. My teamster has always been rather skeptical in regard to Mr. Terry's farming; and I am sorry to say that a great many farmers and teamsters throughout our land are somewhat the same way, and yet I do not believe that they could give any good reason for it if they were to try. I rather enjoyed accepting his invitation to go along with me to take care of the horse. Mrs. Root said, before I went away, something like this: "Now, husband, remember that Mr. Terry's folks are in the midst of farming, besides taking care of their berry crop, and very likely Mrs. Terry is burdened. Stop somewhere and get your suppers, and feed the horse, so that you may make them as little trouble as possible."

We came into the pretty town of West Richfield just about six o'clock. Did I ever tell you that I have an especial liking for hotel-keepers? Well, I have. I like every thing about a hotel—especially the country hotel. I like the landlord and the landlady; I like the girls who wait on the tables (as you may remember); I like the boy who tends to the horses in the stable; yes, and I like pretty well the folks who lounge around the door and bar.* I should like them better, however, if they were busy in something good—in the line of our text, for instance. These country hotels are homes for

* When I use the term "bar" I do not mean a place where drinks are sold, as used to be the custom forty years ago. A good many of our country hotels here in Ohio do not sell any thing at the bar—not even cigars or tobacco. Perhaps the term "bar" had better be exchanged for "office." I wonder how it is with you, friends. Do the hotels in your small towns nowadays sell drinks of any kind?

homeless people; and I always enjoy seeing how well they carry out this idea.

"My good friend, we want some supper just as soon as our horse can eat his feed. We have quite a piece to drive yet, and we wish to get there before the people have gone to bed."

I was pleased to see how quickly he moved to the kitchen to tell the women-folks to start it going. Then he directed in regard to the care of the horse, and stepped briskly to the meat-shop; and almost before the kitchen door was shut we heard them pounding steak. Before I had time to become impatient or nervous, we were called to partake of the nice steak and potatoes, with a couple of fried eggs, nice sweet butter, good bread, and a good saucer of strawberries. If you want to see me have a good appetite, just let me ride twenty miles across the country. For serving us thus handsomely, the whole charge was only 25 cents apiece. The horse counted the same as a man. Now, when I get promptly served, and yet on such short notice, do you wonder that I thank God for hotels, and that I feel kindly toward hotel-keepers?

Just a little before nine o'clock I had the pleasure of telling my companion, Mr. W., that this was friend Terry's home. I watched him as he looked at the bright pretty barn and tool-house in the dim moonlight. Friend Terry was off to Hudson, with berries; but his son and a hired man welcomed us.

"You said you would be here between nine and ten; but you are a little ahead of time, are you not?" said the young man.

I always like to be ahead of time. It is a grand idea, in business, boys, to make your promises, even in traveling, so that you are on hand a little sooner than you agreed to be. You try it awhile, and see if you don't find that I am right. We were warmly welcomed by all the family, even if we did come three or four days before we were expected. Friend T. soon returned, then got a lantern, and we went to see those wonderful strawberries. The first glimpse I ever had of the Grand Rapids lettuce was by the light of a lantern. I shall never forget it. By the way, there is something wonderfully fascinating to me in going about among the plants after dark. How cool and beautiful the ground looked in friend Terry's new plantation of strawberries! The beautiful, thrifty little plants, each one as much like its neighbor as two peas can be alike, at exact distances (rows four feet apart, plants two feet apart in the rows), with all the intervening ground in process of being raked until nothing *could* live except the strawberries—why, I fairly ached to get hold of a fine-tooth steel rake, just to stir the beautiful, fine, soft rich loam. If there were any weeds, they had not come to the surface of the soil. In fact, weeds never get so as to be visible on the Terry plantation. Then we went with the lantern over to that half-acre in full bearing. I have a photograph of it that I will show you before long; but no photograph can begin to do justice to the sight we beheld. The varieties of strawberries are selected so as to have no rusty

leaves. Every leaf is thrifty, perfect, and has that bright new look that indicates a rank luxuriant growth. The whole ground between the plants is carpeted with cut straw, so not a berry can find any thing gritty or that will soil it in the least. Strawberries growing and ripening on "straw"! and, oh what clusters of them!

It seemed as if there were hardly room enough for them to ripen without lying piled up on each other. Paths were provided for the pickers, a foot wide; but these paths were also filled with straw. The Sterling, Cumberland, Gandy, Downing, and Bubach, kept their berries out of the path; but the wonderfully productive Haverland could not be satisfied with piling the berries up in the row, but it just kept pushing its great long stalks full of fruit clear out into the path; and it was very difficult indeed to walk in the paths without stepping on these great beautiful handsome berries. Did anybody ever see such a plant as the Haverland? One reason for wanting to visit friend Terry was, that I wished to see whether his Haverlands were really lying in heaps around the plants, as ours were. They were doing that very thing. Friend T. is not excitable. I never saw him get very much excited about any thing. He is cool and quiet in almost all emergencies. He does not sail his hat nor get as enthusiastic as I do; but for all that he enjoys nature's gifts fully as much as the rest of us, if I am correct. Now, the catalogues have been severely censured for being extravagant in regard to many of these new things; but since I have been home I have searched all the catalogues in vain to find any thing that does *half justice* to the Haverland. It is true, the berries are rather tart, and have not very much flavor compared with some of the others; neither are they as large as some. But the berries are of good size; and with a little sugar they are almost as good as any of them. And, oh my! what an abundance! I have not any figures just now about the amount per square rod; but you will find them in the book. It seems to me that this plant is destined to bring about a new era in strawberry culture. We have had them for two years. The first year we kept our original plants so busy furnishing runners, that we did not get very much fruit. During this last spring I let the old plants go, and they were pretty well covered with grass and weeds; but when they began to set their fruit I was almost alarmed. I could not believe it possible that any plant could ripen the quantity of green berries that lay around them on all sides. But they did do it; and as fast as they turned red they increased in size to such an extent that it seemed almost like popping corn.

The lantern was put away, and we went to bed. I obtained permission to get up at daybreak, and I proposed not to disturb anybody else. The barometer's prediction troubled me a little, and so I was not surprised to hear the patter of the raindrops a little before daylight. The rain let up, however, a little after daylight, and, oh what a beautiful sight met my view! One of friend Terry's hobbies is keeping things

painted. The barn and tool-house and covered barnyard had just been treated to a coat of bright new paint. By the way, this covered barnyard has just been enlarged to about twice its former capacity. But I tell you, it is handy—especially where one has as many tools as friend Terry and I have. Friend T. has a knack of combining colors, with a small amount of architectural curves about the covered yard, that makes it wonderfully pleasing to the eye. The fence before the house was also neatly painted, and in good repair; gates all working nicely. A gravel walk led around to the front door, and a gravel driveway on the other side of the lawn led around to the rear of the house. Friend T. has a gravel bed, or bank, on his own farm, and therefore it is not a very expensive matter to have neat gravel walks all about his home. The painters had also been at work about the house; and when I suggested that most of us would think that it did not really need painting, he remarked that it was *cheaper* to paint *before* buildings really needed it, in the common acceptation of the term; and there we have the same story over and over again all over friend Terry's premises. Every thing is done *before* it begins to suffer from lack of attention. The weeds in the strawberry-bed are killed *before* they get to the top of the ground. His fourteen-acre potato-field is tilled in the same way, even during this remarkably wet season. The potatoes stood so regular throughout the field that one might think they were spaced by machinery, which, in fact, they were, by the machinery of the potato-planter. Instead of there being hills of potatoes, however, there was a single stalk standing up like a little tree, each one just like its neighbor, as in the strawberries. This comes from the "single-eye" idea. If we let a great lot of sprouts grow in one hill, it is like having eight or ten stalks of *corn* in a hill—you have only nubbins instead of fine large ears. This single potato-stalk produces only a few potatoes; but as these are not crowded at all, they are large, fine-shaped ones; and his potatoes, like his strawberries, command an extra price. Some time last fall I sent friend Terry an order for 25 bushels of potatoes, to be kept for seed. I was too late. They were sold out, and I was astonished to learn during this visit that 280 different people sent money for potatoes, after the potatoes were gone. That is worse than any thing we have done—or *better*, whichever you choose to call it. The receipts for strawberries during the day I was there were something over \$23.00.

When I mention about friend Terry's farming, many people reply at once, "Oh, yes! friend Terry has got money, and can afford to hire all the help he needs."

Now, this is a sad mistake. One great feature of Terry's farming is to manage with the very smallest amount of help. If I am correct, he has only one hired man, aside from himself and boy, and the assistance his wife and daughters give in berry-picking. Many people ask, with wonder expressed in their eyes, "Why, do Mr. Terry's *daughters* work outdoors in the straw-

berry-beds?" Yes, my friend, they do. After they had finished their education, they, like most young ladies, wanted something to do. They might teach school, clerk in the store, or perhaps find a situation in an office in some of our large cities. They preferred to stay at home, however, and work with their father, rather than to be "bossed" by somebody else who is not their father. Do you blame them? Their father suggested that they raise strawberries, instead of teaching school; and I think they are getting more money than most schoolteachers. I did not see them picking strawberries while I was there, because it rained. As they were living at home, and working for their father, they could work when they chose. I looked several times longingly at the beautiful large piano that has recently been purchased, and which stood right in sight; but so many important matters crowded I hardly dared ask them to treat us to some music. Now, I suppose women-folks should be free to choose an occupation, just as men are; but if it were myself, or if it were my daughters under consideration, I should say, "Give me strawberry culture a hundred times over, rather than schoolteaching or any of the other employments open to women-folks." When I mention these rural pursuits, and the wonderful success some have met, the constant objection raised is, that the markets are frequently overstocked. Strawberries a week ago sold in our town at 5 cents a quart. Ours, however, when freshly picked, brought 8 cents readily.

I now wish to relate a little incident illustrating the character and quality of friend Terry's berries. I think it was on Tuesday, June 17, that the quantity of berries became so great that friend T. took a small load to Akron, while his son went to Hudson. He feared there would be more than the town of Hudson could manage. As he approached Akron he met farmers coming home, telling him there was no sort of use in carrying another strawberry to Akron that day. He, however, pushed ahead, but found it all as they said. Stacks of berries were piled up in front of every store and grocery. The troubled proprietors were standing out on the street, trying in vain to get an offer. He drove to the place where he was accustomed to trade, and asked them to look at his berries. This they positively refused to do, saying they were in trouble already because of having been induced to purchase beyond what prudence would dictate. The proprietor, however, finally consented just to look under the cover of the drawers. Friend T. assured him he need not buy, but that he would like to have him *see* some of his product, as he might at some *future* time wish to bring him some berries. He reluctantly approached the spring wagon. Friend T. expected to see him an astonished man when he raised the cover; but he was not prepared for his sudden change. The berries were sold at a price away above those already standing on the sidewalk. When he got home, his son had orders for all the berries they could pick, from the Hudson dealers; and on going to the postoffice he

found a letter from the Akron man, imploring him to bring four bushels Thursday morning, without any possibility of failure. Mr. Terry was obliged to decline the order. There were not berries enough to go around. When I was there, the Gandy had just begun to bear. Friend T. had taken a sample to Hudson, and they brought a *dollar a peck*, without any trouble. No wonder, for they looked like luscious peaches or plums, more than like strawberries. As we stood by the buggy, ready to bid our friends adieu, I ventured the remark, "Friend T., why don't you have 14 acres of strawberries instead of 14 acres of potatoes? They would not be very much more trouble, and then think what a lot of money you would have."

He shook his head, and smiled. I don't remember just what he said, but it conveyed an idea to me something like this:

"Fourteen acres of strawberries would make my home a thoroughfare. Its quiet and sanctity would be invaded. My wife and daughters, instead of having this quiet, pretty home all to themselves, would have seclusion and peace no longer. It is true, I might make more money; but I am not working for money. It is not the end and object I have in view. I am a farmer, and I always expect to be one. I love my work because I am enabled by it to demonstrate what farmers' homes may be, compared with what many of them are at the present moment. I want to see farmers' boys and girls find something to do at home on their farms. I want them to love the farmer's home, and to feel proud of it. I want them to find peace, comfort, contentment, where too many of them have found only drudgery, privation, and long hours of toil. I want them to work at home on the farm, and to learn to lay up treasures in heaven, as well as treasures on earth; and I want to show them the buried treasures that lie unused only a little way below the surface of the soil—just below the surface of so many farms, where at present we see only an unsightly and dreary waste of weeds and disorder."

Now, my good friend Terry did not say any thing of the sort. He is not as talkative a man as I am, and he did not say very much about it, only that he did not want 14 acres of strawberries, with their attendant care and bustle. In going all over the premises, all over his home, and talking with his wife and children, one was impressed at every step that he is not bent on making money. It seems, however, that the kind Father has provided the money. That little text that has been for so many years a hobby of mine, explains it all: "Seek ye first the kingdom of God, and his righteousness, and all these things shall be added unto you." So long as friend Terry is working with all his might and main to emancipate the farmer from the drudgery of ordinary farming, God will see to it that he has the wherewith to do his work. Moody once said that he believed that God would furnish his ministering servants with the wherewith to carry on their work. I said, as soon as I heard it, "I, too, believe it is true."

Before I left I told my friend that, although there were to be more chapters to the strawberry-book, he could have his pay for what he had done, just as well now as at any other time; and I added something like this:

"Friend T., I have been having many heavy cares and burdens to bear during the past few months; but I am glad to be able to say that lack of funds has not been one of the burdens."

He replied:

"Thank you, Mr. Root; but I do not need it. A lack of funds has not cramped me and troubled me in my work either;" and a pleasant look on his face impressed me with the thought that a spirit of thankfulness to the great Giver above was in his heart as well as mine, and gave an added enjoyment to his work.

We bade adieu to that pleasant home. The surrounding homes for quite a little distance seemed to have caught friend Terry's spirit, for they were well-to-do, progressive farmers; but the potato-fields right over the fence from friend Terry's were as different from his as anything you could well imagine. Notwithstanding this, they were rather better than anything we had seen in our drive of 25 miles across the country. I looked in vain on this side of the road and that, but no such farming greeted us anywhere as we saw there.*

We took a different route home. You never see me going the same road twice, if I can avoid it. At Cuyahoga Falls we called on the veteran strawberry-man, Mr. Matthew Crawford. Friend C.'s whole business is strawberries—not raising them for the market, but testing different varieties, and raising plants for sale. I saw something there which I had never seen anywhere else, and perhaps I shall never see it again—little beds of two or three rows, of all the kinds of strawberries known. In some places great luscious berries were rotting on the ground. When I remonstrated, he said so many were coming daily to discuss the different varieties that he left a few so as to be always able, during the season, to furnish specimens of dead-ripe fruit. I mentioned ever so many kinds I had heard of, but I was promptly led to the very variety in question, where I saw it doing its best. Friend Crawford is a devoted, faithful Christian. In fact, it shines forth in his face, looks, words, and actions. As my paper is getting long, I shall be obliged to pass over this visit briefly. As an illustration of our talk I give the following:

"Friend C., will you please show me the largest berry known?"

"With great pleasure, Mr. Root. But do you really think you want to invest in the largest berry known?"

"Why, surely. If it is a good one, why should I not?"

* *Later.*—Since our visit I have received the following on a postal, from friend Terry:

Well, it dried off Saturday, so we sold 10 bushels of berries, \$26.00; and Monday 13 bushels, \$36.55. Not quite so thick to-day, but we got a bushel of Gandy's Prize, that sold for \$4.00. I had a photo taken. The Gandy will not hold out long.
Hudson, O., June 24. T. B. TERRY.

"Yes, it is a good one—that is, fairly good. Come and see."

He parted the leaves, and there, to my great astonishment, was an immense fruit that I should hardly have called a strawberry had it not been for the surroundings. Instead of being like other strawberries, it was much the shape of a very badly scalloped tomato; and I declare, the berries were pretty close in size to some tomatoes. I picked a great big one and took a bite. The quality was very much like that of the Bubach; but there was not a single specimen but that was knotty and gnarly, with protuberances growing out of one side or out of another. At first I declared I would make a planting of it; and then it occurred to me that everybody would object, and prefer something a little smaller, of good shape, and firm enough to ship—something like the Gandy, for instance. If one wanted, however, a great lot of berries, and something that could be picked very quickly, I rather think this would be the berry. My companion told me that he had found ten of them that would make a quart, and he thought it very likely that he could do it then and there. As its shape suggested tomatoes, I asked:

"Friend C., why is it not probable that some time we shall have a single strawberry combining so many of the desirable qualities of others that only one variety will be needed—like the tomato, for instance?"

"I have thought of it a good deal, Bro. Root; and, by the way, I am very much rejoiced to know that we have finally one tomato summing up all the good qualities to such an extent that no other is needed. I am myself, at present, planting only one kind of tomato, and it seems now that I may never care to plant another kind."

I almost held my breath as I asked, "Why, friend C., you astonish me. Will you please tell me the name of that one tomato that you put in place of all the long string of tomatoes known to seedsmen and catalogue-makers?"

What do you think he said? He smiled just a little as he replied, "The Ignatum."

I did not at the time know whether he was aware that I first gave it to the public, but he said he had heard it so stated.

"Now, Bro. Root, I have something to tell you that will greatly please and interest you. I do wish you could meet friend Loudon, who gave us the great big strawberry you hold in your hand, and he has given us almost numberless other valuable strawberries. You will notice that I have numbered them in different places over my ground—No. 4, No. 8, No. 75, etc. Well, friend L. is a Canadian. Some years ago he was very low with consumption, and his case was pronounced by nearly all the physicians incurable. There was nothing before him but to get ready to die. As he was a good man, his friends could not bear the thought of losing him, and his children could hardly give him up. A son of his was interested in strawberries, and he begged his father to stay outdoors and get interested in berry-growing, suggesting that, if he should get as full of enthusiasm as some of

them did, it might make him well." I began at once to think of our good friend Mrs. Axtell. "The father very quietly assented, and placed himself as pupil under the son. In a little time he became deeply interested in the matter of perfecting new varieties. At present he has done more work of this kind than perhaps any other man in the world; and this season," so our friend Crawford went on to say, "he has a whole half-acre covered thickly with plants, and each plant is a different seedling from its neighbor. These are to be tested, with the hope that they may furnish the world something better than we have already." Those who have made experiments in this line can conceive how much of an undertaking is such a project; and the outcome of it has been that he has regained his health, and although he is quite an old man now, he will probably live for some years yet. So you see it is not only *worldly* gifts which shall be given to those who seek first the kingdom of God and his righteousness, but the promise seems to include health; for friend L. has found a new lease of life in propagating new and better varieties of strawberries for his fellow-men. I do not know whether he is rich or not. It may be that, like Terry, he does not *care* to be rich, but holds fast to the text of our talk to-day.

Lay up for yourselves treasures in heaven, where neither moth nor rust doth corrupt, and where thieves do not break through nor steal.—MATT. 6: 20.

EDITORIAL.

So is he that layeth up treasure for himself, and is not rich toward God.—LUKE 12: 21.

GLEANINGS TEN THOUSAND STRONG.

WE are happy to announce to our readers that we have now on our books 10,000 subscribers, the exact number being 10,002. There is such a call for sample copies that we are now printing nearly 11,000 journals each issue. In fact, we have been doing this right along through the year. While we have been slow in reaching 10,000, we are glad that we have been able to hold our readers. Somehow or other they stick by us, and we hope to stick by them. Advertisers will please take into consideration our large subscription-list. Three thousand is usually a large list for a trades journal; but *ten thousand* is almost phenomenal.

GARDENING IN JULY.

IF you have fine soft mellow ground, well manured and well drained, you can get a good crop of almost any thing, providing your seeds or plants are got right into the ground without a moment's delay. One of our agricultural papers suggests that the 1st of July is generally about the best time to sow buckwheat in any *patriotic* neighborhood. Do you open your eyes and mouth at the latter remark? Well, his explanation is, that the bombardment universally carried on is almost always productive of a thunderstorm; and that, if it does not rain on the 4th, it surely will the next day, and this will give your things a start that will be pretty sure to make a crop.

BUSINESS AT THE HOME OF THE HONEY-BEES, JULY 1.

Our saw-room reports all orders filled, with the exception of sections; and as we are now running almost all our force on sections, both upstairs and downstairs, still running day and night besides, we hope to be up on sections by about the time this reaches you; and we never mean to be caught in such a predicament again, if our friends will overlook our past delinquencies of the season. We do not mean by this that you are to let us off "scot free." Tell us what the damage has been and we will try to make it satisfactory.

SELLING SECRETS.

It seems we have not quite finished this matter, judging from the large number of letters coming daily. From among them we select the following:

FRIEND ROOT.—You may remember, perhaps, my telling you, when you honored me with a visit at Niagara, of the influence your writings had had on me. I may say that that influence has not waned; but there is a question concerning the Wilford Hall matter that I should like to have you explain; or, rather, give your views on. I, like yourself, and hundreds of others, through an advertisement in *Messiah's Herald*, of Boston, and the personal indorsement of the editor, signed the Pledge of Honor, and sent the \$4.00; but I was considerably taken back when I read your editorial in *GLEANINGS* of May 15, characterizing Dr. Hall as a swindler; and I received a further surprise when, in the next issue, you gave the whole "secret" (?) away by quoting Dr. Kellogg. Now, what I want to know is this: Have you not violated your pledge by publishing what you did? If so, why am I not at liberty to lend my pamphlet to any of my friends whom I think such treatment would benefit?

Waterloo, Ont., June 16.

GEO. CORK.

Thanks, friend C., for the kind compliment you pay me. If I were you, I think I would not show the little pamphlet to my friends, under the circumstances. You can, however, show the copy of *GLEANINGS* in which I copied from Dr. Kellogg, as much as you choose. Some of the friends still insist that I violated my pledge, and if in no other way by saying to the world that Dr. Hall's secret is the same as what I quoted from the doctor book. Very likely there is some ground for the claim that I have not kept my pledge to the strict letter. Let us try making the matter plainer by an illustration: A man pays you a debt, and you give him a receipt in full. You afterward discover that the money you received from him is counterfeit. Suppose he should still flourish his receipt in full, and claim that he owed you nothing because he had a receipt with your signature at the bottom. In one respect he is right. But you reply: "Look here, my friend, that receipt was given to you with the supposition that the money was genuine. You obtained it by fraud." Property or papers, or any thing else, obtained by fraud or by false pretenses, can be recovered by law. Dr. Hall obtained our signature to that printed promise by false pretenses. Some of the friends go even so far as to say that Dr. Kellogg obtained his information from Dr. Hall, and that Hall is the original discoverer. But even if this were true (but it is not), Dr. Hall has been taking \$4.00 for a secret that is not a secret, for it has been for ten years or more published in Kellogg's book. Still others claim that Dr. Hall was the original discoverer of forcing water clear to the small intestine. But those who make this claim have read carelessly my extract from Dr. Kellogg's book—see page 443, June 1, toward the end of the long extract. I have carefully read all your letters, dear friends, and tried hard to find reasonable grounds for calling Hall honest; but the evidence is all before us on *printed pages*.

SUPPLY-DEALERS BEING BEHIND.

MISERY loves company, it is said; and although we regret to hear that other dealers have been be-

hind in filling orders, it is refreshing to learn that we are not the only ones who have had "an unprecedented rush." Messrs. Newman & Son are always prompt in filling orders, if any of the dealers are. The *American Bee Journal*, on page 411, says:

Like all other supply-dealers we have experienced an unprecedented "rush" during this season, and as a result we have not been able to get some lines of goods fast enough to fill orders as promptly as is our custom. We are doing the best we can to satisfy all, and are shipping all the goods we can obtain, the moment they come to hand. We hope to be able to clean up all orders now on hand in a few days, and then to resume our usual promptness, for which we have a widespread reputation.

It is indeed true that they have a "widespread reputation" for promptness. In the next column of the *A. B. J.* we find this pithy editorial on odd sizes, which we are glad to reproduce:

Odd sizes of sections, brood-frames, crates, etc., are simply impossible to get made now during the "rush." If people will use any thing besides the regular stock, they should have them made in the winter, and keep them on hand ready for use when needed. All dealers and manufacturers are now behind with their regular orders, and none will now take an order for a special size; so those who use such, and have not laid in a stock in advance, will have to do without them, and learn a lesson which will cost them more or less of their crop of honey.

Again, we notice that the D. A. Jones Co., of Beeton, Can., have been behind. In their issue of the *Canadian Bee Journal* of June 15, they say:

Orders still crowd us, and we are subjected at times to some pretty harsh letters, when we have been doing our best to get off whatever may have been ordered in each case. Our trade in foundation has been larger this year than ever before, even though some of the other supply-dealers have been selling it at less prices than we. At this moment we have about all the wax bought up which is available, and we fear that our supply is going to be short of our wants, especially if orders come in the way they have been for the past week or two. We have been very much delayed through the sickness of the foreman of our tinshop, but we are having a full force working at the present writing, and we hope to catch up soon. With the exception of one or two nuclei and half a dozen queens, all orders for bees and queens are gone forward.

Yes, we all get "pretty harsh letters," even when we are doing the best we can. Customers should not blame dealers too severely when they are urged by catalogues and otherwise to send in their orders early. We all try to do the best we can to anticipate trade; but on account of sickness, mentioned in the editorial above, on account of fires, on account of a good many other things that can not be anticipated, many times it is utterly impossible to ship promptly. The only way out of the difficulty is for customers to anticipate their needs, and order early.

SPECIAL NOTICES.

NEW HONEY.

We are beginning to have calls for new honey. As soon as you have any choice to sell, we should be pleased to have samples of extracted, with offers; also price on comb honey.

ALFALFA HONEY.

We have in stock perhaps a ton of alfalfa extracted honey, which we have received from Reno, Nevada. Now, the people here at our village pronounce it equal to any clover honey that was ever thrown out of the comb; and in order to show you how nice it is, I would request that, in making freight or express orders, you have a little alfalfa honey put in as a sample. Prices exactly the same as for clover honey in our catalogue.

MAPLE SUGAR.

We have in stock, unsold, about a ton; and in order to get it out of our way we offer it at one cent per pound less than we did in our April issue—7, 8, 9, and 10 cts. per pound, according to quality; $\frac{1}{2}$ ct. less in 50-lb. lots, and one cent less in barrel lots. What we have is mostly of the medium grades, 8 and 9 cts. We have very little of the cheapest grade, and the same in regard to the best.

WIRE NETTING REDUCED TO THE OLD PRICE.

We are pleased to announce to our patrons, that, owing to a reduction in the cost of wire, we are able, after this date, to sell wire netting at the old prices ruling before the advance the first of March. The price, till further notice, will be as given on the last page of our catalogue for Jan. 1, 1890, and later issues; namely, for 2 inch, No. 19, 4 feet wide, \$4.00 per roll; 5-roll lots, \$3 75; 10-roll lots, \$3.60 per roll; 25 cents added for cartage on single roll shipments from New York and Chicago.

14-INCH GLOBE LAWN-MOWER FOR \$5.70.

In laying in our stock of mowers for the season we have to judge from sales of previous years what proportion of sizes will be needed. This year has not followed last very closely, and we have had a large call for larger and smaller sizes, so we have had to order more, and we have a surplus of 14-inch on hand. We consider this the best size of the five. However, to reduce this surplus we will, during July only, sell a 14-inch Globe mower for \$5.70, which is 25 cents less than regular price.

IGNOTUM TOMATO-PLANTS.

We have finally rather more plants than we shall need this season. We therefore offer them to those who can make a planting as late as July, at the following prices: 5 cts. for 10, 40 cts. per 100, or \$3.00 per 1000. You can have large plants or small ones, just as you choose; but if you have the large ones, the express charges will be considerably more. Small and medium sizes will be sent by mail at an expense of as much more for postage as the plants cost. We have also fine stalks of celery-plants, which we offer at the same price as the tomato.

IMPORTED QUEENS.

A couple of weeks ago we received a fresh importation of queens from our breeder in Italy. They are extra selected, and we think they are as nice a lot as we ever had. They came through in pretty good shape, and we have decided to offer them just as they come, without testing them as to their honey-gathering qualities, for \$5.00 each. The regular price has been \$6.00. The bees of all these queens, we feel almost sure, will prove to be very gentle. For some reason or other, the bees of our imported queens are the gentlest we have in the apiary. Let it be understood, that, in ordering these queens, you must not expect any thing golden yellow. The queens are leather-colored, and so are their bees. The progeny of our imported queens average, however, the best of any bees in the apiary. It generally happens that our best honey-queens are among the imported. After we have had an opportunity to grade and test our queens, we shall charge our regular prices, which will be, in July, \$6.00, \$5.00, and \$4.00.

BUSH LIMA BEANS.

This season, like the last, the bush lima beans were slow in coming up; and, worse still, a good many of them never came up at all. This was the case with the first and second plantings. To my great surprise, however, at about the third planting, only about three days later, when we had exceedingly warm, tropical weather, every bean came up as promptly as one could wish. As the first and second plantings grew so poorly I have been putting them in thicker and thicker. They now stand as thick as peas in the rows. Now, was it the hot weather that made them all germinate, or were the seeds in the bottom of the bag a little different? This can hardly be possible, because they were put through a fanning-mill and afterward hand-picked. If those who have had seed that came up badly will apply, we will fill the order again; and if others want to try the bush lima bean planted in July, (they mature as quickly as our quickest white field beans), they may have them for 25 cts. a pint or 40 cts. a quart. If wanted by mail, add 8 cts. per pint or 15 cts. per quart extra for postage.

AUTOMATIC

SELF-FEEDING

Fountain Pen

We call the attention of our readers to the Bateman fountain pen. We have for a year or two been on the lookout for a good reliable fountain pen at a price within the reach of all, and at last we have it. We have tried in our office a number of different kinds, and finally decided on one which was far ahead of all others. We bought them at a bookstore, and they were careful to withhold the name, so we could not order direct; but we have recently discovered that the pen that proved so reliable, and ahead of all others we had tried, was the "Paul E. Wert" fountain pen. This has been acknowledged by all who have tried different kinds, to be away ahead of all others. The Bateman, which we offer, was first made within the present year, and is almost an exact copy of the Paul E. Wert.

There is one little difference which is claimed to be an improvement. We have thoroughly tested them in comparison with the Wert pen, and consider them fully as good; and, what is of as much interest to you, they cost only half as much. The Wert pen usually retails for \$2.50 to \$3.00. We sell the Bateman for only \$1.25, postpaid, or you can have one free for four new subscribers to GLEANINGS, with your own renewal. A filler and directions for use accompany each pen.

The pens are 14-karat gold, with platinum point, and mounted in a black rubber holder. See cut.

✕ IMPORTED • CARNIOLANS. ✕

We have just received a very fine lot of select imported Carniolan queens. Price \$4.00 each, and guaranteed to arrive at your P. O. in good condition. We also have a very fine lot of home-bred Carniolan queens that are ready to ship by return mail. With us 90 per cent have proven to be purely mated. Some parties have condemned the Carniolans, but we are safe in saying that they have never had any pure Carniolans; so the pure Carniolans did not get justice. See what A. I. Root says in GLEANINGS, July 1st, regarding pure Carniolans. Give them a fair trial, and you will find that they have qualities superior to any other race of bees. One untested queen, \$1.00; six, \$4.50; twelve, \$8.00. For further particulars write for free circular and and price list to

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

Having a few colonies of hybrids to Italianize, we offer for sale 12 or 14 mismated queens for 50c each until sold. Some of the queens produce almost three-banded bees, and their progeny are almost pure Italians.
T. L. THOMPSON, Blairsville, Pa.

FOR SALE.—25 nice, large, laying hybrid queens at 25c each. Send at once if you want nice ones.
F. H. PETTS, Warsaw, Mo.

We have about 70 Carniolan queens (in an out-apiary) that have mated with Italian drones. We offer them at the following prices: 50c each, or \$5.00 per doz. The above queens are large and prolific, and are only one year old. Reason for selling above queens is, we are going to change to all pure Carniolans.
F. A. LOCKHART & CO.,
Pattens Mills, N. Y.

A few young hybrid queens for sale at 30c each, buyer to send provisioned cage.
JOHN GINTER, Pleasant Home, Ohio.

Hybrid queens wanted, but do not send them until you write to and hear from
O. R. COE, Windham, Greene Co., N. Y.

Hybrid queens, 30c; mismated Italian queens, 40c; all young, and very prolific.
B. DAVIDSON, Uxbridge, Ontario, Can.

HONEY COLUMN.

CITY MARKETS.

COLUMBUS.—*Honey.*—Honey scarce, and selling at 1½ for choice white clover. Twelve or fifteen hundred pounds would meet with ready sale.

July 8. EARLE CLICKINGER, Columbus, O.

CHICAGO.—*Honey.*—Market is bare of honey of all kinds, both comb and extracted. New comb will bring 13c. A little fancy has been sold at 15c. Extracted from 6@8. Weather warm but there is some demand, and consignments would sell.

July 8. R. A. BURNETT,
161 So. Water St., Chicago, Ill.

NEW YORK.—*Honey.*—New Southern strained arriving freely. Quality poor, and prices declining. We quote from 60@65c per gallon. New extracted, orange blossom, 7@7½. New California, white sage, 6@6½. California light amber, 5½@5½.

Beeswax.—Scarce and firm at 24@30.

July 7. HILDRETH BROS. & SEGELKEN,
28 & 30 West Broadway, New York.

CINCINNATI.—*Honey.*—Demand is good for new crop extracted and comb honey. Judging by present arrivals, there has been a good crop harvested. Extracted honey brings 5@8c on arrival. Comb honey 12@15 in the jobbing way, for best white. *Beeswax.*—There is a good home demand at 24@26c on arrival.

July 9. CHAS. F. MUTH & SON,
Cincinnati, O.

DETROIT.—*Honey.*—No new honey in the market, and no desirable old left; it is quoted at 10@13c. Extracted, 7@8c. *Beeswax* wanted at 27@28c.

Bell Branch, Mich., July 8. M. H. HUNT.

ST. LOUIS.—*Honey.*—Trade quiet at unchanged prices.

July 9. D. G. TUTT GROCER CO.,
St. Louis, Mo.

NEW YORK.—*Honey.*—Market is unsettled, it being now between seasons. We quote common Southern, strained, at 60@65c per gal. New California extracted, 6@6½c per lb.; new Cal. comb, 11@12. *Beeswax*, scarce, 27@28.

July 9. F. G. STROHMEYER & CO.,
New York.

BOSTON.—*Honey.*—No change in honey or beeswax.

July 9. BLAKE & RIPLEY,
57 Chatham St., Boston, Mass.

FOR SALE.—2000 lbs. very fine extracted honey; also 2000 section honey, all white clover.

G. L. JONES, Grand Ridge, Ill.

WANTED.—I shall need thirty or forty thousand lbs. of comb and extracted honey this coming fall. Give particulars as to quality, kind, and price.

J. A. BUCHANAN, Holliday's Cove, W. Va.

QUEENS from imported mother; untested, 75c; tested, \$1.25; three-frame nucleus, with queen, \$3.00. Safe arrival guaranteed.

THOMAS & KISSEL, Horatio, Darke Co., Ohio.

Yellow Carniolans.

I have a new strain of bees. They are Yellow Carniolans. Queens are large and extra prolific. Worker bees show three yellow bands; are very gentle and the best honey-gatherers. One queen mailed (safe arrival guaranteed) on receipt of one dollar. Those who are looking for a new strain of bees should try the Yellow-banded Carniolans.

16 COLONIES in 10-frame L. hive at \$3.00 each, or the lot for \$40. P. H. FELLOWS, Broadhead, Wis.

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 5 lines, and you must say you want your ad in this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. This department is intended only for bona-fide exchanges. Exchanges for cash or for price lists, or notices offering articles for sale can not be inserted under this head. For such our regular rates of 20 cts. a line will be charged, and they will be put with the regular advertisements.

WANTED.—To exchange all kinds of wall paper, for honey. 1tfdb J. S. SCOVEN, Kokomo, Ind.

WANTED.—To exchange 1 lb. of thin fdn. for 2 lbs. of wax. 7tfdb C. W. DAYTON, Bradford, Ia.

WANTED.—To exchange Italian bees in portico L. hives for a good set of tinner's tools. 13tfdb J. A. BUCKLEW, Warsaw, Ohio.

WANTED.—To exchange a 14-inch Foundation-mill, good as new, with dipping tanks and boards, for beeswax, tin plate, metal rabbits, T tins, or offers. A. A. WEAVER, Warrensburg, Mo. 13-14d

WANTED.—Second-hand foundation machine. Give description and price. J. F. MICHAEL, 13-14-15d German, O.

WANTED.—To exchange fine young Carniolan queens, for foundation, or supplies, or other offers. F. A. LOCKHART, Pattens Mills, N. Y.

WANTED.—1000 lbs. of nice white clover bees' honey, in 1-lb. sections. Will pay cash, or exchange supplies for the apiary. Address with price, A. D. ELLINGWOOD, Milan, N. H. 14-15d

WANTED.—To exchange one 1¼ in. single express harness, 1 saddle, for shogun, incubator, thorough bred poultry hand garden cultivator, or offers. A. F. AMES, Tamasoa, Perry, Co., Ill. 14d

Hurrah for the Carniolans! They take the lead; win the race; secure the prize. If you want

TONS OF HONEY,

Try the Carniolans. Hardest to winter; pleasantest to handle; best honey-gatherers. Our stock is the best that can be procured, and is bred miles away from other races.

Prices: One untested queen, \$1.00; 6 for \$5.00; 12 for \$9.00. One tested queen, \$2.50. One imported queen, \$3.50. *The Bee-Keepers' Advance* and an untested queen, for \$1.25.

J. B. MASON, Mechanic Falls, Me.

SELLING HONEY.

ANOTHER COMMISSION MAN'S EXPERIENCE; GRADING; THE PROPER SIZE OF PACKAGE; DARK HONEY NOT UNSALABLE.

IN GLEANINGS for June 15 I was surprised to see that your correspondent, Chas. F. Muth, with his experience in selling honey, advocates the use of small-size (one dozen combs) shipping-crates. We think they are 'the worst style of honey package that comes to market, and rarely see an invoice arrive in good order. They are undoubtedly intended to be sold to family trade by the case, but that is a failure; for families who seek to buy their supplies in a wholesale way, although good economists naturally, are not liberal-minded enough to accord anybody much profit. Hence their "penny wise pound foolish" way of oftentimes overstocking themselves, and thereby satiating their appetite for honey, and consequently they do not use nearly as much in a season as they would if bought along as they wanted it by the combs, affording the retailer or dispenser a small (due him) profit.

The reason this small-size packing-case is so generally out of condition is, freight handlers, express agents, etc., handle them so carelessly, pitching them about (play-ball fashion), where, if double the weight, they would not do so.

The double-deck case is a mistake, and ought never to be used. The flat and nearly square case being too wide and too much like a flagstone to handle, is not desirable.

Our experience and observation is, that the best packing-case for comb honey is a case holding from 25 to 30 combs (one tier) to be about 24 in. long and 10 in. wide, height of one comb. This size of packing-case can be loaded on the truck, and handled by one man where the square flat case can not be.

Although no honey should be trucked, freight-handlers and uninterested humanity generally take the easiest way, and it is difficult to always prevent them; hence we believe in packages that will best stand their carelessness.

Screwing on covers is a mistake, as screw-drivers are not always at hand, while jack-knives are more plentiful, and will open a nailed-on cover much quicker and safer.

Our advice is, put your comb honey up in thin $\frac{3}{4}$ -pound sections, being longer one way than the other, and to make the most show for the amount of honey. It is done in all articles of merchandise, and is due the article itself.

The best package for the honey-producer to put his extracted honey in is 60-lb. tin and 150-lb. pine fish-kegs, being the cheapest, and answering every purpose. The retailer prefers buying in bulk and selling in any amount his customers may want. The bottler and peddler prefer to buy in bulk and put up in their own peculiar or pet style of package. So much for the style of package that honey should be marketed in.

But we should be very sorry if Mr. Muth's idea about buckwheat or dark honey should prevail, for the sale of dark honey is many times greater, especially here in the East, than clover or any light honey, simply because it sells at a price that the masses can pay. Of course, if clover or any light honey could be sold at the same price as buckwheat, dark, or mixed honey, would be as much sold; but I doubt whether much more, for the masses are not connoisseurs or epicures generally, and the dark honey is heavier bodied, goes further, and generally does not have as rank a bee flavor as light honey.

Right here the thought suggests itself, that the less different names given to honey the better, for

they are confusing to those who are not up in bee culture any better than myself. All light honey is known as clover honey, and all dark or mixed honey as buckwheat honey, and that is enough, commercially. If honey goes on the market as clover, buckwheat, basswood, goldenrod, etc., and on that line finally the name of every weed and flower that a bee gets any honey from, it will cause a useless confusion in trade, and interfere with a free consumption; for when one wants to buy honey, if he can't find some certain flower, honey that some enthusiastic wise bee keeper has told him his last light honey was made from, he won't buy.

Concerning extracted honey, I think the dark honey has the advantage, for it has no season, but sells the year through for about the same price; while to get the price that light extracted honey commands, it has to be sold early before cold weather, hence its selling season is much shorter; and if kept over that season it depreciates in price more than the dark extracted honey. I have no inventions in the honey line. I am writing this only for the good of the honey trade, if there is any good in it. If a uniform style of package could be adopted, so that the much-despised middleman could depend upon receiving it so he could duplicate his orders at all times with the same style of package, the consumption of honey would increase many fold.

H. R. WRIGHT.

Albany, N. Y., June 25.

Friend W., I know you have for years been remarkably successful in disposing of dark *comb* honey; but I did not know before that you had succeeded in finding a market for dark *liquid* honey. We are very glad indeed to know it; and it illustrates once more the fact that people buy and use many things when they once get into a notion of doing so. In our vicinity they have got into a notion that honey must be white, and therefore they will not even taste of any thing else—at least a great majority of them.

SHIPPING AND SELLING HONEY ON COMMISSION.

SUGGESTIONS FROM A COMMISSION MAN.

Mr. Root:—I was induced to go into the receiving of comb honey for this market last August, by a man of wide experience in that line. Of course, he was allowed to write and solicit consignments, and all he did say on paper I do not know, as I kept no copy then of the letters as I do now. Well, on came the honey from different sources. It was very gratifying to know that the man was well known among bee-keepers, having been in business quite a while before. Just about the time the honey came in and should have been sold and put upon the market, he got into some difficulty that detained him from active work for me or us, and then the whole thing of making a new trade and a new market fell to my lot; and although not successful as to obtaining the prices the shipper wanted, owing to the bad season for honey, we managed to dispose of about 30,000 lbs. of comb honey and 60,000 of extracted honey, at prices, for comb honey, 9 to 12 cts., for dark and buckwheat; 12 to 13 for number 2 clover and basswood, and 14 to 16 for fancy No. 1 clover; paper boxes, 1 cent more, and the extracted 5½ to 7 for buckwheat, fall flower, and

dark; and 6½ to 7 for mixed and for basswood; and No. 1 white, 7 to 7½ and sometimes 8 cents. Of course, we charged 5 per cent commission on extracted and 10 per cent on comb honey; charge no interest, insurance, or storage, but merely take off the freight and cartage or expressage; and with all that we have men ship us who are not satisfied, and make all sorts of threats of what they will do about publishing us before the convention held by bee-keepers, etc., so that I will not get (they say) any one to ship to me. Now, I do want to ask you if the few men who have written me thus are a fair type of bee-men or honey-shippers. If so, I hope they will be judicious enough not to place themselves in a position to be answerable to the law for defaming the name or the man's business.

I will now give you some points in my experience that have a tendency to ruin a market on comb honey, so that it is impossible to get fair prices for it; for instance: Last fall, nearly every commission house that handles produce or vegetables had several small consignments of honey, and they sold it at what they could get for it, and especially if some of it came in a leaky condition; instead of fixing it up and getting at the actual loss and selling the rest at a price to sustain the market, they let it go at any thing to get rid of the "sticky stuff," and the sharper who bought it does what the receiver should do, and he who sells it to the consumer at so low a price that the honest handler says, "I can not get honey to sell at that, hence I am off." Now, as a remedy, every shipper of honey should write to any large city and find out whether there was or is a honey-house there, or a man who makes a specialty of handling honey in all shapes, and correspond with him about their productions, and in that way his honey goes to one party, and the wholesale trade know where headquarters for it is, or should be, and there they go to get it, good, bad, or indifferent, and prices for all kinds and styles, and much better prices could be obtained and much more satisfactory all around.

I should like to speak about a few things in regard to honey being broken in the case. We can not recover from the railroad company every time, as the companies receive it only at owner's risk of breakage; and if it comes in a leaky condition they say they are not responsible for it, unless it should be smashed in transit by a wreck, or packages broken to pieces in transit.

E. J. WALKER.

Philadelphia, Pa., March 14.

Be not weary in well doing, friend W. You know the rest of the text. Do your duty well and faithfully before the great Father above, and you will surely find your reward. Faithful, honest, conscientious commission men are always in big demand. In regard to shipping at the owner's risk, I think if I were shipping honey I should prefer a higher rate, and have it go at the railroad company's risk.

SPACING BROOD-COMBS.

IS IT 1½, 1⅞, OR 1¾?

AFTER reading GLEANINGS, pp. 490—2, where the points are so ably brought out on both sides, I would not even need to make a comment were it not that the subject is one of more than ordinary importance. I wish I could feel that I fully deserve

the compliment Bro. Doolittle pays to my style of writing; but the fact is, that, in so many things, as in the present case, I am so ignorant of just where the truth lies, that I dare not be very positive. I sometimes say, "There are a few things I know all about, but bee-keeping isn't one of them." But about that distance. I wish we could have a series of very full tests of what bees themselves would do under different spacings. I don't think I believe in following nature quite as much as Bro. Doolittle—we kill off most of our roosters, and cut out drone comb—still, when there is no special reason on the other side, nature is a pretty safe guide, and nature and Doolittle together make a strong team. I never thought of the cappings in measuring, and who but Doolittle would have thought of measuring them as he did? The question the hardest to be decided is, how much space is needed between combs to allow bees enough to get up the requisite heat in the spring? As suggested, the changing-about of frames makes more room necessary than if each comb always remained in the same place. But, say: With the Keeney method of wiring, or, perhaps better, with Hatch's plan of leaving out one diagonal, we can have the septum of the comb exactly in the middle of each frame; and then if spaced at fixed distances each comb will exactly fit wherever it is put, except where bulged with honey. That $1\frac{1}{2}$ of nature is hard to get over. But doesn't nature make allowance for corrugated combs and for drone comb? I just measured a piece of new drone brood sealed, and it was $1\frac{1}{8}$ in thickness. I didn't suppose it was so thick. Is it all so thick? For such comb $1\frac{1}{2}$ would seem close spacing.

What has now been brought out by Doolittle's article leaves the matter in somewhat clearer light, and we have these data: Sealed comb is at least one inch thick, and workers stand $\frac{3}{8}$ high on it. Allowing the workers to stand back to back makes two layers of bees $\frac{3}{8}$, making $1\frac{1}{8}$ necessary if spacing is exact and the bees just touch. But spacing is not exact, and the bees should not be allowed to rub the feathers off their backs, so it seems a little more than $1\frac{1}{8}$ is needed. Nature has $1\frac{1}{2}$, so no more than $1\frac{1}{2}$ is needed; and as that allows corrugations and drone comb, neither of which we want, we can get along with a little less. Now, Bros. Doolittle and Root, you have made the matter clear enough so that for the present I'm going to settle down on $1\frac{7}{8}$ till somebody comes along and knocks me off from it. I'm rather sorry for it, because all my plans are made for $1\frac{1}{8}$. All the same, I thank you for the light you have given.

After I had written the above I read it over at the breakfast-table, when my assistant said, in a rather vehement manner, "I don't care, I'm with Ernest; $1\frac{1}{8}$ is all right, nature or no nature. Look at the nice frames of brood we have with $1\frac{3}{8}$ spacing, filled clear to the top-bar, instead of having a big margin of honey all around." And then she took a big bite of bread to emphasize her position. I tried to make a compromise something after this fashion: "Yes, I think there is something in that, and our present spacing makes it much easier to get out the dummy. I don't suppose it makes much difference in hot weather whether the spacing is too wide or too close, so for convenience in handling we'll let the frames remain as they are; but when it comes to the last spacing of the season we'll put the dummy close to the side of the hive or

take it out altogether, and leave $1\frac{7}{8}$ through the winter and spring."

GETTING BEES STARTED IN SECTIONS.

In reply to your question, friend Root, on page 493, I may have had bees "that cram the brood-nest and leave the sections untouched," but I have not observed it. If you ever again find such a colony, try it with a good bait section; and if they leave it untouched, please report it. I think the very best bait is a section partly filled, taken bees and all from a hive where the bees are at work in the super. That idea I got from you, but ordinarily the empty comb answers every purpose.

BEES FILLING OLD SECTIONS.

By the way, I've watched pretty closely about the bees finishing these baits; and although up to July 3d no sections are entirely finished, the sealing is in all cases more advanced on the baits; and if I ever find a case in which the empty foundation is finished before the bait, I promise to report it. You can now go to super after super, and find sealing commenced on the bait, but on no other section.

Marengo, Ill., July 3.

C. C. MILLER.

Very likely, friend M., you have no trouble with bees that won't work in sections, so long as you make it your invariable custom to use the baits; and right here is a pretty good hint for some of the rest of us.

THE DIAMOND RATTLESNAKE.

PROF. COOK IS HAPPY IN THE POSSESSION OF A LOT OF POISONOUS RATTLESNAKES.

Dear Friend Root:—I wish I could invite all the readers of GLEANINGS into my laboratory and show them our beautiful rattlesnake. It comes from Mr. S. A. Preston, Burnet, Texas; and considering its long journey it is very agile and sprightly. It is very handsome. The colors are a rich brown, and the light diamond-shaped spots on the back are very beautiful. He brought his rattle-box all the way from Texas with him, but refuses to shake it either for his own or others' amusement (?). Perhaps he mourns for the (?) he left behind him, and so he has no heart for amusement. His appetite also seems to be wanting, for he refuses to eat even frogs, with the delicate hind legs that are so coveted by epicures. Possibly he will break his fast after a night's rest.

And just now a telephone dispatch says I have another rattlesnake at the express office, from W. H. Rempfer, Swales, Pa. I shall have him in the cage with the other very soon. We shall be glad to learn how the rattlers of Texas and Pennsylvania take to each other. Heigh-ho! Another reader of GLEANINGS from Louisiana sends a third rattlesnake. I shall put them all in the box together, and will report later to the readers of GLEANINGS how they behave. I can give a very interesting paper on these terrible reptiles, which I will do for your readers as soon as I have had a chance to become better acquainted with these new arrivals. Now for a good large live copperhead and moccasin. Who will send them? I want the finest cage of poisonous snakes in America. Thanks to GLEANINGS and its readers for the prospect.

THE HELMGRAMMITE.

Mr. C. F. Thomas wishes me to report on a large lace-wing which he has sent to me. The lowest order of insects is the neuroptera, or lace-wings.

They are so called because of the numerous veins and cross-veins to their wings. Thus their wings resemble gauze or lace. I hardly need say that the dragon flies, or darning-needles—the bee-hawks of the South—and the day-flies, which often gather about the street-lamps in our lake cities, like Toledo and Cleveland, belong to this great order. Many of these insects, while larvæ, live in the water and feed on the small aquatic animals that keep them company in their watery homes. Nearly all lace-wings are predaceous, and feed wholly on other insects, and so are to be classed among our beneficial insects.

The hellgrammite (*corydalis cornutus*) is our largest lace-wing. It is four inches long and six inches from tip to tip of wings when they are expanded. The specific name, *cornutus*, comes from the jaws, which are developed into two long horn-like organs which strongly remind one of the tusks of the elephant. The larvæ is a long flat insect, with strong jaws, and lives in the water. We often catch them in the Cedar River, which flows through our college farm. The insect pupates under some board or stone at the water's edge. I do not know the origin of the common name, hellgrammite, but think the alarming appearance of the fly and the larvæ might have suggested it. Terrible as the insect looks, it is entirely harmless, and no one need fear it in the least.

ANOTHER HERMAPHRODITE.

Mr. Timpe has sent me another hermaphrodite. This one is really a drone, as it has the male organs. Its head is really drone, though the antennæ, in number of joints, are like those of the worker. The legs on one side are like those of the drone, while those on the other are like those of the worker. As I understand, this bee is from the same queen as the other one sent a few days since. I think this is a very interesting matter. I believe there are some very interesting scientific inquiries that these hermaphrodites may answer. I should take it as a great favor if any bee-keeper who may discover such bees would send them to me. I wish to make a thorough study of the whole question.

Agricultural College, Mich., July 2. A. J. COOK.

EDITORS ANSWERING QUESTIONS, &c.

UNNECESSARY AND FOOLISH QUESTIONS.

THE more care I devote to the perusal of your papers (A B C and GLEANINGS), the more I feel convinced that my last letter was even *too* weak in regard to the honor due you as a writer and editor. Your way of writing is exactly what most bee-keepers need—plain, yet solid information—saying much in few words. Oh how it amuses me to find, from time to time, that some are questioning you on subjects which you have so clearly answered long ago. Good heavens! what patience an editor must have! This reminds me of something that happened at our late State Farmers' Institute, at Chrisney, Ind., last February. I was asked to give a lecture on the farmer's home. It was very well received. The second day, a professor of Perdue University had a very instructive lecture on crop rotation. He spoke exceedingly well, with a voice clear and well adapted to the locality. After the lecture was given, the gentleman asked if any one among the audience would like to ask some questions. A bright-looking man arose and asked, "Do I under-

stand the speaker to say that we should plant wheat every year on the same piece of ground?" Holy Moses! I could have kicked myself. I said to myself, "If my lecture of last evening, on the farmer's home, was as well understood as the lecture of Prof. N. N. on crop rotation, then God help us."

When—yes, when—will our people begin to study and think just a little more than they do? Again and again you are asked how bees should be handled; how the frames must be spaced; how to secure a good crop of honey, etc. Does it not require more than ordinary meekness to stand all this? I can only admire men who possess such virtue and act accordingly.

THE HEAVY TOP-BAR A GOOD THING.

It gives me a great deal of satisfaction to find that a heavy top-bar frame is asked for by the fraternity. I have used them since 1883; also a friend of mine, Mr. J. B. Mueller, principal teacher at Ferdinand, Ind., has used them since that time. We used them alternately—one with a deep top-bar and the next one a Simplicity frame with metal corners. Sections can be placed on thick top-bar frames without any sagging whatever. Bees will place less wax on top of these frames, even if no quilt is used for a time. Yet I fear that all will not hold good for what certain writers claim for them. Combs rest firmer in these frames, and wire is not needed to keep the foundation in shape, or to keep comb from breaking. Such frames are more durable and more stable, if placed in the hive. But an active queen will get upstairs and have things all her own way, as you say, in spite of these thick-topped frames. Even to a third story will her majesty ascend, and see that all her subjects are doing their work. This is our experience. By all means, staples should rest in either end of the frame, else the proprietor will kill more bees than in handling the thin-top-bar frame. This is not paying to any one unless he cares to possess a good many stingless bees besides the dead ones.

A DOUBLE-WALLED SIMPLICITY.

I should like to draw your attention to a double-sided Simplicity hive. Make a second hive that will exactly cover the Simplicity hive, allowing only tar-paper space. Nail or screw together, and you have a hive next to a chaff hive. I consider this the best hive, in very cold as well as in very hot weather. I have the idea of this hive from one my father, Hon. J. C. Stenger, used for 28 years. In all these many years this same hive stands on a limestone rock, and never have the bees suffered in this hive. They swarm less from that hive; and in regard to comb honey, it has been the "boss" for 28 years. These, certainly, are convincing facts in favor of a double-walled Simplicity hive. Give your opinion on this subject.

THE TOBACCO DEVIL MORE HARM THAN KING ALCOHOL.

In conclusion, I say this much to you: That in fighting the tobacco devil you have a friend and helper in the writer of these lines. Tobacco does even *more* harm than the heavy drinks, and they do harm enough in this world of ours.

[REV.] STEPHEN STENGER.

St. Meinrads, Ind., June 24, 1890.

Thanks, friend S., for your kind words. But we do not have very many foolish questions—certainly none as bad as the one you mention. It does, however, sometimes seem positively awful to find how people

will get hold of things when one is trying hard to make them plain. Notwithstanding, let us not discourage people from asking questions—let them come. Hives made double walled, with tarred paper between, have been a long while in use. Our experience is, that they do not dry out as well as the chaff hive; that is, they are more likely to be damp and moldy inside during a spell of damp weather.

—◆◆◆— TAKING QUEEN-CELLS AWAY FROM THE BEES, ETC.

DOES SHAKING COMBS INJURE THE EMBRYO QUEEN ?

A correspondent wishes to know "if it will answer to shake the bees off the frame of brood having queen-cells upon it, if it is wished to save the cells for use." No—not by any means. Very many have been the number of queens killed or injured for all time by this plan of getting the bees off the cells. If the cells are only just capped over, such shaking dislodges the royal larva from the royal jelly, throwing the larva to the bottom with such force that it is either killed outright, or, in failing to get back, dies where it is. If further advanced, such shaking deforms the queen by her having crippled wings or legs, or, what is more often the case, the queen has a dent in the abdomen, certain segments of which are dented inward or the whole flattened or curved. While this last is not as bad as to have the wings deformed, yet it is a very rare case where a queen with a deformed abdomen proves to be a really good queen. Such queens generally become fertile and lay quite well for a time, so are of some value; but those whose wings are crippled are worse than no queen at all, for they can never become fertile, while they stand in the way of our successfully introducing a laying queen. In case such crippled-wing queens are of the German or hybrid race, they are very hard to find, and the parties who have ordered queens for supposed queenless colonies having such crippled queens, and lost them in trying to introduce them, can be numbered by the score, if not by the hundreds. No one should attempt to introduce a queen to any colony, unless he takes away the reigning queen at the time he puts in the new one, without first trying the colony with unsealed brood to see if they are really queenless. If they build queen-cells on this brood he can know that they have no queen; if not, then he may know that, if he tried to introduce a queen to that hive without first finding and taking out that which the bees are reverencing as a queen, he will be certain of losing the one he would have preside over the hive. But, to return: How shall we get the bees off the queen-cells if we can not shake them? The way I manage is as follows: Upon removing the frame of cells from the hive it is carefully set down at the entrance of the hive, the same side up that it occupied while in the hive, and the bees on it thoroughly smoked so as to cause them to fill themselves with honey while the hive is being closed, when smoke is again poured upon them to such an extent that the most of the bees will run into the hive, when the remainder are brushed off with one of the bee-brushes which can be had of A. I. Root. If they are loth to run off the comb into the hive, the whole can be brushed off; but be sure that

they have filled themselves with honey before you undertake to brush off so many bees, unless you are willing to stand many stings, for the bees around queen-cells will fight with a vengeance for them, unless the precaution is taken to coax them to fill themselves with honey. If the weather is cool and the cells are to be placed at once in the hives, it is a good plan to take the bees along with the cells so as to keep the cells warm, when, with a little smoke, drive the bees off the cell you wish, so that they will be out of the way while you take it off the comb. After the cells are all off, then the bees can be shaken off the comb at the entrance of the hive, the same as from any other frame. This latter way of not trying to get the bees off till after the cells are, is good at any time where the cells are to be placed in different hives about the apiary.

STORES FOR WINTER.

As the basswood will be yielding honey in most localities by the time this reaches the readers of GLEANINGS, I think it will not be amiss to tell of a good plan of securing good stores for the bees to winter on. I know many will say, feed sugar syrup, but it is quite a job to feed a whole apiary with liquid feed at a time when robbers are always plentiful; besides, at the present high prices of sugar there is little if any profit in it. Good basswood honey is good enough for winter stores, and the advocates of the pollen theory can not object, for there is no pollen ever gathered from the basswood bloom. The plan is this: When honey commences to come in from basswood, four or five nice worker combs are placed in the upper story of the hive which we are running for extracted honey, and on the top-bars of each of these are placed the letters W. S., which signifies winter stores. These combs are to be placed about 1½ inches apart from center to center, and are not to be extracted from at all. As soon as the honey in these combs is sealed about two-thirds of the way down, they are to be spread apart, and other combs or frames filled with foundation placed between them in each alternate space, or enough to fill out the hive. These last are to be extracted from; but the former are to be let alone to the end of the season, when we have all the stores the colony needs, well ripened and of the finest quality. In preparing the colony for winter, place three or four of the frames of honey next one side of the hive, then place in one of the frames with the bees on it which has very little honey in it; next, the last comb of honey, and finally two more combs with the bees on them, when the hive is to be closed and the bees from the remaining frames that were formerly in the hive shaken off at the entrance. This is done so that the bees shall cluster at one side of the hive early in the winter, rather than in the center; for when in the center they frequently eat all of the honey toward one side of the hive; and if this happens in very cold weather they starve there, not being able to cross over to the other side. With the above plan they are all right as long as there is any honey in the hive.

G. M. DOOLITTLE.

Borodino, N. Y., July 7.

Friend D., I fear you are a little too emphatic in regard to what you say about shaking combs. It was suggested, years ago, to purposely save cells from combs that had been put into the extractor, and we did not find an imperfect queen as the result. They may, however, have been at such a

stage that they were not easily injured. At other times I have been troubled because of the number of queens with bad wings and crooked or indented bodies, and I should not be surprised if your remarks point out and explain some of these cases. I fear that many of our friends will object to using basswood honey for winter stores.

ANOTHER HIVING ARRANGEMENT.

O. R. COE'S METHOD.

Friend Root:—The method of hiving swarms that I have used for a few years is so simple that perhaps it might be best to have it described in GLEANINGS. I have a hiving-box made as follows: A square box, 12×12 inches, and 12 deep, with half of the front side cut away. For bottom I nail on a board 12×18, which extends out 6 inches in front; and for a cover a plain board in which I bore several half-inch holes and put in sticks 4 to 6 inches long, which extend down into the box on which the bees cluster. Fig. 3 shows the inverted cover with the sticks, and Fig. 2 the hiving-box complete, with cover on. The handle of the box is a small iron rod to which I have attached a few feet of small rope.

COE'S HIVING APPARATUS.

When a swarm comes out I wait until they just begin to cluster on a limb when I place a ladder near them. I then take the hiving-box and hold it in the hollow of my bended arm. I now tip the box forward until the bottom-board of the box stands at an angle of 45 degrees, and with the other hand I shake the cluster of bees down into the box, and they at once go up and cluster in the box. I now throw the rope over a round of my ladder or a limb of the tree near the ground, and leave it suspended. With my smoker I prevent any more bees clustering on the limb from which they were first shaken into the box, and in a few moments they are all quiet in the box.

I next prepare their hive, and always place an empty half-story under it, as in Fig. 1. A yard square of enamel cloth nailed to two pieces of boards 1½ wide, I spread in front of the hive. I now take the cover from my hiving-box with nearly all of the bees hanging to it, and the sticks, and shake the bees on to the enamel cloth; and if there are many bees yet on the sides of the box I turn it

over and shake them on the enamel cloth also; then grasp the ends of the sticks of the enameled cloth, and, as you lift the bees up, they will slide down toward the center as it bags down, and then I hold it so that they slide down into the half-story hive. I now slide the hive forward. But few bees will fly, and the swarm is hived very quickly.

SOME OF ITS ADVANTAGES.

The great point is, that I can get them into the box as quickly as they would settle on to a limb or on to a Manum swarming device, and then, to all intents and purposes to the bees, they are hived. I can place a dozen swarms (if I have so many hiving-boxes) on the stands they are to occupy, and they will fly from and to the box, and mark their new location as well before as after they are placed in the hive. This is a great point with me when I have many swarms. I never had a swarm leave the hiving-box after it was once in it all right, until I shook them out. The enamel cloth fastened to sticks is a grand thing to use in transferring and many other uses, as bees can be shaken on to it and slid off where we want them.

O. R. COE.

Windham, N. Y., May, 1890.

GLEANINGS FOR JULY 1ST.

SOME OF ITS CONTRIBUTORS.

Friends Root:—(You see I want to include Ernest in my greeting, for we have learned to appreciate the practical things from his pen as well as the good things from A. I.'s). I have just left off devouring No. 13 of GLEANINGS after having read every thing in it from cover to cover, including most of the advertisements, and now I propose doing what, many times in the past year, I have felt like doing, but never did; i. e., give you both my heartfelt thanks for the bi-monthly feast of good things that GLEANINGS never fails in bringing us. I need not say, "God bless you," for it is evident to all the 10,002 subscribers, and the additional host of readers of GLEANINGS, that he is constantly doing that. Let me say, rather, may God's blessing *continue* with you in all your future as you now enjoy it; and I will add, that I believe it will so long as you keep his colors nailed to the mast, and your one hand placed in his while the other holds the helm. And while I give thanks to yourself and Ernest, I want a good big share to go out through GLEANINGS to Dr. Miller, Mr. Doolittle, Prof. Cook, Mr. Manum, Mr. Hasty, Rambler, Mr. Heddon, and the many other veterans who so ably and interestingly discuss all pertaining to the apiary.

BLACK BEES GENTLE.

A little more than a year ago I knew next to nothing of one of God's most wonderful creatures, and scarcely ever gave the honey-bees credit for the delightful sweet I had so often enjoyed. But now, thanks to you all, and to the Father's hand that guides our steps, and led me to invest in a few colonies of bees, I have had the veil removed; and while I still stand enraptured on the threshold, and feel that I have but entered on a pursuit that promises exquisite pleasure, I have already enjoyed so much in the investigation of my interesting little friends that I am already a thousand times repaid for the score or so of stings I have received. It appears to me I must have secured an exceedingly gentle lot of bees. I have ten colonies. They are the common black bees, with possibly a

very slight admixture of Italian, and yet I can open any of them, handle as I desire, and when I please, and change from one hive to another, and brush out remaining bees without any such "lively fracas" as you had with your cross hybrids. In fact, the nearest approach to any such circus I have experienced was with pure Italians, in the apiary of the Misses Barnes, at Piketon. A short time since I made them a business call, and while in the apiary with a hastily improvised veil over my hat the wind blew it off, and in less time than I can tell it a dozen or more little warriors took a mean advantage of the situation and attacked me from behind, and with drawn spears they began prodding me so vigorously in the back of the head that I, like you, made an inglorious retreat; nor did the little rascals stop with "a field fairly won," but followed in very hot pursuit after I had crossed the fence, and until I entered the invitingly open door of an out-building some rods distant. But, thanks to a highly appreciated constitutional condition, the dozen or so stings received did not inconvenience me any worth mentioning.

I don't know that any thing I have to say will be of interest or profit to the gleaners of GLEANINGS; but feeling assured that you have a capacious waste-basket I can not forbear giving an item or two of

MY EXPERIENCE.

First, after nearly killing two colonies with the smoker while transferring from box hives, I discover I don't need any smoker at all to handle bees—at least, such as I have at present.

Second, I have learned that, even in fruit bloom, if weather be cold and wet, bees can not, without stores, keep from starving. I paid one colony and very nearly two, for this information, but offer it to my brother-amateurs free of charge.

Third, I have learned not to set frames of brood in the sun while searching others for the queen. I paid the greater part of a nice frame of brood and some bees for this practical knowledge; and if other amateurs don't say, "The fool ought to have known better than that," I will not charge them a cent for this bit of experience either.

Fourth, I have learned that it is not safe to lay a caged queen on the ground. The ants are liable to kill her inside of ten minutes. I paid a nice prolific black queen to learn this, and feel thankful it was not a more valuable one.

Fifth, I have learned a much more simple and easy way to introduce queens with the Peet cage than by fastening to the comb, as per printed directions. Just lay the cage on a board with the tin cover down; withdraw the tin and put it on from the other end. Now draw it back so as to expose about a quarter of an inch of the candy; lay it on the frames with the wire side down, giving the bees access to the candy, and the work is done. By the time they get the candy eaten out they are ready to accept the queen. I have introduced five in this way, successfully.

Sixth, I am half persuaded to believe I have learned a mechanical reason for the queen laying drone and worker eggs, and that she does not control it at all. But since amateurs always get to know so much more than the oldest veterans, and so much that, by practical experience, they are forced to unlearn, I will not give this crude idea to the public until I have proved it beyond question. If some day I succeed in getting workers reared in

drone-cells you will hear further from me on the subject. If not, then you will not learn of my folly.

QUESTIONS.

Now for a thing or two I have not learned, but which I should like to know. Why does a large prime swarm, with a fine prolific queen, start a queen-cell within a week after being hived, and before the frames are more than half filled with comb? I have such a case. Is it phenomenal?

Has any one ever noticed a queen deposit an egg in a queen-cell, or is there any indisputable proof that she ever does so?

And now I must tempt the maw of that capacious waste-basket a little further, and have my little say on that very interesting case of Jones vs. Brown. With all deference to Mr. Caldwell's legal acumen, I wish to modestly protest against his assuming that, during time of contract, Brown and Jones are alike owners of the bees. Now, if I understand the case, Brown, neither by the contract nor otherwise, gained any proprietary interest in the bees. Jones was as much the sole owner under the contract as before the contract. But, like landlord and tenant, he had intrusted his property into the hands of another, under certain conditions. As in the case of a professed tailor spoiling cloth intrusted to him to make a garment of, he is liable for damages to the full extent of the loss, so a professed apiarist should be liable for loss arising from want of skill or gross negligence, clearly proven, but no further. Let us vary the case, and suppose Jones was the owner of an extensive bee-hive factory in Johnstown, Pa., prior to the flood. He enters into a contract with Brown to take charge of the plant, on condition that Brown's labor, as manager, should balance Jones' capital invested in the plant, and that they were to bear all expenses of manufacturing equally, and divide the profits. The flood sweeps the factory out of existence. Can Jones hold Brown liable for the loss he sustains from a cause in no wise attributable to Brown's want of skill or negligence as manager? We think not. If the bees had been swept away by a cyclone within an hour after Brown took charge, would any sane man hold him liable to Jones for the loss? Would it in any wise alter the case if the cyclone made the havoc one or two years after Brown took charge? or if the cyclone was one of unforeseen and unavoidable disease? It seems clear to my mind, that, if the loss was by reason of want of assumed skill or negligence on the part of Brown, he should bear all the consequences; otherwise it is Jones's loss.

Wheetersburg, O., July 7.

J. M. BROWN.

Friend B., your bees are gentle because they are getting honey. Wait until the honey-flow stops, and then see if you can handle them without smoke. I do know that bees are many times smoked most unmercifully when there is not the least reason in the world why they should be smoked at all. Your hints and experience are valuable. Most of the veterans have learned as you have learned; but you will probably save a good many beginners from loss. Your plan of introducing by the Peet cage usually answers as well as any; but where the queen is feeble, I should prefer to have her directly on the brood-comb. I think the ground has been gone over pretty fully in regard to why a queen lays drone and

worker eggs. Large prime swarms do not, as a general rule, start queen-cells within a week. I am inclined to think the queen of that colony will be superseded before a great while. Yes, a queen has been seen depositing an egg in a queen-cell.—The discussion in regard to Jones and Brown emphasizes the fact that partnerships, or bees on shares, seem to be, at the best, complicated and unnecessary. Better buy or sell outright.

**SOME GLIMPSES OF THE HOME OF
T. B. TERRY, HUDSON, OHIO.**

LAWN, GRAVEL WALKS, EVERGREENS, ETC., IN THE
FRONT, AND THE LUSCIOUS STRAWBERRIES
IN THE REAR.

IN our last I promised you some pictures of friend Terry's home, and I am glad to see that our artist has succeeded so well.

When I asked him what he did to the evergreens to make them so even and regular, and of such bright luxuriant growth, he replied that he did nothing at all. They are the ordinary arbor-vitæ. For a while I was a good deal puzzled to know why they did not look as our evergreens do, and a good many others'—one small, indifferent tree, and then another large one, and so on. The secret of it is, the ground was under-drained, enriched by thorough tilth and clover before the trees were put out. In fact, all the ground around friend Terry's home has been worked up to a degree of fertility and evenness of texture that makes all the plants and trees just alike. If the arbor-vitæ grows of its own accord of the beautiful shape of those about friend Terry's home, I should never think of bringing them into artificial shape with shears and trimmers.

HOME OF T. B. TERRY.

The graveled walk, the shrubbery, and vines by the porch tell their own story; and a row of evergreens on the right and on the left called forth exclamations of surprise from me on account of their regular appearance and beautiful shape. The house, it should be remembered, is on the north side of a street running east and west. These rows of evergreens, therefore, run north and south; and there is another row, seen in the strawberry picture, just across the back end of the dooryard, thus making an inclosure.

Having now viewed the front, the reader will please go with me up the gravel walk. We will turn off to the right, near the corner of the inclosure. Right here is the out-building that friend Terry has several times described in our agricultural papers. It is such a beautiful, secluded spot, overshadowed by the evergreens and other trees, that a picture of it is given in one of our rural papers as a hint to farmers in the way of comfort and convenience to their wives and grown-up daughters, to say nothing of the younger ones. As we step through the ever-

greens we come into the half-acre of strawberries. And here is a picture of what you see. This picture was taken from a hill, or gentle elevation, north of the house. Many of the strawberries were in blossom at the time it was taken. If you put on your specs you can get a glimpse of the blossoms here and there.

Between the evergreens and strawberries is a roadway. At the left of the roadway, and right back of the house, is the new half-acre of strawberries for the next season.

lings. As the Sterling is imperfect, a row of Downings comes next as a fertilizer. Then we have Cumberland, Gandy, Bubach, Haverland, Jessie, and perhaps some others. They are alternate, so as to have one row of perfect after every two, or, at the furthest, three, rows of imperfect. The straw mulching is plainly visible in the paths; but the cut straw between the plants can not be seen except by moving the foliage aside; but in the whole patch there is no ground visible—nothing that can soil the berries. Dur-

TERRY'S HALF-ACRE OF STRAWBERRIES.

These were planted in rows four feet apart, and plants two feet apart in the row, as I have explained. On the other side of the roadway is the wonderful half-acre which I recently visited while it was in full bearing. There are fourteen rows of berries, as you will see by the picture. Perhaps an expert could tell the varieties by the foliage. Next to the potato-field, on the left, there are three rows of some variety, the name of which I can not now remember; then come three rows that I am pretty sure, by their looks in the picture, are Ster-

ling picking time the straw is tramped down in the paths much flatter than what it appears in the picture; and one of the worst troubles, if it *was* a trouble, was the long stems of the Haverlands thrusting themselves right square in the paths in order to get sunshine to ripen. I believe friend Terry proposes to make the paths, especially through the Haverlands, a little more than a foot wide hereafter. Over in the field beyond the fence we saw the wonderful crops of wheat—35 or 40 bushels to the acre, right straight through the field. There are no

trees on Terry's premises, except around the house. He does not tolerate a tree in his grain-fields at all.

PLAN FOR APIARIES.

A UNIQUE WAY OF ARRANGING 80 HIVES.

Friend Ernest:—I was very much interested in the article by C. A. Hatch, and your own following, page 374, May 15, as I have given this subject considerable thought of late; and seeing that suggestions on this are acceptable, I venture to offer mine; but I shall not be offended, and order you to stop sending GLEANINGS, if it never appears there-in.

plan of my theoretical ideal apiary. You will take notice that an apiary managed on this plan, containing 4 groups each way (16 groups), 5 in a group, would contain 80 hives—just about the proper number, and need not occupy a plot of ground to exceed 60 feet square, and still leave ample room.

In regard to bees going to the wrong hive, I should say that those at B would know their hive was the center one, C the left, A the right of the three facing one way; those at E and D would not be at all likely to mistake another hive in the same group (see diagram), and they would not be any more liable to go to the wrong group than they would if arranged on the hexagonal or Mr. Hatch's plan. You will notice that, when the grass in the

Our apiary is arranged hexagonally, and we are pleased with it in nearly every way; but when it comes to running a lawn-mower through it, I always wish it were arranged on a plan that would admit of running the mower parallel with the hives both ways. I have also noted what the senior editor has to say on the subject. Of course, we can have our hives in straight rows, and still be on the hexagonal plan, and that is just how ours is arranged; but we are bound to run the mower diagonally one or two ways in order to cut the grass between the hives in the rows. I herewith submit a

main alleys is cut, the lawn-mower can be run between the hives in a group, though the distance from A to B should be some greater than I have allowed, in order to allow a large-sized mower to pass E without varying from a straight line. E could be set out so as to be on a line with A inside, but this would throw it out of line on the outside, unless the hives are square. Hives E and D would have their entrances at right angles to the alley for the operator, and he might be in the way of some of the bees from said colonies, but not more so than if arranged other-

wise, and we can not expect to have it so arranged as not to be in their line of flight more or less at times, as they sometimes come out and turn short around the hive before rising higher than a man's head.

SHADE FOR HIVES.

Allow me to say, that the longer I keep bees the less use I have for shade over them. First we planted grapevines, and they did not make a growth to suit me, and I concluded it would be altogether too much labor to keep them nicely trellised and tied up, so I cut them off, and now some of them seem to want to make a nice growth. I next planted seedling peach-trees, intending to bud when they got larger, and these, too, seem to want more fussing with than seedlings that volunteer to come up among grass and weeds. However, there is an elm, a honey-locust, and a cedar tree in the apiary which we left when preparing the grounds. Now, during the cool rainy spell we have been having for some weeks up to within a few days ago, the bees in the hives exposed to the sun would soon come out and get to work when he deigned to shine a few hours; while those in the shade would not get warmed enough to bring them out of the hives. I don't believe I care much whether those peach-trees grow or not. White clover is immense, as well as alsike and common red, and the bees are booming.

S. E. MILLER.

Bluffton, Mo., May 24.

I have been trying to find some fault with your plan, but I give it up. The more I examine into it, the more I am convinced that it is a good one, where economy of space and lawn-mower convenience is desirable. Whether better than Mr. Hatch's, I can not say. Instead of making each group 8 feet or more apart, as you have marked in your diagram, I would have them about twice that. Then I would have the hives 18 inches apart, so as to give plenty of room for a lawn-mower. Where hives are in groups 6 inches apart, long timothy grass will grow up, as we find by experience, and interfere greatly with the operations over the hives. Of course, you can cut it out after a fashion; but as neither lawn-mower nor sickle would be available, it will be necessary to hack it down with a case-knife, cutting a few spears of grass at a time. Well, then, if the groups are 16 feet apart, and each hive in the group is about 18 inches apart, an apiary of 80 colonies may cover about 70 feet square, if L. hives are used. It could be very easily accommodated in the back yard of an ordinary half-acre town lot, with a frontage of, say, 80 feet. With this arrangement of distances, a bee from the entrance at A, say, would have to go 40 feet to the east to find an entrance just like the one to which he belonged; and yet this entrance would be considerably different, after all. The entrance of A is near the west corner of the apiary; and an entrance similarly situated, and 40 feet east, is a little more remote from the opposite corner. Taking it all in all it is hardly possible that a bee *could* make a mistake. Of course, an apiary on this plan might not occupy more than 40 feet square, if the colonies are crowded a little closer together. But space usually is not as valuable as that. Aside from this, it is well ar-

ranged for a lawn-mower. I hope that all who can will give it a test at as early a date as possible. In actual practice there may be some serious objections to it. You will observe that it is friend Hatch's plan, as described on page 374, carried out a little more elaborately.

ERNEST.

THE BLUE AND GREEN APHIS.

SOMETHING ABOUT PLANT-LICE IN GENERAL; KEROSENE EMULSION AS A REMEDY.

There is a little green louse, or parasite, destroying my apple and plum trees. I send you one dollar to send me something to spray them with. Please send me whatever you know will fix them. What do you spray them with, and how prepared?

Dell, Ore., June 12.

G. J. GRAY.

On receipt of the above we wrote our friend that we did not know any thing that would destroy the insects that were injurious to his trees. We wrote him that we had tried in vain to destroy them on our cabbages, but gave it up. Whenever the emulsion was applied with sufficient thoroughness to destroy the insects it injured the cabbages so much that they did not amount to anything. That has been my experience for two or three years. Perhaps I should remark that relief came to us in our cabbage-raising, in the shape of a little insect, or bug, looking something like the larva of a potato-beetle. We forwarded samples of these to Prof. Cook, asking him to tell us about our unknown friends. Our readers will notice that he replies to both matters at once:

Friend Root:—I am surprised that you say that the kerosene emulsion will not kill the "blue plant lice" of the cabbage. I have believed, as the result of many trials, that it would, if used thoroughly, kill any plant-lice. To even suggest that those at the "Home of the Honey-bees" are not thorough, would be unpardonable: so you see we are in a dilemma. But, did you apply it with a force-pump so that you surely brought the liquid in contact with every louse on the plants? If so, and the lice were not killed, then you have tougher lice in Ohio than we have in Michigan. Please make the emulsion as I recommend in Bulletin 58, and apply with a force-pump very thoroughly, and write me the results.

Anent this subject of plant-lice, let me say that if G. J. Gray, Dell, Oregon, will thoroughly spray his trees with the kerosene emulsion, he will surely destroy his enemies. I have often done this, and have recommended it to others who have used it with entire satisfaction, and have thanked me heartily for the suggestion. It is specially desirable in case of young trees or nursery stock, to destroy the insects, unless, as is often the case, their natural enemies do it for us.

And this leads me to speak of the little helpers that have come to your aid in rescuing your cabbages from destruction. Of course, friend Root, you know the little lady-bird beetles "when to manhood grown," though you do not know the babies. The two insects you sent were the grubs or larvæ (Fig. 1) of one of our common lady-bird beetles. The grub, or larva, is elongated, much like the potato-beetle, only more so, is black, mark-

ed with orange or yellow, and is found very common

at this season on plants in company with ants and plant-lice. The ants are there to sip up the nectar from the lice, the lady-bird beetles to take lice, nectar, and all. Both the grubs and the mature beetles feed extensively on the lice, and thus prevail mightily against this small but terrible pest. When the box arrived, one of the grubs had assumed the mature form. I hope you did or will box one or two, feed them liberally with lice, and thus get a better introduction than any description can give you; for you may well say, "I wish to give them a hearty thank-you."

Some of these beetles—indeed, nearly all—are yellow or orange (Fig. 1), spotted with black; hence such significant names as *maculata*, *9-notata*, *12-punctata*, etc. Others (Fig. 2) are plain yellow on the wing-covers, while one small species, very common here and very useful, is black, with two orange spots, one on each wing-cover (Fig. 3). All are short and

broad, or rounded, in outline. Fig. 1 shows the larva, pupa, and imago, or mature beetle. As will be seen, the pupa is very small compared to the larva and beetle. This is true of all the lady-birds. The short lines beside the figures give the true size. Hardly a day passes that I do not see these insects feasting on plant-lice. They eat as though they greatly relished the food. I almost fancy that I can hear them smack their lips as they suck dry the fat, full-fed lice.

You may well feel to thank these and thousands of other insects that work in a similar way for us, asking no wages, and truly boarding themselves. Without these helpers, our injurious insects would prevail. Agriculture would be a hopeless industry, and our earth soon a desert waste. How wonderful is this balance in nature! Everywhere there is a limit set to accomplishment; everywhere the "fittest succeed." Everywhere success comes only with struggle and effort. How can any one study in this grand book of nature, without becoming charmed with the grand scheme of creation, and reverent as he contemplates the great Planner? Though his "ways are past finding out," we see enough to thrill us with admiration and love.

A. J. COOK.

Agricultural College, Mich., July 2.

Friend C., I really beg pardon. I knew the lady bug, as we call it, but I did not recognize the larva. As the blue aphid has entirely disappeared from our cabbages, I presume it has come about through the agency of these insects. A couple of years ago we tried every thing for the blue aphid on our cabbages and turnips that has been recommended through the papers. Some of the remedies disturbed them a little if we took pains enough; but even then, the remedy injured the cabbage more or less; and even if it had been a perfect cure, the time spent and the cost of the material amounted to somewhat more than the value of the cabbages. Perhaps a little instruction in the matter might help us to do better.

HIVE-COVERS.

AFICULTURAL NOMENCLATURE.

I SHOULD like to add my experience to the hive-cover controversy. My hives are a simple box nailed together to hold the frames, cleated at the ends. Covers and bottoms are alike—simply a plain board cleated at the ends similar to Dr. Miller's, only the cleats are made of $1\frac{1}{4}$ -in. stuff, and rabbeted $\frac{1}{2} \times \frac{1}{2}$ in., and nailed both ways—that is, through the cleat into the end of cover and through the cover into the cleat. I have used such hives and covers for about 12 years, and I am well pleased with them. I paint both sides of covers and bottoms. The cause of a cover warping is the swelling of the under side from absorption of moisture and the shrinking of the top through evaporation. Painting does away with a good deal of this, and the rabbeted cleat the remainder.

I was much interested in Dr. Miller's article on the above caption; but your answer to the question, "What is an apiary?" though it may be good Webster, does not seem to me to cover the ground, or, rather, it covers too much ground. If an apiary is a place where bees are kept, then what is an apiarian? A man who takes care of a place where bees are kept? Again, we often hear the expression, "Moving an apiary." Now, we can not move the place where bees are kept unless they are kept in a house and the house is moved. And in connection with this I should like to call attention to the fact that the names of some of our forest-trees that produce honey are often misquoted. For instance, the poplar is often called by the names of "whitewood," "tulip-tree," etc., and you, Mr. Editor, seem to think that poplar and quaking aspen are one and the same. Again, the cottonwood is often called whitewood, which would lead some to think it the same as poplar. Now, my experience is that these are all different trees except the tulip-tree, which I believe to be the same as poplar, and so called on account of the blossom resembling a tulip. The name whitewood has simply been used because that is the color of the wood of all these different trees. The cottonwood, balm of Gilead, and quaking aspen, are all different trees, though very nearly allied to each other. The poplar is of another and distinct type. It yields honey in great profusion some seasons, while the other three yield nothing, to my knowledge, but propolis and pollen.

BRACE-COMBS.

Dr. Miller suggests that, in experimenting with thick top-bars, tin strips be tacked on each side of the top-bars to increase the thickness. Now, may it not be possible that the doctor's suggestion will bring forth fruit not dreamed of? Is it not a fact that bees are a great deal more inclined to stick wax to wood than they are to tin? Again, what harm (or good either) would it do if these same strips of tin were raised up $\frac{1}{4}$ in. above the frame (instead of even) and perforated same as the excluders? This is merely a suggestion. No charge for postage and packing. I give it free.

Santa Paula, Cal., Feb. 19.

R. TOUCHTON.

Friend T., I did not mean to say that the poplar and the quaking aspen were one and the same thing, but that in our locality the tree is called by both names, while in the South our whitewood, or tulip, is called poplar. I do not know how we can straighten up this confusion in the names of trees.

OUR QUESTION-BOX.

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 164.—*What width do you prefer for top-bars? For bottom-bars?*

1, 2. $\frac{3}{4}$ inch.

Wisconsin. S. W.

S. I. FREEBORN.

1, 2. $\frac{3}{4}$ of an inch.

Michigan. C.

A. J. COOK.

$\frac{3}{4}$ all around.

Illinois.

MRS. L. HARRISON.

1, 2. $\frac{3}{4}$ inch.

Illinois. N. W.

DADANT & SON.

I have always used them $\frac{3}{4}$ of an inch wide.

Ohio. N. W.

A. B. MASON.

Not wider than worker-brood comb. 2. If any different, narrower.

New York. C.

P. H. ELWOOD.

We make all of our frames out of $\frac{3}{4} \times \frac{3}{4}$ pine lumber—tops, sides, and bottoms all the same.

Wisconsin. S. W.

E. FRANCE.

One inch. 2. $\frac{3}{4}$ inch. After experimenting for years I adopted the above, and have no desire to change, at present at least.

New York. C.

G. M. DOOLITTLE.

Not wider than $\frac{3}{4}$ in any case, nor narrower than $\frac{3}{4}$; bottom-bars the same, so far as width is concerned.

Michigan. S. W.

JAMES HEDDON.

One inch, I suppose, because I have always used that width. 2. $\frac{3}{4}$; I have tried $\frac{1}{2}$, but that is too narrow, as the bees build comb around and under them.

Vermont. N. W.

A. E. MANUM.

Our top-bars are of inch stuff, running down to a beveled edge. Our bottom-bars of frames are $\frac{3}{4}$ inch wide, just the size of worker-combs—the best size for the prevention of brace-combs.

Ohio. S. W.

C. F. MUTH.

One inch, both for ease in manipulating frames and uncapping honey, although in this county the uniform width is $\frac{3}{4}$, being more convenient for the planing-mill men in cutting them from scraps in making hives. 2. $\frac{3}{4}$ inch.

California. S. W.

R. WILKIN.

I keep my preference for $\frac{3}{4}$ -inch bars until some other style of bar is proven a sure remedy for brace-combs. Then, if the desirable thing is not too awkward, I may adopt it. 2. Bottom-bars might be as narrow as $\frac{3}{4}$ if there were any object in having them different from the tops.

Ohio. N. W.

E. E. HASTY.

I have always used $\frac{3}{4}$ for both top and bottom. I find a wider top or bottom interferes with uncapping when the extractor is used. The wide top and bottom bar becomes a still further nuisance in this respect when closed-end bars are used. A spoon-shaped uncapping-knife would have to be used.

New York. E.

RAMBLER.

Such a width that, when properly spaced, there will be between the top-bars just a bee-space and no more. 2. A little less than the top-bars, in order to give the bees free passageway between them. I see nothing practical in being very nice about the width of bottom-bars unless we have some means of spacing them uniformly.

Ohio. N. W.

H. R. BOARDMAN.

1, 2. I do not know. I have always used them $\frac{3}{4}$ wide. I do not want them much less, and I am not sure that I want them wider. I am going to try 500 frames this season with top and bottom bars an inch wide. This is for brood-frames at fixed distances. For the ordinary hanging-frame I am very sure I should not want them wider than $\frac{3}{4}$. My frames for extracting are wider, but combs are thicker—7 in 11 $\frac{3}{4}$ inches.

Illinois. N. C.

J. A. GREEN.

1. That width which will allow $\frac{1}{8}$ of an inch between them. If 1 $\frac{1}{8}$ is the proper distance from center to center, then I believe top-bars should be 1 $\frac{1}{8}$ wide. 2. I should want bottom-bars just as wide as top-bars, if they would stay at regular distances apart. But with the ordinary hanging frame, if you look under the bottom-bars you will see they have a way of getting together and spreading apart, so that, to keep them from being glued together, they must not be more than $\frac{3}{4}$ wide. Even at that width mine are too often glued together.

Illinois. N.

C. C. MILLER.

I am a little surprised to find the testimony so universal for $\frac{3}{4}$; but, dear friends, is it not a good deal because we have used the $\frac{3}{4}$ so long, and have not tried any thing else? Dr. Miller makes a suggestion which I wish to emphasize. If your hives have movable bottoms, just take a look some time and see how the bottom-bars are spaced—I mean after you have put the top-bars in very good shape. By tipping the hive back from the bottom-board you can get a glimpse of the bottom-bars. Now, whenever I have looked at them it has seemed to me a little unfortunate that we should leave things in such shape, and expect the bees to manage all right with all sorts of distances, and combs even sticking together at their lower edges.

NOTES AND QUERIES.

We solicit for this department short items and questions of a practical nature; but all QUESTIONS, if accompanied by other matter, must be put upon a SEPARATE slip of paper with name and address.

ROYAL GLUE FOR LABELS ON TIN.

If you will use "Royal glue" for sticking labels on cans and pails, I think they will stay. I don't have any trouble in making them stick with it.

Washington, Ind., May 3.

MRS. S. D. COX.

EVERY THING SEEMS TO YIELD HONEY.

The past ten days have been good bee-weather, and bees are just booming here. All the little apiaries are increasing 100 and 200 per cent. My own is not swarming so much, but working in sections, and it looks as though I should have cases filled and capped by July 4—unusual here. Every thing seems to yield honey.

A. A. LEWIS.

Waterbury, Vt., June 24.

A GOOD FLOW.

I must have a great many more sections if the flow of honey continues as for the last three weeks. Swarming weather, hot and wet. J. BAGLEY.
Serena, Ill., June 28.

COLONIES IN THE OPEN AIR.

A few years ago a neighbor of mine, an old bee-hunter, found one on a poplar, on the outside, under a short bend, that I think had about 50 or 60 lbs. of honey. C. R. RUTH.
Elmispport, Pa.

CHAFF HIVES.

Is there any thing ahead of the chaff hive, described in A B C of 1879? GEO. F. KNAPP.
Springport, Mich., June 11, 1890.

[That is a question we can not answer. Our chaff hive has given splendid results in wintering. It is not as portable as the smaller hives, nor as handy to use. A. I. Root uses the chaff hive, and prefers it to any thing else for a general-purpose hive; although at the same time he would always have Dovetailed hives, or Simplicity, to use in connection with the chaff hives.]

A FATAL STING.

One of my neighbors, Samuel McAdams, was stung on the neck by a bee last week and died in 20 minutes. FRANK BUTLER.
Carrollton, Ill., June 30, 1890.

[This is a sad record, friend B.; but please let us remember that, if somebody should call for instances where people have been killed by horses or cattle, there would be a hundred or more such cases where we find one who has been killed by bee-stings.]

THE SEASON IN ILLINOIS.

The season here is very poor so far for white honey. The fields are white with clover, and the basswood is in bloom, yet the bees are idly lying out with the foundation in cases scarcely touched in many cases. I do not now think we shall have one-fourth of a crop of white honey. Similar reports come from all directions. C. H. DIBBERN.
Milan, Ill., July 1, 1890.

IMPROVING POOR HONEY.

I have honey that I have kept in an open-mouthed vessel for two years, and it is still foamy. What can I do with it? GEO. GOULD.
Villa Ridge, Ill., July 7.

[You do not tell us whether the honey is good quality. Probably not. Sometimes, in such cases, running off the liquid portion and then melting the candied part will give you very nice honey—that is, from the candied part.]

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

SECTIONS NOT SOLD BY WEIGHT, BUT BY THE PIECE.

If you will permit, I should like to correct the impression you seem to have, that honey is invariably sold by weight. According to your reply to friend E. C. Newell, one would suppose you certainly had overlooked the truth in this matter. Mr. Newell is correct in his statement, page 464, that grocery men invariably refuse to buy or sell any other way than by the piece, especially after their first years' selling of section honey. Neither, as Mr. Newell says, will they allow you any thing for extra weight. This thing I have thoroughly tested in our local market. My grocery man suggested to

me to have my sections made at least $\frac{1}{4}$ inch narrower, as I was losing from 2 to 3 ounces on each section this part of the season, and he couldn't help it. Mr. Newell says he strongly objects to your statements in this matter, and your reply will still surprise—yes, grieve him, to think you are so out of it, and at the same time ignore, apparently, all that he has invariably found to be the case. Please let Mr. Newell have the satisfaction of knowing there is at least *one* who indorses his statement; and, if I am not greatly mistaken, others by the score are ready to do the same.

I want my sections hereafter $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{8}$, in place of $1\frac{1}{8}$, then there will be no possibility of so much overfilling. I should like to hear the views of others on this matter. I am aware that, in the fall, when our crates begin to have light weight, grocers would rather take in by weighing. But my understanding is, no reduction the season through.

Pine Grove, O., June 24, 1890. S. DANIELS.

That is right, friend D.; give us the facts, no matter whom it hits. If sections of honey are sold in many places for so much apiece, we certainly ought to know it.

A HONEY-WELL; A MAN BORES INTO A BLUFF, AND SECURES THE SWEET ARTICLE BY THE BARREL.

The heading as above, together with the following, appears in the *Cleveland Leader* for June 27:

LOUISVILLE, KY., June 27.—A successful boring for honey has been made in North Tennessee. For many years swarms of bees have been noticed by boatmen at Fox Bluff, on the Cumberland River near Franklin, Ky. The bluff is 170 feet high, and the river's channel runs directly under it. The bees have been observed about a big fissure near the center of the bluff, and the opening could not be reached from above or below without great danger of being stung to death. As the bees had never been robbed it was believed a large amount of honey was stored in the cliff. Secretly a well-borer named Staks visited the bluff, and was at once impressed with the idea that he could reach the wonderful honey-storehouse with his drill. After some coaxing he persuaded a number of farmers to undergo the expense, and a three-inch hole was bored from the top of the bluff. At a depth of 85 feet the drill struck the honey. Barrels and tubs by the score were filled and carried off to neighboring farms, and the syndicate has sent to Louisville for more receptacles.

It seems a shame to give space to any such silly statement as the above, and we would not do it were it not that, whenever some newspaper reporter manufactures such a yarn, it comes to us right and left. Oil and gas may come out of a hole drilled in a rock, but not honey.

PUTTING YEAST INTO HONEY TO KILL OFF NEIGHBORS' BEES.

Last spring I had 10 colonies (hybrids), and they increased to 40 by fall, besides giving me considerable honey. I wintered them indoors; placed them in tiers against the end of a building, and packed them in straw. Most of them lived till spring, but have dwindled away since, except five colonies, and they are not in the best condition. I wintered them the same way the two previous winters, without any loss. A neighbor had some trouble with robbers. He closed his hives and left a hive of honey, without bees, open, pouring yeast into the honey (so it is claimed). My bees, of course, went there. Is it possible that that has been the cause of the disaster? Will it be safe to give the same

hives to new swarms, there being considerable honey left in most of them?

WHAT DO THE COURTS DECIDE ON THE MATTER OF DESTROYING BEES WITH POISONED HONEY?

Has it been tested in courts whether people have a right to destroy bees, and endanger consumers of honey that way? If it would not be too much trouble, I wish you would reply to this in GLEANINGS.

A. HENNINGS.

Alabama, Wis., June 3.

Friend H., this story about feeding bees yeast in their honey is very old. I do not believe it was that that killed your bees; but I am inclined to think, from what you say, that they had the spring dwindling. I do not know that the matter has ever been tested in regard to poisoning bees; but it certainly would be a very clear case, for our laws are very severe on any one who wilfully poisons domestic animals of any sort.

WIDER ENTRANCE FOR THE CHAFF HIVE.

I see by GLEANINGS you have abandoned the 8-inch entrance to chaff hives, and adopted the full width. If you will jog your memory I think you will find I was one of the first if not the first to insist upon full-width entrances to chaff hives, both one-story and two-story. If you please I should like to insist upon another improvement. There will not be any more demand for brood-frames with top-bars $\frac{3}{4}$ wide. Many of us think $1\frac{1}{2}$ too wide. Many of us wish to continue the use of metal corners. It is hard to use all-wood frames and be a Christian at the same time. I want to use metal-cornered wired brood-frames with top-bars one inch wide and $\frac{3}{4}$ thick, wired as you have been wiring them, with tin bar in the middle.

Bonney, Pa., June 20, 1890 PHIL0 S. DILWORTH.

Yes, you did suggest making a wider entrance; and from what you and one or two others said, together with our own convictions in the matter, we commenced this spring to make them full width of the brood-chamber. There is no reason, if single-walled hives have the full-width entrance, why the chaff hive should not. Don't be too positive that there will be no more demand for a narrow top-bar $\frac{3}{4}$ inch wide. The *tendency* of the times *looks* that way.

THICK TOP-BARS; RUSHING AFTER NEW THINGS A DAMAGE.

I have just read in GLEANINGS, page 182, "It is a serious matter to lumber our homes and our apiaries with things that may, after a little while, be discarded as useless for the purpose for which they were recommended." Now, I will venture a prophecy. The wide and *thick* top-bars that you are just now booming so vehemently will turn out just as stated above. They will soon be regarded as an intolerable nuisance, then away they go, and what a time there will be to get the combs out and fit them into other frames! Top-bars one inch wide and $\frac{3}{4}$ thick, properly spaced, will prevent brace-combs as effectually as one inch or $\frac{3}{4}$ thick. I know whereof I speak. I saw it tried; but there are objections to wide top-bars, that make me extremely reluctant to go back to them. I have not used a honey-board since I discarded the old Langstroth style of hive, and I am satisfied in my mind that I never shall. My hive is so constructed that a super of the same length and width is just right for 32 one-pound sec-

tions $1\frac{1}{2}$ wide without separators, and leaving room to slip in a $\frac{3}{4}$ board in one side as a clamp. I then place two strips 7 in. wide, of painted cloth, between the sections and the brood-frames, and that does the business to my satisfaction. The making of frames an inch or $1\frac{1}{2}$ involves quite an extra expense over frames just $\frac{3}{4}$ wide. In most places suitable lumber can not be had without special order for the purpose, and that at once involves an extra price, to say nothing of the extra quantity.

G. B. REFLOGLE.

Centerville, Iowa, Mar. 12, 1890.

What you say regarding thick top-bars *may* be true; but if we reject every thing new *because* new, apiculture would be at a standstill. On such a basis the world would never have had a sewing-machine or a steam-engine, and you possibly might have been plodding along without movable frames. No, friend R., it is worth our while to properly examine into the merits or demerits of the new, and then use a little discrimination. Have we not urged, in almost every number of the journal, to go slow and try a few, and, if the few justified trying more, try more? If you will turn to our catalogue you will see that we sell thick-top-bar frames for the *same* price as the thin ones. There is more lumber in the former, but they are more cheaply made. Thin top-bars are quite liable to sag, but the thick ones will hardly be affected by the weight of combs. Top-bars $1\frac{1}{2}$ inch, properly spaced, will not prevent burr-combs with us.

E. R.

THE DOVETAILED HIVE AND KEENEY'S WIRING.

The Dovetailed hive is very neat, and I shall like it better after using a while. I am not sure about the slatted honey-board. I put in the nine slats and placed them even. Before the super is put on I find the bees will bridge their frames to the cover. That may be because the frames have already been plentifully bridged on top when used in other hives where I use a cloth. But I scraped the top-bars as well as I could before putting in the frames. I find it necessary to put on the enamel cloth. The new plan of wiring frames, introduced by E. D. Keeney, I have tried with improvements suggested by Ernest; foundation only four inches deep, and stick one edge into the slot that was made for comb-guide. It works wonderfully well.

Hopkinsville, Ky., June 9.

" D. F. SAVAGE.

NOT AGAINST PERFORATED ZINC.

Spring opened with bees in good condition. I did not lose a single colony until April. A neighbor asked me to assist him in overhauling his 30 colonies, when we found 9 dead. I told him of my success in wintering, not having lost a colony in 7 years, the entire period I had owned bees. But after a week's rain I told him a different tale. I had lost 8 colonies out of 18. But after the weather settled, the little fellows went to work in earnest; and up to June 14th I had taken 522 lbs. of as fine clover honey as one could wish. I will add, also, that my hives with perforated honey-boards did much better than those with wooden ones. At this date the honey-flow is about over, as we have little else here besides clover that yields honey sufficiently to store in supers.

E. W. STAYTON.

Bowling Green, Ky., June 21.

The statement has been made, that per-

forated zinc diminishes the amount of honey stored in the supers. The testimony above doesn't point that way. Bees will store honey just as well above perforated zinc as they will without any.

ANSWERS TO QUESTIONS; WAGES FOR EXTRACTING, ETC.

1. One of my old hives has plenty of bees, but had little brood, compared with others during the honey flow, and they stored no surplus at all. Is the queen too old? or what is the cause?

2. If a man goes out extracting for other beekeepers, what is the usual compensation? Do you think 5 lbs. per hive too much? or would it be more just to take a certain percentage?

3. I want to establish an out-apiary next year, with a party who keeps about 6 to 10 hives himself. He wants 5 lbs. of honey for every hive of mine, and is willing to give me 5 lbs. for every hive of his for the care of his, both parties keeping their own increase, if any. Is this arrangement just? If you think the answer to these questions will interest others, you may publish the same.

Olmsted, June 26.

M. R. KUEHNE.

1. Queens during or just before swarming time very often stop or diminish laying temporarily. After the swarming season, or after the colony has swarmed to a new location, the queen will commence in good earnest.

2. About \$2.00 or \$2.50 per day ought to be fair wages for extracting, the person proposing to do the extracting furnishing the extractor. Five pounds per hive would be pretty big wages.

3. The arrangement proposed would hardly be fair. Suppose you owned, at the out-apiary, 100 colonies, and the other party owned 10. You would have to give him 500 lbs., and he would give you in return but 50.

PROSPECTS POOR FOR THE LOCALITY OF E. FRANCE.

Mr. Root:—When you were having your rainy weather in Ohio we had a three-weeks' drouth. Now we are having rain and floods—rain, rain, rain. Cornfields are green with weeds. White clover is scarce—that is, old enough to blossom. I was at one of our bee-yards the 19th, and could put all the clover blossoms that I saw for five miles, into a peck measure. But the young clover is thick all over the ground; but that won't blossom this year. Bees have had a hard time to make a living for the past three weeks. We went through one yard yesterday. I don't think they had, on an average, one pound of honey per colony, and many did not have enough for supper—not a bit of new comb built yet. Basswood looks promising.

E. FRANCE.

Platteville, Wis., June 21, 1890.

WHY THE BEES DWINDLE.

I should like to ask you for a little advice. I bought me a swarm of bees one year ago this spring. Last season was a bad one for honey. The bees filled the hive full of comb, but did not make enough honey to last them through, so I fed them all winter when the weather was warm enough. This spring the bees were in good condition, and plenty of them; but for some cause they have dropped off, and I don't think there are fifty bees in the hive. I have watched them closely, and I don't think there have been any moths near them, but I think they grow less from day to day. Will

you please advise me in regard to the matter? I should like to raise bees if I can make a success.

New Haven, Ct., June 26.

E. W. EASTER.

From your letter we gather that the colony you mention was queenless, and of course they would then dwindle down to mere nothing just as you state. The colony is now probably too far gone to help matters any by giving them a queen. You could very easily make another start by buying a two-frame nucleus and an untested queen. These if the hive is Langstroth size could be put right into the hive where the bees died, and in a very short time you would again have a good colony of Italians for the next winter. If your hive does not use the regular L. frame you had better purchase a pound of bees and a queen.

WHY DID THE QUEENS STOP LAYING DURING THE HONEY-SEASON?

I should like to ask you a question in relation to my bees, and, in fact, all the bees in this place. They are dying a natural death, for the queens have not laid an egg for six weeks; and what the cause is I don't know. It is not for the want of stores or honey-flow, for there have been hundreds of acres of alfalfa in bloom of late, and the weather is not unfavorable.

ANOTHER POISONOUS HONEY-PLANT.

The bees worked well for a couple of months since, on a weed that is called loco. Now, that same weed is very poisonous to horses when they eat it, and also to cows. It is not always fatal, but they get crazy. Is there anything in the flower that will prevent queens from laying? While the bees worked on it the queens were laying, and colonies increasing; but when the loco stopped blooming the queens stopped laying, and consequently the bees are dwindling down to nothing. Have you ever heard of a similar case? There has been loco here every year since we started bees here four years ago.

JAMES CHRISTIANSON.

St. Johns, Ariz., July 1.

Friend C., it seems to me you have answered your own question; namely, the weather was not favorable. Queens will not lay, as a rule, unless honey is coming into the hive; and no matter if there are hundreds and thousands of acres of blossoms, there are times when there may not be a drop of honey for the bees to get.—Perhaps Prof. Cook can tell us something about the poisonous honey-plant you mention. I do not remember to have heard of it before. Even though all you say be true, I hardly think the honey is poisonous or has anything to do with the non-laying of the queens.

A QUEEN OUT FOR A PLAYSPELL.

I received the queen in fine condition, and she is now doing finely. She commenced laying the second day after being received, and has filled three frames of eggs. I introduced her as per directions, and as I took a frame from the hive I stepped over to arrange frames, and see all was right; and on coming back in about fifteen minutes (I don't think the time to be any more) my new queen was poising at the entrance of the hive, taking her bearings very carefully. I dropped to the well-known position of a bee-hunter, to keep her against the horizon, and had the pleasure of seeing her majesty

have a fine frolic. Her circles included about two acres; and as she cut the air it was fine music to hear. In about ten minutes she returned, as nice as a veteran worker. After I found her laying I clipped her wing. All is well that ends well. I took a look at the cage and found three cells completely torn down. I think she liberated herself very quick. I lost my first queen about twelve days before I ordered this one. The most probable cause, I think, was, she took a flight and was caught by a bee-bird, as I have shot 25, and examination proved they really catch my bees.

Vine Creek, Kan., July 2. WM. H. DODGE.

Friend D., you have struck upon something that was fully discussed some years ago, and called forth considerable comment and some anxiety. You say a fertile queen took wing, to the extent of flying over perhaps a couple of acres. In your case she did not meet a drone. May be a queen that has once laid worker eggs never meets a drone afterward; and I believe that is the general rule in teaching. But for all that, I am sure I did see one queen, that we imported from Italy, take wing just as yours did. I do not know what she took wing for, nor just how long she was gone, for I only saw her returning. We have other testimony that seems to indicate quite strongly that queens, after meeting the drones once, fly out one or more times after this meeting.

ARE BEES ASSESSED AS PROPERTY?

I should like to know whether bees are assessed in your State or not, or in any other State that you know of. The county officers wanted the assessor to assess them. I told him they were not assessable unless there was a State law to assess them. He thought I was right. He wanted me to write and see if they were assessed in other States.

JAS. R. WHIPPS.

Le Sueur Center, Minn., June 18, 1890.

I do not know what the prevailing custom is; but I think bees should be assessed with other property. In fact, if the assessor should pass by my bees I should feel slighted. If hives of bees are not property, then we had better all of us quit the bee-business. This matter has been up before, and there was some discussion on it some years ago. I do not want any thing from my neighbors unless it justly belongs to me; neither do I want any thing nor any privilege from the government of the United States unless it is fairly mine. Of course, I agree that there are things of so little use, or of a value so uncertain, that it is not worth while to tax them. If your bees and fixtures would not sell at public sale, then I should say they were not worth taxing. As hives of bees do, however, sell for something with other stock, this customary selling price, it would seem to me, should be the proper value for taxation.

WHY BEES SWARM OUT, ETC.

Can you give me any reason why a new swarm will settle in a new hive, and remain a few days, and then start out and leave the hive? Also, why a new swarm will enter an old hive where there is a good working colony already in it, and remain in it, and apparently work with perfect harmony? I had such a case the other day. Is it not advisable for a

very strong colony to have as many as four or five supers placed upon the hive at once for ample room to work in?

C. W. YOUNGMAN.

St. Paul, Minn., June 21, 1890.

The matter you mention is fully discussed under the head of "Absconding," in the A B C book. Absconding swarms often try to force an entrance into any sort of hive—one containing bees or one without. Sometimes the colony occupying the hive will receive them peaceably, and sometimes they will not. I would place enough supers on a strong colony to give them all the room to work, but not too many at once.

QUEENS FAILING TO HATCH BECAUSE WRONG END UP.

I have been a bee-keeper for seven years, during which time I have had three queen-cells that, having failed to hatch, an examination showed the queens were wrong end up—that is, their heads were turned toward the base of their cells. Is such a thing common? I have read my A B C book, but I don't find that you say any thing about such mishaps. The latest one I find I send you by to-day's mail, which has not been removed from the cell; but those that I have examined before, appeared perfectly developed, and I suppose that, if the cell could have been torn open just at the right time, they would have been all right. The one I send you should have hatched a week since. Do worker bees ever turn up that way?

L. HALL.

Sparta, Miss., July 4.

This matter of queens and worker bees being found in cells wrong end to, has been commented on several times through our journals. Sometimes they gnaw out near the base of the cell, and at other times they are found dead in the cells. I do not know where the trouble is, unless friend Doolittle's suggestion hits the point—somebody shook the frame to get the bees off, and the queen wiggled around. If the frame, however, was never removed from the hive, and shaken, I suppose we shall have to admit that nature sometimes makes a blunder.

BURR-COMBS; PREVENTING WITH CROSSWISE SECTIONS.

a. Would sections tend to prevent burr-combs if put on crosswise of the frames? b. Would as much surplus be stored in them crosswise as lengthwise?

Falfa, S. C., June 3.

G. D. MIMS.

I believe as much honey will be stored where the combs in sections are at right angles with those in the brood-frames as by the usual way. I do not believe the burr-comb will be any better, but, on the contrary, rather worse.

QUEEN SENT.

The queen ordered of you June 28th arrived in good condition July 3, and was introduced according to directions July 4th. I looked in the hive to-day, and found her released and all right. Thanks for your promptness in filling orders. She was darker than I expected to see, but, of course, she is all right. This is the first one I ever saw; but I supposed they were very bright, like the workers.

The honey-flow is about over here, and has been very poor indeed. I notice reports in GLEANINGS from apiarists, that vary from 50 to 200 lbs. per colony. Now, I should just like to have you tell

me how to do this. I am very much interested in bees. I like to work with them, and am very fond of the honey. We think that 50 lbs. per colony is a big yield. We have no artificial pasturage, except a little buckwheat. There are a few colonies upon almost every farm, but nearly all are blacks, and in box gums. The owners seem to think these boxes as good as any movable-comb hive. That corn you sent me in the spring is fine for early use. I shall save seed from it. C. C. POLK.
Bradford, Ala., July 5.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

THE HONEY YIELD.

FOR the last few days we have had an unusually heavy yield of nectar. The busy toilers have been coming in and dropping on the entrance by the score. At night the whole apiary has been one continual roar, and the fragrance of newly gathered honey is as apparent to the nose as the roar is to the ears. If this state of affairs should be general, and continue, there will be a good yield throughout the United States.

Later.—The weather has turned cool and honey has stopped short off, and robbers, especially from the hybrid colonies, are beginning to nose about. When we had hot days and hot nights the flow of nectar seemed to be very heavy; but now, the 11th, none seems to be coming in.

THE ALLEY DRONE-TRAP.

This year we were obliged to buy a good many colonies, and there were not a few hybrids among this number. As we were rearing queens right along, it would not do to let the half-blood drones have liberty in the air. All undesirable drone brood was uncapped after the hybrid queens had been removed, and then the Alley drone-traps were attached to the entrances. Two or three times the upstairs apartment of the trap was full of drones, that had gone up through the cone, and, being imprisoned, died.

IS THE TRAP A HINDRANCE?

The question has naturally come up as to whether a trap is a hindrance to the workers. For a few days it does disconcert them a little; but after they have become accustomed to it, they pass readily through the zinc. Bees have to learn a little knack in getting through the zinc, and, after having acquired it, they slip through in a twinkling.

There is just one improvement that I would suggest to friend Alley. He has already obviated the difficulty somewhat in his automatic swarming arrangement. The trap is too small. As the perforations can not be any larger, there should be more of them. With the ordinary size of trap, during night, when bees are evaporating honey, a good many of the bees will get around the openings, and very materially retard rapid evaporation. If the night is at all warm, the bees cluster out and cover the trap almost entirely—making the matter

somewhat worse. During the honey-season, bees ought to have the full-width entrance of the hive.

FOUNDATION, AND WHAT DRAWS OUT BEST.

I have been making quite a number of experiments on different kinds of foundation. For the brood-nest, I find that the heavy brood (so styled in our price list), running 5 feet to the pound, gives altogether the best results. The cell-walls in this are heavier, and are circular, leaving a little more wax in the corners of the hexagons. The light brood (7 ft. to the lb.) which we ordinarily use for the wired frames, has a tendency to be wavy on being built out, and on horizontal wiring it would not do at all. Now, may this not account for the difference in the reported results of horizontal wiring as to whether foundation will bow out or not? If heavy brood foundation is used with the horizontal wires, no trouble will be experienced. Even on a perpendicular plan, light brood foundation, when drawn out, has a wavy appearance, because the bees will stretch the cells a little in drawing it out.

KEENEY'S METHOD OF WIRING.

This works very satisfactorily. Even with light brood it does as well as with the perpendicular plan; but with the heavy brood it is just perfect.

THICK TOP-BARS.

They are working very successfully. Burr-combs have been built up above thin top-bars, but the thick ones are free so far. They do not seem to sag very much yet, either.

THE HOFFMAN FRAME.

The modified Hoffman frame, as described recently in GLEANINGS, has been put into the apiary for testing. It certainly has some very desirable features about it, and the bees do not gum them together nearly as bad as one would imagine, and they are in a hybrid colony at that. By the way, is it not a fact that

HYBRIDS ARE WORSE ON ACCOUNT OF PROPOLIS?

We have quite a number of half-bloods that have filled their tin rabbets level full with propolis. With this kind of bees, metal rabbets are no better, nor as good, as the plain wood bearing. I do not know, however, that I have noticed Italians propolize things up in this way. Perhaps this is one of the reasons why the majority of bee-keepers prefer plain wood bearings in preference to tin rests.

HYBRIDS.

Oh dear! I wish there weren't a hybrid in the apiary. It has been several years since we had so many colonies in the yard at once; and during the intervening time we have had almost exclusively Italians. Then we could work a greater part of the time without a veil; but now a veil is an absolute necessity. On hot days, when it is hard enough at best to keep cool, a veil around the head is any thing but pleasant. Perhaps I should remark, that all the hybrid colonies above mentioned had their old

queens removed long ago; but somehow those old black fellows still live, and won't die off, although their old queens were removed something like two months ago. I have felt several times as though I wanted to paddle the whole boodle of them to death, as described in our last issue, in this department, under the head of "cross bees."

CARNIOLANS.

These bees are still doing well. The hive is full, and running over with workers, and we have been giving them empty combs to give them room. Strange enough, these fellows have not attempted to swarm yet. The Carniolans we had last year would have swarmed themselves out of existence with half of these conditions of prosperity.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

That art on which a thousand millions of men are dependent for their sustenance, and two hundred millions of men expend their daily toil, must be the most important of all—the parent and precursor of all other arts. In every country, then, and at every period, the investigation of the principles on which the rational practice of this art is founded ought to have commanded the principal attention of the greatest minds.

JAMES F. W. JOHNSTON.

GARDENING IN JULY.

ISN'T it fun? I have just come in from the fields, and I have so thoroughly enjoyed the morning that I want to tell you something about it. Just about this time of year, there is very often a scarcity of potatoes. Old ones are all gone, and the stock of new ones is inadequate. Yesterday Mr. Stevens said there was not a potato in town; and after people had been at all the groceries and found none, they came down to me. Men, women, and hotel-keepers came with long faces, to know whether I could possibly give them some potatoes for dinner. Now, you may think it is funny that I should rejoice to see everybody in trouble. Well, you know Uncle Amos did not mean just that. I will tell you why I rejoiced. Away back in the spring we started a lot of Early Puritans and a lot of Early Ohios in the greenhouse. When they were so big that they could not stay in the greenhouse any longer (they were getting so "long legged") they all laughed at me for turning my potatoes out of their warm quarters into the snow and storm and frost. There was not a bit of ground dry enough to work, except some ridges where celery had been dug, that I have told you about. We split the ridges with a plow, and made a pretense of getting mellow dirt for my greenhouse potato-plants. We set them out as best we could, with many misgivings. Some fine weather came on, however, and they turned to a rich thrifty green, and began to do nicely. Then came frosty nights, and we fussed to lay them down and cover them with fine dirt that could not well be found, the ground was so wet; but with a strong plant growing out of a whole potato, even if it does get nipped with frost it soon starts out again. Well, on this 7th day of July there were great masses of foli-

age, and the hard ground that had never been plowed to amount to any thing was bursting open with the potatoes underneath. We dug them, such as they were, and people went away happy, even if the potatoes did cost *50 cts. a peck*. I had a little misgiving, for I feared they might not be nice for cooking. But my wife gave us a sample of these for breakfast, that allayed all my misgivings. Early Puritans are just beautiful when cooked as Mrs. Root knows how to cook them, even if they are *not* fully grown. It takes about five hills to make a peck at the present stage of growth. But ten cents a hill (each hill representing a single potato when planted) pays us very well. Of course, we select the most mature-looking hills to dig first. The only thing I felt sorry about is that I did not start *more* potatoes in the greenhouse, and plant them in celery-ridges in just that way. At the same time we planted the potatoes in the greenhouse, we found a strip of ground that would work very nicely by turning under some rye that was about knee-high. We put peas, kidney wax beans, and corn, in this strip. I knew the peas would be all right; but it was so very early for corn and wax beans, I thought I would try only four rows of each. Well, the corn and beans had so many ups and downs, and made such a very poor growth for many weeks, that I thought I had wasted my time and pains; but just now they are yielding beautifully—I mean the beans and peas. The corn will be ready in about a week more. We get *50 cts. a peck* for peas, and *10 cts. a pound* for wax beans; and Mr. Stevens says that he only wishes he had four times as many. We have been getting this price for the peas for at least four weeks, and I should think for over two weeks on the wax beans. Two quite small boys pick all the peas, and two more pick the wax beans. I have now got these boys taught so they pick only peas that are just right—none of them "too thin," neither do they let any get too hard. I have also taught them so as, with my assistance, to keep just enough ahead for the demand, and no more, so our customers get them just freshly picked. The wagon leaves here at six in the morning, and then comes around for a fresh supply again at nine. So our small boys pick late in the evening, just what is wanted to start out with in the morning. Then early in the morning, before it gets real hot, they get just enough for the wagon when it gets around at nine. About this time they are tired enough to stop and rest, and by three or four in the afternoon they are all ready for work again. Our berries are picked in much the same way. There is nothing like being able to tell your customers that the peas, beans, berries, etc., have just been picked within an hour, or two hours at the furthest. We have a good careful man to look after the boys, to see that they do not get to playing, nor eating their berries, and then I get around among them three or four times a day. I tell you, I just enjoy gathering up the stuff. Besides the trade on the wagon, we sell quite a little stuff at a sort of berry-stand between our lunch-room and

counter-store. This is where we display and sell our honey also. Well, it is my privilege to gather up tempting things from the fields, and make a little display of them on this berry-stand. As we have unexpected calls for all sorts of stuff at all hours of the day, we find it exceedingly convenient to scatter baskets all over our grounds.

When we have new comers, I find it a hard matter to keep them from carrying the baskets up to the toolhouse, especially nights. These market-baskets (peck, half-peck, and half-bushel) cost only 30 or 40 cts. a dozen; and it does not pay to carry them in nights, not even when it rains. Very often we have a sudden order for something to meet the trains, especially at this time of year when picnics and excursions are in vogue. If baskets are in the field, I can call from the office window to Mr. Weed, whose place is in the plant garden, and he can go to the top of the hill and call to the boys to bring up what is needed, providing baskets are where they can grab them up quickly, and set them at work. Now, when I take my morning walks, I take a basket of suitable size and gather up what peas are picked. Then I fill another with string beans from where they are picking; a third one with new potatoes; a fourth with black and red raspberries; may be a fifth with currants and gooseberries. By this time I am ready to look for a wheelbarrow. By the way, we have wheelbarrows scattered over the premises almost as plentifully as baskets. I think there are seven altogether. When I get more samples than I can carry I call to some one to meet me with a wheelbarrow.

Now, when the boys bring the stuff in from the fields, they just dump it down in all sorts of disorder. I can not teach anybody (at least I have not succeeded so far) to fix up a display of fruits and vegetables as I fix them up. First, I dispose of all partly filled baskets, by selecting a basket of proper size, so each one will be heaping full. "Heaping full" means good measure, and then you know what the Bible says about good measure. Then I put all the currants by themselves, all the raspberries, gooseberries, peas, wax beans, giving the berries the most prominence, peas and beans next, setting the potatoes on a box or stool a little lower. Before I get things fixed, a lively trade starts up, and my display is very soon disordered. When I can be spared, however, I just enjoy seeing things go off; and before any thing is out, some of the small boys that are almost always standing around (feeling sure by past experience that I have work for them) are ready to go to the fields and bring in a fresh supply. By the way, this year we are employing quite a number of little chaps at only *two cents an hour*. Mr. Weed and the time clerk concluded that they would be worth that much, even if they did play a good deal. Well, I really enjoy teaching these "two-cent" little fellows how to work and how to do business. There is a full understanding between us, that, when they prefer to be their own bosses—that is, to be free from any obligations—they can be off from duty by simply

marking their time off on the slate. There is a small slate on purpose for the men, separate from that used by the big men and women. Sometimes when I ask them to do something they reply, "Why, Mr. Root, I am not at work just now; but if it is some little thing you want done, I will do it, *without charge*."

Just think of the idea of these little fellows working on a salary of two cents an hour, being liberal toward myself, or toward their "boss," who employs toward 200 hands, at an expense of more than \$20.00 an hour! I mentally thank them for the example they set me; and may God help me in a like way to be liberal toward *them*, with *their* small modicum of strength and judgment. Just a few minutes ago I saw one of the younger ones with his berry-basket hitched to his suspenders in such a way that he can pick berries with both hands, instead of picking with one hand and holding the basket with the other. This reminds me that, while in Wisconsin, I saw a sort of tin box to be strapped around the waist, used by friend France's pickers, for picking blackberries. This tin box has no bottom, but it has a funnel-shaped cover. This cover drops the berries in such a way as to spread them over the top of the box, so as to have it nicely rounded. This year our berries are all picked by the hour. We like this better, because we can stop and start as the market demands, set the boys at any moment hoeing or weeding, without marking the time off or on. Besides, I think there is a better feeling among the children—less strife and jealousy—where they have regular wages by the hour. Of course, the rate of wages is gauged by the amount of work. Our strawberries have brought, during this season, from 10 to 15 cents, few if any being sold for less than 10. Raspberries have only once been down to 8 cents, and that was Saturday night. Of course, however, all of our stuff brings a better price because of being freshly gathered and delivered in tempting shape, right at the homes of the consumers. Now, in conclusion, let me say again, "Isn't it fun to be a gardener in the month of July?"

THE OREGON EVERBEARING STRAWBERRY.

Friend Root:—Will you please let us know something about the new everbearing strawberry? I got 12 last fall, and planted them in my greenhouse. They made a nice growth, and are now in my garden, full of handsome berries. They are constantly sending out more fruit-stems, but not a runner appears. I have one plant with not less than eleven fruit-stems, and the berries are fully as large as Jessies. If it is going to keep it up at that rate all summer, I should think that one plant ought to produce half a bushel of berries alone. But how can we multiply them, if they will not send out runners? Pulling the stools apart is the only way I know of; and then the question comes, "Will that not kill them?" and, when is it best to do it?

Port Clinton, Ohio, June 9.

J. JOHANNSEN.

Friend J., we also had about a dozen plants in the greenhouse. They commenced sending out runners just before fruiting, and we have perhaps 40 or 50 young plants.

Like yours, our old ones are still blossoming and sending out fruit-stems. While the fruit is not as large as the Jessie, it is of very fair quality. I, too, have been getting a little excited about this strawberry. But these plants are in very rich plant ground—in fact, nearly half manure, and some other varieties of strawberries under the same circumstances are also blossoming and bearing fruit; and I presume this is caused by the very rich ground they are in, and the continual watering they receive when the celery plants and others adjoining get their heavy waterings every three or four days. In fact, a little patch of Jessies in the greenhouse is still giving us a box of berries every other day, when those in the field ceased bearing more than two weeks ago. Is it not true, that special treatment may make any strawberry-plant everbearing? I am sure I can not tell why yours do not send out any runners. The introducer of the plant has an advertisement in this issue, but I do not know his prices. I do not believe that dividing the stools would answer very well.

ANOTHER STRAWBERRY REPORT—80 QUARTS FROM
A PIECE OF GROUND 5X82½.

Friend Root:—The strawberry-bed you saw in my yard in Boscobel, the day you arrived there, is 82½ feet long by 5 feet wide. We picked 80 quarts of as fine berries as any one ever saw, from said bed. They are the Jessie and Bubach varieties. The little boy measured one that was 5½ inches around. This bed was only eleven months old when it produced the 80 quarts of berries. You saw this bed a few days after it was set out, it being a very dry time.

BENJ. E. RICE.

Boscobel, Wis., July 2.

Dear friends, here is a hint for you. After your early crops on your garden, manure the ground well, turn it under, then pulverize and work it thoroughly. Be sure to make surface-drains as well as underdrains, so that heavy rains can not beat it down solid, and in only *eleven months* you can have such a yield of fruit as friend Rice speaks of. The sight of the pretty little bed of berries took my eye at once, and I made up my mind then, that, if he *kept* them looking as nice, he would get his reward.

THE IGNOTUM TOMATO IN AUSTRALIA.

From packet received, containing 32 seeds, I was successful in obtaining 20 fine healthy plants, every one of which has proved true to name—at least, not like any thing grown here before, save Mikado, from which, I am inclined to think, this is a sport. I say this, because the Mikado was first out here; but if the Ignotum has been, I should call the Mikado a very poor sport from the Ignotum. It is very strong, and hardy in habit. The fruit is very uniform in size and shape, quite smooth, no corrugations. One tomato that I measured and weighed gave the following results. It was the finest one in view at the time. Size, 17 inches around; weight, 22½ ounces. The 20 plants yielded up to date (they are still bearing) 342 lbs. of fruit. If planted like the 20, on similar land, and the conditions the same, the yield would be just 42 tons of fruit per acre.

R. PATTEN.

Binni Apiary, Cowra, Aus., May 31.

EGYPTIAN ONIONS; GROWING TOMATOES IN THE
GREENHOUSE, ETC.

Mr. Root:—Can those Egyptian onions be grown under the greenhouse benches where they will receive little or no sunlight? If so, what time shall we sow the sets to have them fit for market in March and April? Tomatoes bring about a dollar per bushel in this place when they first come into market; but after they become plentiful they are slow sale at 30 and 40 cents. Now, what I wish to know is this: Why can we not have them very early by sowing the seed in a greenhouse in the month of January, or even earlier, and growing them in 6 or 8 inch pots till the middle of May? Will it not pay?

Cokeville, Pa., June 28.

JOHN MAJOR.

Friend M., the Egyptian onions will do exactly what you wish; in fact, I have thought, during this past spring, they do nicer in the shade than anywhere else; that is, they are more white, crisp, and tender. The way we manage is as follows: The little sets, or onions, on top of the stalks, are put in during the present month of July. We just pick them off and strew them pretty thickly in drills as we would peas, in good rich soil. If land is plentiful, put them far enough apart to cultivate with a horse. If you wish to have more on a small quantity of ground, put them only one foot apart. They will come right up and grow, and make a very pretty show in a garden right during the fall months. Any time in February or March, when the ground is not frozen, dig them, and set them in rich soil under your greenhouse benches. The sudden warmth will make them think spring has come, and they will grow to your heart's content. Those left in the field will be a month or two later. During the past spring we have sold wagonloads of them at 5 cts. for a bunch weighing 8 oz. Those forced in the greenhouse brought 5 cts. for a bunch weighing a third of a pound. The foreman of our sawroom has a little greenhouse of his own construction. He wanted it to play with, just as I use ours to play with. The first week in July he informed me he was selling tomatoes. The tomatoes came from plants kept in his greenhouse, in pots, until they had blossoms and little tomatoes on. When the weather admitted they were transplanted into open ground, and I presume he gets as much as \$2.00 a bushel for all he has now to spare. To be sure, it will pay any one who will take the necessary pains and care.

A GOOD REPORT FROM THE BUSH LIMAS.

The bush lima beans you sold me seed of are looking finely—just covered with blossoms, and loaded with pods, not quite full yet.

Chapel Hill, N. C., July 7. JULIA C. GRAVES.

TOBACCO COLUMN.

AN UNEXPECTED CONTRIBUTION TO THE WAR
AGAINST TOBACCO.

A. I. Root:—As a co-laborer in the endeavor to raise the moral standard of our race, I herewith inclose five dollars. The same I desire placed to the credit of your anti-tobacco account. I have watched with interest the responses that come to

your appeal to the people to cleanse themselves of the tobacco habit; and the number you have reached far exceeds any estimate I may have made. There is little probability that the calls upon you for "smokers" will exceed your willingness to supply; but should the demand at any time seem a tax, you might not call in vain upon the writer for a little assistance. I have the honor to be very truly your friend,

Chicago, Ill., June 11.

R. A. BURNETT.

Friend Burnett, may the Lord be praised for your kind donation—not because we need it, but because of the spirit it shows and the lesson it may teach. At present I hardly know what use to make of the \$5.00; but the Lord will unquestionably point out a way. I suppose, of course, I may have your letter for print. I want it because I feel sure it will help in the war against tobacco—the war that is to be fought, not by might nor by power, but by the influence of the Holy Spirit.

A WOMAN WHO HAS QUIT SMOKING.

Please send Mrs. Nancy Sheets a smoker. She has quit smoking her pipe. She has started in the bee-business, and would rather do without the pipe than without a smoker. If she ever commences smoking again I will pay for smoker myself.

Fredonia, Kan.

JOHN DARST.

Many thanks, friend D.; and please tell our friend Mrs. Sheets that Uncle Amos bids her God-speed in breaking away from the tobacco habit.

A YOUNG BEE-KEEPER TAKES THE TOBACCO PLEDGE.

I am now 20 years old, and have been using tobacco four years; but after reading the Tobacco Column I have decided not to use it any more. I have six colonies of bees in frame hives, and should like to have a smoker; and if you will send me one I will pay for it if I ever use tobacco again.

Goodman, Miss., May 20.

W. R. TATE.

AN UNCLE AND NEPHEW UNITE IN TAKING THE PLEDGE.

My uncle and I have been using tobacco for about three months. He has quit it, and about an hour ago I chewed my last chew; and if you deem it proper, just send us a smoker. If either of us use it in any way again we will pay you for the smoker.

Stony Point, Tenn.

A. D. DERRICK.

PAYS FOR THE SMOKER AFTER COMMENCING THE WEED, BUT HAS QUIT AGAIN.

I send you 70 cents to pay for the smoker that you sent me several years ago for stopping the use of tobacco. I have broken my promise; but I think more of my word than I do of the money, so I remit to you the amount promised. For nearly a year I have done without it, and now have no desire for it. I am very glad that, when we fail in our promises, we can begin again. I enjoy reading your Home talks in GLEANINGS, and hope you will continue in your good work.

Manchester, N. Y., May 15.

E. G. HOWLAND.

FATHER AND SON TAKING THE PLEDGE TOGETHER.

My little son and I have been smoking only since we have been keeping bees, as we thought the smoke would quell them. Since we have been reading GLEANINGS, only a stray copy now and then, I tell him we must lay aside our tobacco, as it may

seat a habit hard to leave off. For encouragement to him, send him a smoker; and we hereby bind ourselves from this date not to use tobacco in any way, shape, or form. If he or I ever go back to the habit, we will send you the price in full for the smoker.

L. B. WHITTLE.

JAMES B. WHITTLE.

Cloud's Creek, S. C., Feb. 25.

OUR HOMES.

Enter not into the path of the wicked, and go not in the way of evil men.—PROV. 4: 14.

I HAVE of late said so much in regard to temptation, and the importance of avoiding at the outset, any thing that might lead us into danger and sin, that I sometimes think I ought to be ashamed of myself; and here I am taking up the old subject *again*. It may be that it is *Satan* who whispers to me now and then that a man over fifty years old, and one who has been a professing Christian for twenty years, ought to be ashamed of himself—or, rather, ought to be ashamed of *acknowledging* that he is still tempted to do evil. Perhaps the season of the year has something to do with bringing to my mind the text I have quoted. During the month of July, most of us think more or less about some sort of recreation. Our schools are closed; many of our places of business are shut down during the heated term; some of the Sunday-schools, I am sorry to say, take a vacation; and in the absence of the pastors, church services are sometimes stopped for a time. All of us think of taking things a little easier. It is true, that those who work in the harvest-field oftentimes undergo the *severest* labor of the year; but after harvesting is done, even they usually think about picnics, excursions, Chautauqua, Lakeside, the seashore, watering places, etc. These things are all right and proper in their place. But there is something sad in the fact that at such seasons so many are ready to forget their vows to God, and vows made before their fellow-men, and stray away into old sins, and get back into old temptations. Many who have been temperate find it very hard to get past the Fourth of July. Now, to all such I would recommend the little text I have quoted: "Enter not into the *path* of the wicked." Do not even go in places they frequent. If there is any place where bad men are wont to congregate, go not there. It is sometimes urged that we should go to do them good, or go to keep down the evil. This may all be very well, if we go as missionaries, or go with that idea in view. But, beware of letting Satan deceive you. If you turn to the 4th chapter of Proverbs you will find a verse just after our text, which reads, "Avoid it, pass not by it, turn from it, pass away." If you do this, there is not very much danger. I know this by experience. But there is always danger if you *dally* with sin. Another verse, further on, reads: "For they sleep not, except they have done mischief." Many a boy, many a girl, would have been perfectly safe from temptation had they not

unwisely *chosen* dangerous places. There are streets in our great cities where it is said to be unwise for a woman or even a man, for that matter, to walk, unless it be on business. Once when staying over night in the city of New York I felt a great curiosity to just take a look at the dangerous localities. I hadn't any business there, as a matter of course; but I wanted to *see*, at least from the street, the things we have all heard so much about. Yes, I had a curiosity to see what was going on in such places in the night time. I decided that I would walk briskly, and pretend to be on urgent business, so that nobody would take any notice of me. But either I was not sharp enough, or else even a busy man is not secure from interruption. In a little time I was followed. I caught only a glimpse of the poor lost wretch who attempted to enter into conversation with me, but her voice still rings in my ear, and the hollow, mocking laugh that I heard behind me as I hurried away follows me still. Another verse reads: "They eat the bread of wickedness, and drink the wine of violence." But after the above verse comes one of such wondrous beauty, and so bright with hope, that I want to put it in right here, even if it is not in a line with my subject. It is this: "But the path of the just is as the shining light, which shineth more and more unto the perfect day."

I presume we all have this longing for something new and something different. During these July days we hunger for some sort of change. We want to lie off for a day or a week, or perhaps a month. We want to go somewhere. We want rest, and we want recreation. It is right that we should, too, dear friends, and I hope many of you who read these lines are having rest and recreation. Here in the factory we have been so busy for months past that no one has even spoken of a picnic or excursion or a holiday. Just now, however, we are glad to recompense these friends by telling them that any of them can take a vacation if they wish, providing, of course, too many do not go at once, and that they also make some arrangement for filling their post while absent. Our orders are all filled; however, we have quite a good many still coming and going daily. What shall we do for recreation? The children and even mamma almost always find a little fault with me because I always recommend some kind of *work*. For instance, I should say, "Have rest and recreation and fun in raising strawberries." Now, with a great many of you this would mean severe hard work. I am glad to note, however, that a great many of my readers look at it as I do—that is, where it is a change from their every-day toil. Why do I recommend these things? Well, because so many who start out to have a good time do not seem to have it, after all. It turns out like the words in Isaiah: "Wherefore do ye spend money for that which is not bread, and your labor for that which satisfieth not?" Perhaps some of us have had experience in that way. I wonder if I shall judge harshly of humanity when I suggest

that recreation and having a good time suggest to many something sinful. I hope it does not to you, dear reader, but I am afraid I shall have to confess that, a great many times when I feel out of sorts, and a general lack of interest in my every-day work, my thoughts are very apt to turn toward something sinful. A man who has been intemperate, when he thinks of a picnic or a hunt in the woods, or boating and fishing, instinctively turns his thoughts longingly toward some sort of stimulant to take along with the lunch. One whose besetting sin is gambling would take along a pack of cards. Perhaps neither would propose to do anything bad. One would say, "Oh! a little fun won't do any harm just at this time of year, when we are having a holiday." The other would suggest, "We will just play a little among ourselves, just for the fun of the thing, without any stakes." My friends, let me bid you read the 4th chapter of Proverbs. "Enter not into the path of the wicked, and go not into the way of evil men." I do not know where *your* besetting sin lies. I do not know just where you are weak, but it is pretty much the same. The only safe course is, "Avoid it, pass not by it; turn from it, and pass away." I have told you about our horse Meg that used to run away. Although it was years ago, everybody who handles her needs to be cautioned to keep a firm hold on the reins. Sometimes, after I have driven her for fifteen or twenty miles I think to myself, "Oh, well! she is too tired to run now. If the lines were thrown right down on the dashboard there would be no danger." Before long, however, I have been ready to change my mind. Even after she has been driven *twice* fifteen miles I have seen her start with as much strength and suddenness as if she were right fresh from the stable, or as if she had not been used for a week. And it is so with Satan and sin. Do not console yourself with the idea that you are too weak with hard work during these hot days to be in danger of evil suggestions. Do not delude yourself. Satan is on the alert, and is watching for just such opportunities. Physical weakness and exhaustion count as nothing when *Satan* has once got hold of the reins again. Before you know it, almost before you have time to say, "Lord, help," you are swept off your feet out into the stream. Keep clear of dangerous paths. Choose wisdom and not folly. Never mind if you are tired and weary. Better wear out your shoes—yes, better a thousand times wear out *yourself*, than to get back into the hands of the evil one.

Now, notwithstanding I do not take up many of the ordinary amusements and recreations, I am still one of the greatest fellows for something new and something exciting that you ever knew. If I can not have some variety in the routine of every day's duties, I am not satisfied. Nay, further: I am hardly satisfied unless I can explore some *unexplored* region, more or less, every day. As a matter of course, every little while my explorations run into Satan's domain. How can I tell? There is no difficulty, dear friends, in deciding. The

one who is constantly seeking wisdom and guidance from *on high* will always be told very quickly when he is sinning against God or against his fellow-men. Now, when my enjoyments are of that nature that make me feel even just a *little* bit guilty, this sense of guilt constantly mars the enjoyment. The little prayer I have told you of, "Lord, help," begins to ring with its warning note. When my pleasures and enjoyments are of such nature that I can freely ask God's blessing on them, it gives a new and pure sense that I can hardly explain. But you know how it is yourself. When I am out among my strawberry-plants, say at the close of the day, between sundown and dark, I often say to myself, "Thank God! thank God! There is nothing wrong or wicked in being happy with these gifts that come directly from his hand." And this reminds me of a single sentence in a letter just received from friend Terry:

Those Haverlands yielded at the rate of more than \$1000 per acre. T. B. TERRY.

Hudson, O., July 8.

Now, it is not the *money* that friend Terry is after, that makes him rejoice at this result, but it is because of the possibilities that he sees along the line where he is making discoveries. It is because he sees plainer than ever before that he has made no mistake, and that his convictions were right.

There is another line of temptations that beset and trouble and worry a great many of the friends who come to me, and it may get in and mar the enjoyment of any kind of recreation—yes, even strawberry-raising. The temptation I allude to is the one of *unwise expenditures*, or *extravagance*, if I may so term it. Some of you who read these pages may say, "Well, I am going to have my recreation as Bro. Root does, in raising strawberries." He may commence by buying a piece of ground he has no right to buy; or he may take time that belongs to his employers. He may purchase *manure* unwisely. He may finally order a *great lot* of strawberry-plants (of A. I. Root), when he could have got a *few* near home to much better advantage. If there is any class of sufferers that I feel sorry for from the bottom of my heart, it is those whom Satan tempts to pay out their money unwisely as fast as it gets into their fingers, and sometimes a little faster. Do not mar your happiness in this line, dear friends. My first experiment with strawberries, and the one I think I enjoyed the most, was in taking some old dried-up plants during a drouth in July, and giving them water until their dried-up runners revived and put out new leaves. I did most of the work between sundown and dark, so it cost little or nothing. Then I wheeled manure on a wheelbarrow from a place where it was doing no good, to make a mulch. With this start, and without buying any plants at all, I produced the finest crop of strawberries, I believe, I ever raised. Of course, I did not know what variety I had got hold of; but that did not matter very much then. Now, when you can use something for recreation and enjoyment that costs us nothing, and

does not encroach upon anybody else, you can truly rejoice. A little beginning can be made in almost all of these rural industries in just the way I have indicated; and when we are learning to love plants or domestic animals, and are led through them to look up in *wonder* and *joy* and *praise* to the great God above, we are in a measure *safe* from Satan's allurements.

I now want to refer to the text about the Holy Spirit, in my talk of June 15. I am still praying for the Holy Spirit according to the promises of Christ Jesus the Son of God; and something a little surprising in regard to this matter of temptation has come to me along this line. One who is praying for the Holy Spirit is not likely to fall into temptation; for the attitude of heart that would prompt one to pray for the Holy Spirit would be very sure to crowd out thoughts of evil. The trouble is, then, that we get into an attitude of heart where we do not *want* the Holy Spirit—where we rather excuse ourselves and turn to the pursuit of something else. In this attitude of heart we are in great danger of falling into Satan's hands. The gift of the Holy Spirit crowds out and keeps away every thing evil, and it is this that makes it the greatest of all God's gifts. We read in the first Psalm, "Blessed is the man that walketh not in the counsel of the ungodly." When we are busy with something good we are not likely to be led away by something that is evil. With the Holy Spirit in our hearts we shall be constantly prompted toward acts of kindness and acts of mercy, and these promptings should keep us so busy that we shall have no time and no taste or desire to join in with those whose works are evil. And since I have been praying for the Holy Spirit, my busy days seem to be my happy days. I greatly enjoy being what I have been mentally calling myself—a "connecting link." I do not mean the connecting link that Darwin sought for and did not find, but a connecting link in a helpful way. Were you ever out in a field with a plow or cultivator, and horse and whiffletree, but could not go on with your work because you lacked a simple connecting link? Sometimes a piece of harness is made to do duty in default of something better. A clevis, if it is on hand, makes a good connecting link; and I have often declared that I would have clevises of different sizes hung up in the tool-house, so that, when one gets lost or broken, an extra one might save time and vexation. Well, I have been happy in making myself a connecting link in the machinery of every-day life. Two men were drawing a heavy burden, during a hot July day. The burden was too heavy for them. I glanced out of the window and saw a man approaching them from an opposite direction, with a horse all harnessed, ready to hitch on to some vehicle. I remembered a whiffletree standing against a post in the tool-house. If the whiffletree could be on the spot when the horse passed the two men with their burden, the horse would do easily what they were doing with difficulty. If I should call a boy, he would not understand where the whiffletree was, and the

man with the horse would be gone. By going downstairs with a rush, and through the apiary on a run, I knew I could get the whiffletree at the appointed spot before the horse got out of hearing. Nobody was astonished to see me go downstairs as if the house was on fire, for I often do it. The bees did not sting me as I rushed among their hives, for very likely they have often seen me do it. The men looked their thanks, even if they did not say anything, as old Charley walked off with the burden easily.

Now, in our busy place of business, by keeping my ears and eyes open, I can, a great many times a day, make myself a connecting link in just that way. I presume a great many of the friends think I just *happened* to be on hand with a whiffletree, or that I just *happen* to hear the whistle of the man who drives the wagon with the berries. But there was no "happen" about it. My ears have been sharpened, I hope and believe, under the influence of that little prayer for the gift of the Holy Spirit, and it has made me more wideawake, and keener to the needs and wants of those around me. I hope. And I hope, too, it has made me kinder and more forbearing. Now, please do not, any of you, say that I am telling these things because I want to boast of what I have done. I boast not of *myself*, but of the *Holy Spirit* that is promised as a free gift to all and every one of you. Some of you are wanting to know what you can do for Christ Jesus. Some of you want to know what you can do for your fellow-men; and some are wanting to know what they can do to earn a livelihood; and others, I hope, are wanting to know what they can do to keep themselves busy, that they may not want to go into the path of the wicked, as in our text to-day. Dear friends, that promised gift of the Holy Spirit will supply all these wants. But while you are praying for it, please remember that you *can not* "enter into the path of the wicked" nor "go in the way of evil men;" for if you do, *after* such a prayer, you would not be consistent and honest; therefore, as I have said, is *prayer* a safeguard. Now, when you go off for your summer vacation, or when you go to picnics or on an excursion, or take a holiday, and you want to have a good time and a happy time, pray first for that Holy Spirit I have been telling you about, and then enter *not* into the path of the wicked, and go *not* in the way of evil men.

The above was dictated late Saturday evening. It is now Monday morning. Monday always brings a burden of cares. It seems harder, because I have been out of the harness for a little while, and it takes a little time to get the harness adjusted and the burdens fairly shouldered. Now, please do not think I am complaining. The harness is a grand and glorious one; and when I am bearing the burdens for Christ's sake, I am not only proud of them, but *happy* that I may bear them. Almost in the outset I found a grand place for making myself a connecting link, as I have been telling you. The foreman of one of the rooms sent word

that he would prefer to resign his place rather than to have "so and so" work there any longer. "So and so" declared with equal positiveness that it was by my express orders that he should go to work Monday morning in that very room. Each one was full of complaints of the other. My first impulse was to dismiss all connected with the disturbance. It is now our dull season, and we could spare half a dozen, without minding it. But I said nothing to anybody, but took a turn in the open air, and prayed for that gift of the Holy Spirit which is promised. That Spirit told me at once that I should feel very badly if I dismissed these friends with their hearts full of jealousy, fault-finding, and evil. I thanked God that I had not acted upon the impulse of the moment. One of the parties is a professor of religion, and I had a big hold on that. As I plead with him and quoted texts, his string of complaints became shorter and feebler; and he finally admitted, with tears in his eyes, that it really was the lack of Christ's spirit that brought the present trouble. His comrades were not professors; but I reminded him that it is our duty and our privilege to lead them to Christ; and yet how far—oh, how very far away we were from it!

As I caught a glimpse of the bitterness in the hearts of all concerned, it seemed to me that it would need not only a long "connecting link," but one of *mighty* strength, to unite the two parties. But, dear reader, the love of Christ can bring together the bitterest enemies the world ever knew. It can bridge over chasms that have their outgrowth in years. Satan can be routed, and the love of Christ be implanted instead, oftentimes, if even only *one* of the parties is a professing Christian. Now, then, suppose I had hastily dismissed all who were quarreling. As a part of them proposed to dismiss themselves, all I should have had to do would be to assent. I can not tell you how glad I am that I did not assent. Had I done so, the feeling of bitterness would have extended to myself; and my chance of leading them to the Savior would have been passed by, perhaps for years to come. As it is, all feel kindly toward me, and I am sure that at least *one* of them will give me a hearty co-operation in anything I propose, and, in fact, the little pleading I did for Christ Jesus has brought me nearer to that one than I have ever been before; and as I pen these words, dear reader, I rejoice and feel exceedingly happy to think of the new bond of friendship and love between myself and that one—to think of the *strong* connecting link for Christ Jesus, where there might have been only bitterness.

THE NEW WATER CURE.

SOMETHING FROM ONE OF OUR DOCTORS, AND ALSO A KIND WORD FROM THE OTHER SIDE.

BEFORE dismissing this matter, I wish to give a couple of letters selected from a large number on the subject. The first one is from one of our regular practicing physicians:

Mr. A. I. Root:—You give the doctors a punch in GLEANINGS of July 1st for being "perfectly silent on this great discovery" as you term it. Now, I think I speak the sentiment of a large majority of the medical profession when I deny the charge by saying we are not silent, but "speaking out in meeting" day and night, the world over, and because we do not parade our wares in public, and advertise in the popular journals and daily prints, and discuss "the Great Discovery," which is as old as Hippocrates, and has been used by physicians from that day down to the present, you must not conclude that we are *silent* and *disinterested* spectators, or afraid of diminished rations of "bread and butter," as Dr. Hall is pleased to insinuate, in case the "Great Discovery" comes into general use, and "doctoring" is carried on "without medicine." We report remedies and the general treatment of diseases, and special cases, to each other, through the medical journals, the only proper vehicles for such communications. "A little knowledge is dangerous;" and while you are reporting your "Great Discovery" to your 10,000 readers you should point out the pathological conditions to which it is applicable, as well as the great danger that would result from its improper use. All remedies are relative agents—relative to the pathological conditions existing—and all good remedies are dangerous if not rightly used; and this one which you extol so highly, and recommend so indiscriminately, caused the death of a lady in this city, in the convalescence of typhoid fever, although used under the direction of a skilled physician. Now, you seem to think our keeping still is at least suspicious, and would like us to appear before the public and prove our innocence to the entire satisfaction of all your readers. You have asked the question yourself, and we patiently await the verdict. Our evidence is before the world, and we submit the case without argument.

J. A. SCUDDER, M. D.

Washington, Ind., July 7.

Very good, Dr. S. I hardly need say that I believe you are right in nearly every particular. Any thing that comes up, having a tendency to spoil our faith in the family physician, tends toward danger and evil. I have, however, received so many very kind letters from those who have very great faith in Dr. Hall's remedy, that I thought best to submit one of these also:

Mr. Root:—I noticed your editorial in GLEANINGS for May 15, and I wish to say I think you have done a great wrong to perhaps hundreds of people. I will explain. If I had read your editorial before I had purchased the secret I should never have bought it, for the reason I have such confidence in your criticisms; but I have practiced the treatment, and it has saved me a great deal of sickness and money, and I would not sell it again for \$1000. You say it is well known to our doctors. If that statement is true, why did they not prescribe the same for me? I have had several doctors treat me during the last 20 years for what they called "inaction of the lower bowel," and every little while I would get bilious and have a sick spell; and the nearest anybody ever came to prescribing that treatment was one doctor who told me to take one of those five-cent glass syringes and inject a gill of cold water. Now, can you not see that there are others to whom the treatment would be just as beneficial as

it is to me, and that your editorial will for ever deprive them of that which, if they had, they would not part with for any amount of money? therefore you have done them a great wrong, saying nothing about whether you wrong Mr. Hall or not. You say Dr. Hall claims it was revealed to him by the Almighty. I can not find any such statement in the pamphlet, in the light that your editorial gives it, any more than you claimed that God revealed that spring to you there by the windmill; and I believe both of you in your finding the knowledge of the spring and the secret.

Another thing, Mr. Hall does not claim that the injection was a discovery, but that the retaining of water after having had a thorough evacuation was, and I most heartily agree with him. And even admitting that it is an old remedy, is he not a benefactor by bringing it before the public? and is it not worth \$4.00 to any family? Do you not bear witness that it is "valuable"? and would you have known it if it had not been sold for \$4.00?

And now, Bro. Root, just one thing more: Two years ago this village had an epidemic of meningitis. Four of my children had it. *Two died*, and I believe before God that this treatment would have saved my boy's life. If you are acquainted with the disease, you know the first and main thing is to get a movement of the bowels; and as they are taken with vomiting, it is impossible to give physic. Could I not with this secret have done better? In closing I will say my heart is full because I think you have done wrong, and a great wrong, to your fellow-men. I am not selling, nor interested in the sale of it, nor in Mr. Hall. ADOLPHUS NEWTON.

Norwich, N. Y., June 6.

EDITORIAL.

But the fruit of the Spirit is love, joy, peace, longsuffering, goodness, faith, meekness, temperance; against such there is no law.—GAL. 5: 22, 23.

UNTIL next issue we will pay 5c each for the April 1 and May 1, 1890, numbers of GLEANINGS.

DECLINE OF BEESWAX AND FOUNDATION.

SINCE the rush of the season is over, the price of beeswax has eased a little, and we are able to cancel the last raise of 3c. per lb. Price of beeswax will be same as on the cover of last issue. Heavy brood fdn. 45c. per lb., and at same rate for other grades.

ASTONISHED BEES.

WE clip the following from the *Country Gentleman*:

Among other things struck by lightning this summer was a bee-tree near Cuesta, Ga.; bees and honey were scattered in every direction, but the bees couldn't hit back.

ANOTHER WARNING NOTE.

IN spite of our caution on page 470, we have received two or three more samples of foul brood by mail and one large one by express. The one last mentioned came in the absence of the writer (E. R. R.), and the receiving clerk, not supposing the box contained any thing so dangerous, of course opened it. It being very hot weather, some of the honey had melted and run through, when my attention was called to it after my arrival home. I took it down in front of the boiler-arches,

carefully examined it, and found it was the genuine foul brood. Fortunately it came during a great yield of nectar, and of course there were no robbers. Had there been, we might have had a repetition of our foul-brood troubles. I tell you, friends, it is a most serious matter. Sending foul brood by mail or by express can not help placing in jeopardy any apiary within whose immediate vicinity it may come. The instructions and description of foul brood, given in our ABC of Bee Culture and in Prof. Cook's last Bulletin, are so complete and full that our friends ought to be able to properly diagnose any case of the real trouble. Bro. Newman, in the *American Bee Journal*, has likewise informed his readers, and we hope the other bee-journals, if they have not already done so, will send forth a warning note. Our friend wished us to send it to Prof. Cook, after examining it. Instead of complying with these instructions I gave it a "hiss" into the boiler-furnace. It is like sending dynamite or nitro-glycerine through the mails. While in the case of foul brood, human lives are not jeopardized, yet *human interests* are so most seriously.

Either our friend above is not a reader of a bee-journal, or else he reads them so carelessly that he overlooked the former warnings. If he had been a follower of our pages a year or so back, he could not have been mistaken as to what he had in his apiary.

Later.—After the above was in type I noticed that Bro. Jones, of the *Canadian Bee Journal*, thinks it necessary, for proper diagnosis, that samples of the infected brood be sent to the proper persons. With the clear and minute descriptions that have been given of the symptoms of the disease, I still think that a person of average intelligence could very easily diagnose his own cases.

HONEY AS FOOD.

How many times I think of Josh Billings' quaint speech—"What is the use of knowing so much, when so much that you know ain't so?" I am reminded of it just now in the confession I have to make. A short time ago I gave you my experience in using honey as food, and I was quite emphatic in saying that it gave me a headache when maple syrup would not. Well, a few days ago I took a notion to eat quite liberally of the new alfalfa honey, spoken of in last issue. Quite to my surprise I felt unusually well during the whole afternoon. Then I ate still more for supper, and good old dame Nature pronounced it tip-top and called for more. Since that I have been eating quite liberally, with the best results; and when I found that alfalfa honey agreed with me perfectly, I substituted good well-ripened basswood honey (extracted, of course), with the same results. Therefore I wish to ask my good friend Cook to let me take back at least a good deal of what I said about honey being unwholesome. In the latter experiments I ate it with good nice bread and good nice butter; and I believe that, in my former experiments, at least several times I ate honey with hot biscuit or something of that sort, and I am afraid I charged the honey with something that belonged to the hot cakes that went with it. Perhaps you think I am taking considerable space for a small matter; but it is quite a serious matter when the editor of a bee-journal says that honey is not good food, even if he does mean to say, so far as his personal experience goes. Very likely a kind of food that would at

one time induce nature to protest, might at some other time prove to be exactly the thing she wants and calls for. Shall we not all be slow in coming to positive conclusions?

SPECIAL NOTICES.

OF INTEREST TO AUSTRALIAN READERS.

Goods shipped to Australia have had the option of three routes: Across the continent to San Francisco, thence by steamer, which is the quickest and most expensive route; by steamer via New York and England, and via sailing vessel from New York direct, the last being the cheapest and also requiring the longest time, usually about five months from New York. We have just received advice of a steamer, "Prodans," to sail a month hence direct for Adelaide, Melbourne, and Sidney, and expected to make the trip one way in fifty days. We are assured that the rate will be low, less than half the cost by steamer via England, and we sincerely hope, for the benefit of our Australian correspondents, that the venture may prove successful and be continued.

EGYPTIAN ONION-SETS, CROP OF 1890, ETC.

Ours are now ready to gather, and, like the strawberry-plants, the quicker you get them into the ground the better growth they will make before winter time. Price 10 cts. per quart, or 75 cts. per peck. If wanted by mail, add 10 cts. per quart extra. We shall not be ready to send out strawberry-plants before about the first of August. During the coming fall we shall offer for sale only four kinds—Jessie, Bubach, Haverland, and Gandy. We drop the Sharpless for the Jessie, and the Jersey Queen for the Gandy. We mention this, as others may wish to know our preference among all the new sorts that are offered. The Gandy is the one, it will be remembered, that has been advertised as the "first season's" strawberry. We shall also test quite considerably the strawberry known as Michael's Early, also sometimes called Osceola. This seems to be about the best early strawberry.

COMB MOTTOES AND LETTERS IN COMB.

You can add much to the attractiveness of your fair exhibit by having the bees work out in white comb, letters forming your name or some motto. It will be the means of attracting many more eyes than would otherwise notice your display. We are again prepared to furnish letters as we did a year ago, and that you may know fully what we did agree to furnish we copy from last year's notice:

We have a full set of pattern letters to work from, and they are of such a size that three will fill an 8-section wide frame, the openings forming the letters being about $7\frac{1}{2}$ in. high and 5 in. wide. *M* and *W*, of course, are wider, and *I* narrower. The letters are of the following pattern:

FAIR, 1890.

The price will be 10 cts. per letter or figure. With thin foundation inserted, 15 cts. per letter or figure. In ordering, if you will write the letters in the order you want them, we can make 3 letters in one piece, just right to slip into a wide frame. Or if you don't happen to have a wide frame, simply tack a bar on top, to suspend it from, and hang it in the hive without a frame around it. The 4 figures, 1890, will go in a frame. To make the letters, we simply tack two $\frac{3}{4}$ -inch boards together, mark the letter, and jig it out on a scroll-saw. To put in the foundation, separate the boards, lay a sheet between, and tack them together again. We make the letters large, because the bees will work in them more readily, and they are much more conspicuous when filled.

PREMIUM OFFER.

To those intending to make an exhibit, and who will agree to distribute judiciously the circulars we will send, we will furnish free one letter or figure for each dollar's worth of goods ordered, if the order amounts to \$4.00 or more. If foundation is inserted in each letter, we will furnish 2 letters for every \$4.00 worth of goods ordered.

Will tell you more about our fair offers in next issue.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens
which they want to dispose of, we will insert notices free of
charge, as below. We do this because there is hardly value
enough to these queens to pay for buying them up and keep-
ing them in stock; and yet it is oftentimes quite an accommo-
dation to those who can not afford higher-priced ones.

Ten young hybrid Italian queens for sale at 25c
each, if you take five or more you may have them
at 20 cents each. J. H. JOHNSON.

Middaghs, Northampton Co., Pa.

33 good hybrid queens for sale raised under the
swarming impulse, 30c each, or 4 for \$1.00.

J. M. KINZIE, Rochester, Oakland Co., Mich.

I am now requeening my apiary, and will have
about 25 queens to spare, mostly Italians with just
a slight dash of black blood; any one sending pro-
visioned cages can have them at 25c for one, or 5 for
\$1.00. LUTHER PURDY, Killbuck, Holmes Co., O.

25 mismatched Italian and albino queens for 20c
each; 12 for \$2.00, or 23 for \$4.00. I guarantee safe
delivery. J. W. TAYLOR, Ozan, Ark.

50 hybrid queens for sale at 2½c each; 5 for \$1.00.
J. A. GREEN, Dayton, Ill.

Five fine hybrid queens 25c each; or the lot for
\$1.00. WILLIAMS BROS., Burdick, Porter Co., Ind.

CONVENTION NOTICES.

The Southwestern Wisconsin Bee-keepers' Affiliated Association will meet Oct. 1, 1890, in Platteville, Wis., at the residence of E. France, to commence punctually at 10 A.M., sharp. There will be a large turnout of prominent beekeepers of the State. A question-box, free to all, in which any subject you wish discussed can be presented and answered. Let every one be on hand and bring in his report for 1890, starting at spring count, or May 1. There will be blanks sent to each member for this purpose. In due time, by the secretary. Boscobel, Wis. BENJ. E. RICE, Sec'y.

HONEY COLUMN.

CITY MARKETS.

MILWAUKEE.—*Honey.*—The demand for honey is good for this season of the year. The supply of old crop is fair, equal to the demand. Can quote:

White, 1-lb. sections, choice, 13@14; white, 1-lb. sections, medium, 12@13; dark, 1-lb. sections, good, 10@11; white extracted, in bbls. and half-bbls., 7@7½; white extracted, in kegs and tin, 7½@8; dark extracted, in kegs, bbls., and tin, 6@6½. *Beeswax*, 28@30. A. V. BISHOP, Milwaukee, Wis.

COLUMBUS.—*Honey.*—Market bare of merchantable stock. The crop in our own apiary being a failure, the same being the case in the surrounding country, from which we draw our supplies at this season, shipments from a distance would meet with ready sales at 17@18 cts. for fine white clover. EARLE CLICKENGER, Columbus, O.

BOSTON.—*Honey.*—No change in honey or beeswax. BLAKE & RIPLEY, 57 Chatham St., Boston, Mass.

SAN FRANCISCO.—*Honey.*—Honey quiet. Extracted, 5@5½; comb honey, 11@12½. *Beeswax*, 21@23. SCHACHT, LEMCKE & STEINER, June 14. 16 & 18 Drum St., San Francisco, Cal.

ST. LOUIS.—*Honey.*—New crop comb, 1-lb. sections, 13½; extracted and strained, in cans, 8@9; extracted and strained, in bbls., 6½. *Beeswax*, prime, 27. Demand fair. D. G. TUTT GROCER CO., July 19. St. Louis, Mo.

DETROIT.—*Honey.*—No new honey offered, and no old left to quote. *Beeswax*, 26@27c. July 18. M. H. HUNT, Bell Branch, Mich.

WANTED.—Comb and extracted honey. State price and quantity. WALTER S. POWDER, Indianapolis, Ind.

FOR SALE.—2000 lbs. of extracted honey, in 60-lb. tin cans. Send for samples and prices. LEINIGER BROS., Douglas, O.

FOR SALE.—2500 lbs. extracted white honey, in 60-lb. cans. @\$.50 per can F. O. B. R. L. TUCKER, Nevada, Mo.

FOR SALE.—3000 lbs. comb and extracted honey, A No. 1. Address J. B. MURRAY, Ada, Ohio.

Please quote honey. Can use 2000 lbs. nice. THE DODGE GROCERY CO., Dayton, O.

KIND WORDS FROM OUR CUSTOMERS.

The bee-hives arrived all right, and we are much pleased with them. G. GARVER.
McVeytown, Pa., June 9

PROMPTNESS.

The queen ordered yesterday by telegraph was received to-day, safely. Accept my thanks for your prompt fulfillment of my order. E. E. BEWINGER.
Pittsburg, Pa., July 22, 1890.

WELL PLEASED.

I received the queen in good condition. I am well pleased with the whole transaction. Accept thanks. I am so well pleased that you will find another order accompanying this. T. J. MAWHORTER.
Wawaka, Ind., July 22, 1890.

GLEANINGS GOOD FROM COVER TO COVER.

You may continue GLEANINGS until you are told to stop, and that will be when I am unable to keep bees or earn enough to pay for it. GLEANINGS, from cover to cover, is charming for the enthusiastic apiarist, and always a welcome visitor with me. J. G. EARL.
Arden, N. Y., July 19, 1890.

GLEANINGS A GOOD INVESTMENT.

I am very much pleased with GLEANINGS, and will say that its cost has many times returned to me in the knowledge of facts contained therein. No investment I ever made returned me so much on first cost as GLEANINGS. G. WIEDERHOLD.
Yonkers, N. Y., June 20.

LIKES THE DOVETAILED HIVE.

I received the 20 Dovetailed hives the 27th, all O. K. They were packed very nice. I am well pleased with them. All who have seen them say they are the right kind of hive to use. W. H. ELLERINGTON.
Naples, N. Y., Apr. 30.

BEEES SAFELY TO SOUTH DAKOTA.

The bees you shipped me July 10th arrived on the 14th. They were just what I wanted, and in good shape. I find that it pays to order from parties that are responsible, even if it does cost a little more, as I have ordered from several parties, and got a bad muss, and from some I did not get any thing—not even my money back; yet I thought I would save express by getting them nearer home, but not so. J. W. CHAPIN.
Winfred, S. Dakota, July 15.

GLEANINGS A GOOD ADVERTISING MEDIUM.

The orders for merchandise, foundation, and labels, have been duly received. Every thing was ac-

cording to list, and, as usual, quite satisfactory. We can very heartily join our testimony to that of others, that GLEANINGS is a remunerative advertising medium. A few years of prominence before the public is necessary for a wide business. Westfield, Mass., July 11. F. H. & E. H. DEWEY.

AN A B C SCHOLAR'S EXPERIENCE.

When I was a boy in my old Kentucky blue-grass home I helped my father work with bees in the old round tree gum. The love of bees then instilled into my heart still clings to me, so I procured five colonies in old round black gum hives, and transferred them a few weeks ago into L. hives, which I made myself, and now want to combine bee-keeping on a small scale with the garden and fruit. My friend J. Gaston Catmel, a bee-keeper, has kindly loaned me some copies of GLEANINGS and your A B C of Bee Culture. I am so well pleased with these publications that I must get each of them as soon as my means will allow it. Your position in regard to tobacco, intoxicating drinks, and profanity, together with your plan of working with boys and girls and grown-up people in your business, meets my hearty approval. May God bless your work. Keep on, dear brother. There are few on earth that live and work on that line. Work on that line, and don't surrender. May we meet over there, if not in this vale of tears. M. C. BRICKEY.
Jackson, Tenn., July 2.

SUPPLY-DEALERS BEING BEHIND; THE OTHER SIDE.

Friend Root:—In looking over GLEANINGS for June 15 I notice the letter of F. F. Harrington. It pains me to read such communications, and I want to say to the readers of GLEANINGS that I have had dealings with A. I. Root for several years, and have found him one of the most prompt supply-dealers I have ordered from. His promptness in answering letters is one of the reasons I order goods shipped so far; and if any misunderstanding occurs he is always ready and willing to make it satisfactory; and what more can mortal man do? Who of us do not make mistakes? And I do hope, dear friends, we shall all try to have more charity for one another. I have felt the inconvenience of this waiting, very much; and I have been compelled to order a few goods from other dealers to last me until they do come; but I am not going to blame A. I. Root for it. He has not been sending out any price lists for some time, and is doing all in his power to fill orders, and I can not think any one is excusable for accusing him of using deception. That word means a good deal. Bro. Root, I trust you will not let unkind letters worry you very much. I presume friend H. is a stranger to you. J. T. VAN PETTEN.
Linn, Kan., June 20.

"BANNER" Years ago, when I began working with my brother, the editor of the *Review*, his apiary was called the "Banner Apiary." A large share of this apiary is still kept at the old place, where I manage it on shares. It is stocked with a fine strain of Italians, and I have been saving the best cells from the best colonies, when they swarmed, and having the queens hatched and fertilized in nuclei. These queens I offer at 75 cts. each, or three for \$2.00. No black bees near here. Can fill orders promptly, and will guarantee safe arrival. Make money orders payable at Flint, Mich. Address

SHIPPING AND SELLING HONEY.

VALUABLE HINTS FOR EVERY PRODUCER, FROM
OUR COMMISSION MEN.

As honey-producers, in a majority of cases, are about ready to dispose of their product (if indeed they have any to sell) it may not be amiss to give some practical suggestions regarding when and how to ship, and the best marketable form in order to get the best returns. This information ought to come from those who have had largest experience in the way of shipping and selling honey, and we have therefore prepared a series of questions, and sent them on to those who quote prices in our Honey Column; namely, the much-abused commission men. These fellows, with all their faults, render much and valuable service to bee-keepers, though some of our friends, we fear, think otherwise. While it is a good rule to dispose of honey at home if we can, at good prices, yet if this can not be done we must seek the aid of those who make it a business to handle honey. Our honey-men have very kindly answered the questions we ask below, and we hope our readers will take pains to read carefully the suggestions given in the replies. The questions are as follows:

1. Do you prefer to receive consignments of comb honey in single-tier or double-tier cases? and what capacity in pounds?

2. What is your opinion as to the best size of sections for selling—1-lb., 4½x4½, or a different size?

3. Do you prefer that the 1-lb. section shall contain a little less than a pound, or a little more?

4. Do any of your customers sell sections

by the piece rather than by weight? What way has your preference?

5. Do you have any difficulty in moving off dark grades of honey?

6. Would you recommend the producer to market all his dark honey in extracted form, rather than in comb?

7. What sort of package is best adapted for shipping extracted honey? What do you think of the 60-lb. square tin cans, as compared with barrels and kegs, for shipping? In short, what package do you recommend your shippers to consign you extracted honey in?

8. About what time ought comb honey to be sold, to get the best prices? What time for extracted?

9. When a consignment of comb honey comes to you in a broken-down condition, what do you do?

10. Do you think that producers realize more for their honey when shipped on commission than when sold outright?

The replies are as follows:

1. Single-tier cases, not over 30 lbs. net.

2. 4½ x 4½.

3. 1-lb. sections preferred, short weight.

4. Retailers sell by the piece, calling it a pound.

5. Dark grades, except buckwheat, move off slowly, and at low prices, comparatively, though straight buckwheat sells readily.

6. We recommend extracting all dark honey but buckwheat.

7. We prefer cheap dark grades of extracted honey in barrels or half-barrels, on account of lower cost; fine grades in new 60-lb. cans, with screw tops, or in good kegs.

8. Best time for comb honey, in the early season;

1. e., September and October; extracted, from September to February.

9. When consignments come in broken, and shippers hold a receipt signed, "In good order," *without* the claim, "Owner's risk," etc., we make claim for damage against the transportation company, in many cases.

10. Producers generally realize more when shipped on commission than when sold outright. This is the reason why the king of bee-keepers, Capt. H., ships all of his product on commission.

1-lb. sections of honey sell best in light and *showy* paper cartons. We recommend strongly, again and again, to put in every crate a sheet of corrugated or indented pasteboard. It protects the combs somewhat against breakage; and if one comb is leaking it protects all others against soiling.

New York, July 7. F. G. STROHMAYER & CO.

1. We prefer the single-tier cases, about 25 lbs. each.

2. One-pound sections.

3. Full one pound.

4. Honey in sections is generally sold by weight.

5. There are objections to dark colors, and such can be sold only at a reduced price.

6. By all means let the dark honey be extracted, as it will not sell in the comb.

7. We find extracted honey more salable in barrels and half-barrels. We would not advise 60-lb. packages of any sort. They are more expensive, and yet not desirable. We would recommend shippers to send their extracted honey in barrels or half-barrels, whichever is the more convenient to them.

8. The best time for shipping comb honey is in September or October, after the hot weather is over. It is more generally used during cold weather. Extracted honey can be shipped at all seasons of the year, as the demand is not governed so much by the weather.

9. Comb honey received in a broken or bad condition has to be sold for what it will bring, as the longer it is kept the greater the waste, and less valuable it becomes; hence the necessity of the shipper's starting it in good sound packages.

10. This can be answered only by the shipper himself. If he can realize a fair price at home, we think it safe for him to accept; but there are times and places when the producer can not find sale for his property, in which case he is compelled to find a market elsewhere. Our market is quiet to-day. Our receipts are increasing. We anticipate a good demand at remunerative prices this season.

St. Louis, July 22. D. G. TUTT GROCER CO.

1. We prefer to receive consignments in single-tier cases of from 12 to 25 lbs. weight. The 12-lb. cases meet with general favor, and always move off first. Single-tier cases are preferable, as they ship in better condition; and in case of leakage there is no bottom layer to spoil.

2. The $4\frac{1}{2} \times 4\frac{1}{2} \times 1\frac{1}{2}$ section, in our opinion, is the best size, for market use.

3. Our customers prefer a section to contain a little less than 1 lb., as they are mostly sold by the piece, and not by weight. By so doing they gain a few pounds on every case, which is quite an advantage, as the article is sold on a close margin.

5, 6. We find it difficult to move all dark grades of honey, both comb and extracted.

7. Extracted honey shipped to this market should be in cans holding 60 lbs. or less.

8. As the honey crop in this section has been a partial failure for the past few years, the same being the case this year, we find that honey placed on the market early brings the best price. Later in the season it is gathered in from different sections, causing a break in price.

9. When a consignment of honey arrives in broken-down condition we recrate it. The broken combs are placed in cans, and disposed of to the best advantage. As a usual thing, when honey arrives in that condition there is very little realized out of it. Breakage might be avoided to a great extent if shippers would be careful to pack their honey properly. We have had shipments of honey arrive with a space of $\frac{1}{4}$ of an inch between sections, causing, by continued jostling, $\frac{2}{3}$ of the sections to break down, and a leakage of $\frac{1}{2}$ or more of the honey. In most cases, when honey is properly packed, particularly in small cases, it comes through in good shape.

10. When honey arrives in good shape we think producers realize more by having it sold on commission. In addition we would suggest that shippers be careful to sort their honey, and pack the same grade together. Never mix light and dark. Always ship by freight, as it arrives in much better shape than by express. EARLE CLICKENGER.

Columbus, Ohio, July 21.

1. We prefer single-tier cases weighing from 16 to 18 lbs.

2. One-pound sections, $4\frac{1}{4} \times 4\frac{1}{4}$, sell well, as do also sections $4 \times 5\frac{1}{4}$. The latter are one inch thick, weigh a trifle less than a pound, and are generally retailed by the piece. We also have considerable demand for 5×5 sections weighing a pound and a half.

3. We prefer that the 1-lb. sections contain a little less than a pound.

4. Very many of our customers sell sections by the piece rather than by weight, and we prefer this way for retailing.

5. We have no difficulty in moving dark grades of honey.

6. We would not recommend the producer to market all his dark honey in extracted form, but only that portion that is unsalable in the comb.

7. Extracted honey sells well in barrels, half-barrels, 60-lb. square tin cans, and small pails. We would recommend large producers to use half-barrels, and small producers the smaller packages.

8. Comb honey sells best during the months of September and October. The earlier it can be placed on the market, the better. The demand for extracted does not begin much before January, and sells well during the three following months.

9. We find the best thing to do with a consignment of broken honey is to offer it somewhat below the market price, and sell as soon as possible. There are always buyers for such honey, and it does not pay to overhaul damaged stock.

10. We think producers, as a rule, realize more from honey placed on commission with firms that make a specialty of selling honey than by selling outright, for the reason that the party buying outright must assume the risk of a possible decline in prices, and on that account can not pay full market price at time of purchase. We seldom have any trouble from broken honey when shipped by

freight, but we rarely receive a consignment by express that is not more or less damaged; besides, freight rates are much lower than express. Consigners should seek to keep the cases as clean and bright as possible, therefore avoid marking with brush and paint. Small stencil or rubber stamps will answer every purpose. We advise glassing one side of case only, and not the sections.

Albany, N. Y., July 9. CHAS. MCCULLOCH & CO.

1. We prefer comb honey in single tiers, twelve frames to case, weight $10\frac{1}{2}$ to 12 lbs.

2. The best size of sections to show comb honey, we think, is $5\frac{1}{2} \times 4\frac{3}{8}$ by $1\frac{1}{2}$ thick.

3. We prefer light weight, but only from $1\frac{1}{2}$ to full weight in the 12-lb. cases.

4. Most of the retail trade sell comb honey by the section.

5. We never have had any trouble in moving dark comb honey.

6. We would recommend extracting half of the dark honey.

7. We certainly recommend the screw-top 60-lb. square can, shipped in cases of two cans to the case. It all has to be put in this shape to sell in our market, except very dark honey.

8. Producers of honey, like producers of grain, must use their own judgment in moving their crops. Comb honey is sold every day in the year. As soon as the new crop comes in we always find the farmer and small bee-man selling their honey at very low prices, some years supplying the trade until October. After that time honey-dealers govern prices to a certain extent. If a number of shippers want honey sold quick, and every shipper is forcing sales at the time, this compels receivers to keep honey down in order to move stocks.

9. When a consignment of comb honey is received in bad order, we have our man go through the consignment and take out all unbroken comb and re-pack the same. The broken comb is then sold.

10. If a producer has a home trade for his honey, and time to sell the same, he may do better than shipping; otherwise a good commission man that makes a specialty of honey can sell his crop to better advantage than the producer. All comb honey should be shipped where it is to be sold, before freezing weather. It saves the shipper breakage, and the sellers the trouble of repacking, as comb honey shipped in cold weather is almost always received in bad order.

HAMBLIN & BEARSS.

Kansas City, Mo., July 12.

1. We prefer single-tier cases with a capacity of 20 or 25 lbs., it does not matter which.

2. We prefer, for one-pound sections, $4\frac{1}{2} \times 4\frac{1}{4}$ size.

3. We prefer that one-pound sections shall weigh 15 ounces rather than 17.

4. Most of our customers prefer to sell honey by the piece rather than by weight. Our preference, for our customers' sake, is that the weight be so that they can do this. We, of course, are obliged to sell by weight.

5. We have very great difficulty in moving off a dark grade of honey. Boston is the poorest market in the country for off-grade honey.

6. We would certainly recommend the producer to market his dark honey in the extracted form.

7. We prefer the 60-lb. square tin cans to any thing else, there being two 60-lb. cans in a case. We

receive a great deal of honey from Florida in kegs and barrels, but prefer the tin cans.

8. Comb honey ought to be sent to market about September 1, and from that on through the season. Extracted, about Oct. 1.

9. When a consignment of comb honey comes in in a broken-down condition, we find some restaurant man who will cut the combs out and sell them from a platter, but we have very hard work, and rarely get over 8 to 10 cts. per lb. for the honey, and never can collect any damage from the transportation company.

10. This is a hard question, especially for a commission man, to answer; and we think it best for the producer to draw his own conclusions from his experience. We have a great many letters from shippers, expressing their perfect satisfaction with the way and manner and prices they have received for their shipments of honey to us. We have had some people who have written us they could have realized more if they had sold their honey at home. We can only say that, after fifteen years of close attention to the honey business, we turn away five times as much honey as we receive, it always being our policy to check all consignments that we do not think we can handle to advantage, preferring to please our shippers rather than to secure a large quantity of honey and cut prices. We feel very sure that those who have shipped to us believe that they can do better than to sell their honey. There has been a tendency of late years to rush honey to the market in the early part of September. This always demoralizes prices; and receivers, in their anxiety to sell, put honey lower than there is any necessity for it to be sold.

Boston, Mass., July 7.

BLAKE & RIPLEY.

1. In general we prefer consignments of comb honey to come in single-tier cases; yet when properly packed, the double-tier case is usually preferred by the retail dealer, as honey shows up to better advantage, and carries, or bears transportation, equally well.

2. Sections $4\frac{1}{2} \times 4\frac{1}{4}$ we think most desirable for 1-lb. combs.

3. We should like the section to contain exactly one pound of honey. Perhaps scant is better than over, as the frame is too full, and dealers lose the overweight in many instances.

4. Where the special advantage to the retailer exists in having sections so uniform in weight that they can be sold at so much per frame.

5. There is a very limited demand for dark comb honey, and it seems to us that only those who have worked up or secured a trade for it should put it on the market unless they can afford to have it sell at 3 to 5 cts. per pound below the white in same shape. Extracting is, to our mind, the best way to secure good value for dark honey, it varying in price from one to two cents below white. A good demand is also found for it, especially a choice article, such as well-ripened buckwheat, for which we have a line of customers.

6. The most popular packages in this market are barrels containing 300 to 500 lbs., and the square tin can, which ought to contain just 60 lbs. of honey. These packages meet the wants of dealers who buy of the commission merchant or jobber. Kegs are too light, and honey soaks through them. As to which of the two packages to use, we would invariably give the tin preference, as dealers who

use barrels will take tins when barrels can not be obtained; but it is more difficult to get the other class to take barrels in lieu of tins. Yet if the tins cost half a cent per pound more than the barrels, use the barrel.

7. Our experience would point to the four closing months of the calendar year, or middle of August to middle of December, as the best months in which to sell honey, both comb and extracted; but, please remember we do not say that *that is the time to sell*, for circumstances beyond our control, and our general inability to read the future, warn us that all commercial rules are subject to change. The highest prices obtained by us in an experience of 16 years were in February and April, 1879. The lowest was about the same time in 1887.

8. Sell it as soon after arrival as possible. We do not re-case nor change from original package.

9. Sometimes one, and again the other. Circumstances existing at the time should determine the matter.

10. The subject has been quite exhaustively treated by Mr. C. F. Muth, in your issue of June 15, and we agree with him in the main details of preparation, etc., of honey for the market. As the form of package he finds necessary in his method of disposing of honey is fully explained, and the reason therefor given, no comment is needed. The one-pound section for comb honey, and the tin can and barrel before described, are at present the popular packages here.

R. A. BURNETT.

Chicago, Ill., July 12.

Yours of July 5th is received. We will try to answer your questions as near as we know how. Before commencing, we should like to say that we think the questions asked are very important, both to producers and dealers, especially those pertaining to getting honey ready for market, grading, and style of packages. If all bee-keepers could realize the importance of putting up their honey in merchantable shape they would realize much better prices and quicker sales. There is nothing better than a whitewood package for comb honey; one side glass front is sufficient; and be very careful that the contents of the case compare favorably with the row of sections that is exposed.

1. We prefer the single-tier cases, either 12 or 24 sections, weighing about 11 to 22 lbs. respectively.

2. We like the 5 by 4 $\frac{1}{8}$ and 1 $\frac{1}{4}$ thick section best. It shows a larger surface of the comb than a 4 $\frac{1}{4}$ by 4 $\frac{1}{4}$ does.

3. As the one-pound sections can not be made to weigh exactly a pound, we prefer they weigh a little less.

4. The most of our customers sell more honey by the section than they do by the pound. We should prefer to sell it by the pound.

5. We have considerable difficulty in disposing of dark comb honey, even at low prices.

6. We would recommend that at least fifty per cent of the very dark comb honey be extracted.

7. The very best package for shipping white and amber extracted honey in is the five-gallon screw-top tin can, two cans inclosed in a wooden case. Ship the very dark honey in kegs and barrels.

8. We can not say when is just the best time to sell comb or extracted honey in order to realize the best prices; but we would advise early shipments, as honey is much less liable to be broken down while in transit when shipped in warm weather

than in cold. The early shipments of comb honey generally bring the best prices, but only in a small way. Our best trade for both comb and extracted honey commences with cool weather, and continues about the same through the season. Very little extracted honey is sold until cool weather.

9. When a consignment of comb honey comes to us in a broken down condition we immediately have it looked over, all the perfect sections selected, put back in the cases, and the broken comb sold to the first customer, generally realizing about half price for it. The next thing we do is to present a bill of damages to the railroad or express company for the loss.

10. As to whether producers realize more for their honey when shipped on commission or sold right out is a rather delicate question for a commission merchant to answer; but we with pleasure refer to our numerous patrons who have consigned honey to us the past season. They will bear us out in saying that they realized more for their honey than they would have done had they (if they could) sold right out. Some producers get in a great hurry to realize from their crop; and if they don't find a customer just when they want to sell, and at the price they ask, they become uneasy for fear they will not be able to dispose of their honey. The very worst competition we had last season originated with this class of bee-keepers. We would advise them to ship their honey to some commission merchant, and give him time to dispose of it. He makes it a business to find the best market, thereby realizing the best prices for his shipper, and making him happy.

Kansas City, Mo.

CLEMONS, MASON & CO.

The replies given by commission men will in every case be found exceedingly valuable, and we hope all honey-producers will take the time to read this whole subject thoroughly. By way of a summary we note the first question, that the single-tier case is invariably preferred, the capacity being anywhere from 12 to 24 lbs.

(2) The 4 $\frac{1}{2}$ sections are in most cases recommended; and,

(3) Light weight rather than overweight is preferred, because

(4) The most of the retail trade sell comb honey by the section. We must confess that we are a little surprised at the replies to 3 and 4. Our customers are, for some reason or other, beginning to demand 4 $\frac{1}{2}$ sections a little less in width than the regular 1 $\frac{1}{2}$. In fact, during the past season we have supplied a very large trade on 1 $\frac{1}{2}$, and we propose next year to make the 1 $\frac{1}{2}$ section our standard, rather than the 1 $\frac{1}{2}$ —not only because bee-keepers demand it, but because commission men recommend underweight rather than overweight. Right here a wrong may be involved; but if the retail dealers distinctly state that their sections are sold by the *piece* and not by the *pound*, and the customer so understands it, then there is nothing wrong nor dishonest about it, any more more than there is in selling apples and oranges by the piece. Still again, most people are better satisfied in their conscience to buy a luxury providing it costs a little less than they anticipated; but if it *exceeds* the price which they have fixed in their mind as the limit of what their purse will

stand, they will rarely buy. For instance, comb honey is quoted at 20 cts. per lb. A customer asks his dealer the price of this or that section of honey. If he says 18 cts., the honey is sold; if 22 cts. is asked, the customer refuses to buy.

(5) We are surprised that so many of the commission men say they have no trouble in moving off the dark honeys.

(6) We note that most of them prefer to sell dark honey in extracted form rather than in the comb; and they advise the producer to extract most of his dark honey, if he wishes to sell it.

(7) It is surprising to note how popular the 60-lb. square tin can is for shipping extracted honey. Only two—and one of these very emphatically—prefer barrels instead of the square cans. The latter costs about half a cent a pound, and new barrels can be had for about a quarter of a cent. One of the dealers says that, if barrels cost half a cent more than the tin, use the barrels; but otherwise, he says, use the tin. After all, it seems that there is only a quarter of a cent in favor of the barrels; and as commission men generally prefer the square cans, producers may all gather a good hint here.

(8) The best time to move off comb honey is some time in the fall—it may be early or late. A good deal depends on circumstances and the judgment of the seller.

(9) We have had honey come to us in a broken-down condition; and knowing that our commission men must have had similar experiences we are greatly interested in reading their replies. We have been in the habit of sorting it over and wiping off soiled and sticky sections, but it takes a good deal of time. Blake & Ripley suggest a very sensible method of disposing of it—getting restaurant-keepers to take it at a reduced price. Chas. McCullough & Co. do not think it pays to overhaul it, and they remark that there are buyers who will always take it.

(10) We knew that this question would be a hard one for commission men to answer; but their replies seem candid, and we have no doubt but there are many times when honey on commission will bring more than when sold outright. In the latter case there is an immediate and certain return, while in the former there is some risk. It is true, that when honey is bought outright the buyer must assume all risk of fluctuations in prices; and to be on the safe side he will naturally buy as low as possible. If honey is sold on commission, both parties are interested in getting as good a return as possible, though we know *sometimes* the producer is dissatisfied with the returns. If he could put himself in the position of the commission man perhaps he would think more charitably of his neighbor.

JONES VS. BROWN, AGAIN.

THE LEGAL ASPECT OF THE CASE.

I HAVE been very much interested in the controversy over the question of the responsibility of the above parties as stated in the contract, and I differ entirely from Mr. Caldwell, Mrs. Harrison, and others. In reading the contract it reads to me like

this: Jones has let 100 (number not given) stands of bees to Brown, each to share the *profits* alike. Now, then, let us suppose that A. I. Root agrees to let W. S. Fultz have 100 stands of bees for the season of 1890, Fultz to take care of them and to share the profits with A. I. Root, and the increase is 100 stands of bees during the season. Now, how many stands of bees will belong to A. I. Root, and how many to W. S. Fultz? Evidently, A. I. Root will want the original 100 and half the increase, which would make his share of the bees 150 stands, and W. S. Fultz would have only 50 stands.

Now, if those bees were lost during the following winter, the loss of the increase, which was all that was owned in common, should be borne by both parties alike; but the original 100 stands were the property of A. I. Root, and he should stand the loss on them. According to the contract as stated in GLEANINGS, it is evident that, when Jones and Brown dissolve partnership, Jones will want his original 100 stands of bees, or all of them that will be alive at the time, and also half the increase. Then the proposition of Mr. Caldwell, in last GLEANINGS, that they are both equal owners in the apiary, is not correct. Brown is not part owner in any thing but the profits. W. S. FULTZ.

Muscataine, Ia., July 8.

When doctors disagree, who shall decide? It seems to me, friends, that keeping bees on shares is a complicated way of doing business, at the best. Why not rent them for a certain sum of money, to be paid in time, whether the season be good or bad? But even then we should have to meet the question of returning the bees in as good order as they were received.

GETTING THE BEES OUT OF THE SECTIONS.

DOOLITTLE GIVES A DISCOURAGING REPORT OF THE HORIZONTAL BEE-ESCAPES.

As the time for taking off the surplus honey is at hand, perhaps a few words regarding getting the bees out of the sections will not be amiss. The most common way of doing this in years gone by, and, surprising as it may appear, quite common yet in some places even at the present time, was to go to the hive and slide a piece of tin between the communications of the hive and sections, when they are removed; or else smoke is used to drive the bees from these openings, when, in either case, the honey is carried to a room having all but one window darkened, where it is left for the bees to collect on this window, when they are put outdoors by reversing the sash, or otherwise. The latter plan, where smoke is used, will do much better than the former; for with the tin, many bees are cut in twain and otherwise mutilated, thereby making the colony very cross, besides being a very cruel mode of procedure. I hope that no one in the future will persist in such a way of taking off honey.

Some use a barrel or bee-tent to set the honey in, instead of the room, putting a cloth over the barrel for the bees to collect upon, when it is turned over as often as the bees collect upon it, thus setting the bees free. With the tent a hole is left in the top for the bees to go out through. This latter is preferable to the room, providing the barrel or tent is left

in the apiary near where the honey is taken; for in this case many of the young bees will find their hives, while they would not if carried to the room. Some of our eastern bee-keepers have bee-escapes on the hoods or caps to their hives, the same being a cone-shaped piece of wire cloth which is placed over a hole in the cover to the hive. At the point of this cone is a hole large enough to admit a bee, which point stands out from the hive. The honey is now separated from the main hive, and communication with it shut off, while the passageways to the sections are left open. The cover is now put on, which allows no place for the bees to get out, except through the bee-escapes. The bees now commence to leave the sections, going out through the escapes, while no robber bees can get at the honey, because they do not know enough to go out to the point of the cone-shaped wire cloth, but keep trying to get in near the base, where the fragrance of the honey is the strongest. In a day or two the honey is gathered up free of bees. When I heard Mr. Manum tell of this process at a bee-convention, I at once fell in love with it, especially as he told of taking off double the amount of honey in a given length of time that it was possible for me to do. The only drawback there is to it, and the one which is applicable to all plans where the bees are removed from the hive, is, that very many young bees are taken with the honey, too young to get back again, while the queen is sometimes carried away, unless a queen-excluder is used, which in either case results in quite a loss, especially if the queen should happen to be in the sections. Again, the bees will always fill themselves with honey when thus removed; and in doing so they often make the nice combs quite unsightly by their gnawing the cappings to the cells. For the above reasons I prefer to proceed as follows, so as to leave all bees in the hive where they belong, and save the harm to the combs. I go to the hive, quietly remove the cover and one of the outside boards to the section case on the side next to me, when a few puffs of smoke are given to drive the bees off the face side of the combs. I next go to the opposite side of the hive, take off the board there also, and treat that side the same as the first. I now point the nozzle of the smoker to each of the little holes the bees always leave in the upper corners of the sections, when the smoker is worked vigorously, say two or three puffs at each hole. The same is done on the other side, using force enough with the smoker to drive the smoke clear through the sections from one side to the other. Now wait a moment or so, to give the bees time enough to run down into the hive below, when the sections are taken off nearly or entirely free from bees, and are ready to be stored away as soon as off, just where they are wanted. Should a very few bees stick to them they will be old bees, and when they fly to the window of the honey-room they can be let out and will always find their way back to the hive. Caution should be taken not to wait too long after the smoke has been blown through the holes, especially when honey is not coming in; for if we do, a reaction will take place, when the bees will run back into the sections almost as lively as they went out, where they will stick till they have filled themselves with honey, in spite of smoke or any thing else. When I first saw the horizontal bee-escapes which were to be used in the honey-board the past winter, I had great hopes for them in ridding our sections

of bees, and allowing them to go right down into the hive where they belonged, so that, without danger to either queen or young bees, we might take our honey from the hives with little labor, and free from bees; but I am informed that those horizontal bee-escapes worked far better on paper than they now do when they come to be used on the hives. One of the inventors of these escapes writes me that he is disappointed with them, on account of their not doing what was expected of them. So far our season for honey has proved almost a failure, so I have had no chance to give them even a trial. I hope, if they are not already what they ought to be, that some inventive genius may find out where the trouble is, and give us an escape that can be placed under a case of sections or an extracting super at night, and rid it of bees before morning.

G. M. DOOLITTLE.

Borodino, N. Y., July 17.

Friend D., I am very sorry indeed to hear that you have succeeded no better with the horizontal bee-escapes. At the time so much was said about them I was a little fearful that it would turn out as you say. Perhaps, however, others have succeeded better. Friends, will you please give us your experience, especially in using the horizontal bee-escape to get the bees off from your comb honey?

KEENEY'S COMB-SPACER

A DEVICE TO GET RID OF BURR-COMBS, THICK TOP-BARS, AND HONEY-BOARDS.

I THINK it was Josh Billings who asked the question, "What's the use of learning so much, when half you learn ain't so?" I have thought of it often during the last year, when reading the different articles in bee-periodicals upon the subjects of burr-combs, sagging top-bars, thick top-bars, beveled top-bars, with many devices illustrated to prevent them. Ah me! how well I know that many things for use in the apiary are perfect in theory, but practically are total failures. No subjects in apianian work have I given so much study to, as properly and accurately spacing my combs, preventing burr-combs and sagging top-bars, and I am happy to say I am master of the situation, and my frames are as free from burr-combs (except when sections are on) as when you ship them from the factory. With my spacing-device, bees winter better, come out stronger in spring, and, as a practical test, every other hive to the number of fifty, for two years, the spacers were left out; and those with it in swarmed 16 days the earliest, on an average, through the apiary, showing they were warmer, and bred up much faster—fully 40 per cent. Bees can be moved to and from out-apiaries, to and from cellar, or about the yard, without a frame slipping or shucking a particle. It is applicable to any kind or size of movable-frame hive, with combs wired as described in GLEANINGS for May 15th. Every comb will be as even and true as so many boards. Loafing-places for from 100 to 1000 bees will be closed. Any frame in the apiary will exactly fit the place of any other frame, no matter from what hive taken, making them all interchangeable, so desirable to every apiarist. The spacers can be taken out or put in in half a minute, and they do not cost 5 cents per hive. I have fully tested them two years with pride, pleasure, and profit. I use a hive similar in

size to your eight-frame Dovetailed, my frames being $\frac{3}{8}$ thick by $\frac{3}{8}$ wide, top, ends, and bottom-bars. These in the hive evenly spaced, leave 7 spaces between the frames, $\frac{3}{8}$ inch wide, with two spaces back of the outside combs, just half that width. Now get 7 strips $\frac{3}{8}$ inch thick, scant $\frac{1}{16}$ inch wide, and the length of your top-bar, also two strips half the width gotten out, and put them in those spaces; clean off from your old frames burr-combs, side and top; and if you have bulged comb, shave it off for that spacing, and you will find that all future comb-building will be in exact keeping with that scant $\frac{1}{16}$ -inch spacing. It works perfectly; and if any practical apiarist will give it a trial, and can find any fault with it, I should like to have him tell what it is, in GLEANINGS. E. D. KEENEY.

Arcade, N. Y.

If I understand your spacing-device it is simply a series of strips of wood wide enough and long enough so as to close entirely the spaces between the frames. Of course, there will be no burr-combs because the bees can not gain access to the tops of the frames the spacers are on. Those spacers must be removed every time you put on sections or an extracting-super. I doubt very much whether such an arrangement will be tolerated by bee-keepers in general, for you yourself say that there are no burr-combs except when the sections are on, and that is just the *very* time when burr-combs are built, and when we don't want them. When honey is not coming in they are not built, and so your spacers will do no good except to hold your frames at fixed distances. In fact, friend K., we do not see that you get rid of the burr-combs at all.—Your method of wiring is working nicely, and it will probably supersede all other methods for new frames in the near future.

DADANT'S EXTRA-THIN FOUNDATION STRETCHING.

THE RIGHT AND WRONG WAY TO PUT FOUNDATION INTO SECTIONS.

I am using Dadant's extra-thin comb foundation in the standard one-pound section, but have to trim every piece, as the bees bulge it if used full size. Now, if this is always the case why do they not make it narrower and save waste? Can you mention this in GLEANINGS? I should like to know what others think about it. Bees are booming on basswood now. It opened here July 4.

HARRY LATHROP.

Browntown, Wis., July 10, 1890.

We sent the above to Chas. Dadant & Son, who reply:

We think the main trouble lies in the foundation not being properly hung. It should hang thus: or

it may be that the foundation was too fresh when used, for we notice that the softness of the fresh sheets, which makes them more malleable for the bees, also helps them to sag more readily. Most of our customers use foundation for sections 4 inches wide, and we have but very few complaints of its

being too wide; we think this is due to the fact that the most of them do not use full sheets, but only three-cornered pieces or narrow strips running the full length of the section. We prefer to use sheets about $4\frac{1}{2}$ inches wide, and cut them in two so as to make a little over two inches in depth. This allows of sagging whenever there is any in the extra-thin foundation. We expected to hear of more sagging this year than other seasons, owing to the exceedingly hot weather of the month of June, but so far we have not had any complaints. We should like to hear from others. We cut our foundation any size wanted. DADANT & SON.

Hamilton, Ill., July 19, 1890.

The point you make, friend D., is referred to by Cheshire in his work, and we are glad the matter has come up as it has, for the opportunity is presented of instructing the users of foundation respecting the right and wrong way of putting foundation into sections. When it is fastened into sections as shown in the engraving, the downward pulling is all on perpendicular lines. When it is put in the other way, the cell-walls running upward are like a rail fence, or thus: If there is any stretching, this rail fence, as it were, straightens out a little. All our L. foundation is made with the cells so as to hang to the top-bar as shown in the engraving below. Our thin surplus, when it comes out of the mill, is in long strips, four inches wide. If pieces two inches wide are cut off the end, and fastened the long way to the top of the sections they will be suspended the wrong way. If, however, these strips be cut into squares, and then divided the other way, the foundation, when put into the sections, will hang right. There is only one way to get our brood-foundation into brood-frames; and that is, with the cells hanging right as shown below. We have no doubt but that Mr. Dadant makes his foundation in the same way.

After dictating the above I went down into the wax-room to test the relative strength of foundation fastened in the two ways. I took a strip of our thin surplus, 4 in. wide and about 17 long. This I cut into squares. Now, then, I welded together two of the pieces so that one side and one end lapped together. The welding was accomplished simply by pressing the lapped ends so they were, so to speak, firmly fastened. After warming the strips a little and putting the ends between a couple of grippers, I pulled to see which half of the foundation would stretch first. Of course, I expected that the foundation as shown in the cut opposite would stand the greater strain; but in this I was disappointed. I could detect no appreciable difference, after many trials, in the strength of either. Possibly in the hive, when the comb is drawn out, there may be a difference. Theoretically, the facts as stated above ought to be true. Have any of our readers tested this matter in the hive—that is, by making comparative tests by putting sections into the super with foundation fastened both the right and the wrong way? I know that Cheshire and the Dadants mention this in their works. Perhaps the Dadants can give us a little more light on the subject. E. R.

A SMALL THIRD SWARM.

REPRESENTATIONS OF THINGS TRUE TO NATURE.

If there is one thing above another with which we have taken particular pains, it is that all our engravings supposed to repre-

ject which they so poorly try to show! Yet it is nevertheless a fact that there is not a real good engraving of a queen-bee, although we think we have one in the A B C book that is fairly lifelike. In the accompanying engraving our artist has succeeded

A LITTLE SWARM OF BEES, JUST AS THEY LOOK AND ACT.

sent nature in any of its phases shall be true to life. How provoking it is that there are so many engravings of queen-bees that look as much like a beetle as they do the real ob-

admirably in showing a small third swarm. Most of our readers will instinctively recognize something familiar in the pretty little scene. While the individual bees

themselves are not exactly typical Italians, yet the cluster itself, the position of the wings, and the manner in which they are hanging together, to say the least, is real and lifelike. I wish to call particular attention to the bee on the extreme end of the broken twig on which the bees are clustering. Every bee-keeper will recognize something in that little individual, strikingly natural. The bees on the wing are not as true to nature as they might be in some cases, but they are very good. It does not take a great stretch of the imagination to think of this as a third swarm, possibly having a virgin queen somewhere in the outer edges of the cluster. Naturally enough, they have clustered on the end of a little twig of a tree so highly prized by the bee-keeper; namely, basswood—or, as some of our friends term it, the linden. Not more natural or more true to nature is the cluster of bees, than the basswood leaves. See! Here and there is a leaf with torn edges. How natural! Yes, and just a little beneath the cluster is a basswood blossom. These facts would show that the engraver had some idea of the eternal fitness of things when he made a little swarm come out and alight on a basswood limb just when such a swarm might be expected—that is, when basswood was evidently in its height, as indicated by the blossom shown a little below, at the left of the cluster.

The swarm was so small as to be unnoticed by the apiarist; but his wife has seen it, and, tugging him by the arm, points to the twig twenty or thirty feet, perhaps, above the ground. The swarming-device is handy, and his assistant has ready at hand one of the indispensables of the apiarist—a ladder. The little swarm is not worth much, but then they are evidently pure Italians, and he will make a nucleus of them. Off in the distance is a well-kept apiary; and at the right, a beautiful home. Whether these are all adjuncts of one establishment, our silent engraver will not tell us.

By way of explanation we may as well say that our artist having run across a beautiful print, evidently the handiwork of a German engraver, forwarded the same to us. We were so struck with its natural, lifelike appearance, that we returned it to him with instructions to engrave it as faithfully as he could. The original artist was evidently a bee-keeper, for how could he have made the cluster and the basswood leaves so lifelike if he were not? Our engraver who reproduced it, with some slight suggestions from ourselves, is also a bee-keeper, and the engraving attests how well the work was done.

VOLITION OF THE QUEEN IN EGG-LAYING.

DR. MILLER ARGUES FOR THE COMPRESSION THEORY.

I THINK it was Quinby, supported by Wagner, who advanced the idea that a queen lays worker eggs in worker-cells because of the mechanical compression in the smaller cell; and in the larger drone-cell, there being no compression, the egg is left unimpregnated. But the reply was made, that

eggs are often laid when the bees are building comb, in worker-cells so shallow that there can be no compression, and impregnated eggs are laid in queen-cells, which are still more roomy than drone-cells. Cheshire ridicules Quinby's idea as "a bold guess made long ago by an American apiarist of just repute, though but little acquainted with scientific matters." But Cheshire does not very distinctly state what he does believe. Indeed, it is a little difficult to tell just what is believed by the authors of our bee-works, for most of them speak in a rather vague way. A. I. Root, an author not given to vagueness, says in his A B C: "I can not but conclude that the queen knows when an egg will produce a drone, and knows just what 'wires to pull' to have every egg laid in a drone-cell produce a drone. I think it very likely the workers have something to do with this matter, but I have never been able to make out by what means they signify to the queen that some eggs in drone-cells or even in queen-cells would be desirable."

Dzierzon says: "We must, in any case, assume that the queen possesses the instinctive power to lay fertilized eggs in small cells and unfertilized eggs in large cells," while his English translator, C. N. Abbott, advances the suggestion that internal pressure has something to do with it, and "that the accumulation of eggs in the ovaries enlarges them and causes sufficient pressure to secure their fertilization as they pass the spermatheca." The revised Langstroth, while rejecting the compression theory, says: "Yet it is very difficult to admit that the queen is endowed with a faculty that no other animal possesses, that of knowing and deciding the sex of her progeny beforehand. It seems to us that she must be guided by her instinct."

Prof. Cook is not vague at all, but distinctly gives his belief that the queen controls the whole matter by an act of the will. He strongly fortifies his position by saying, "The Baron de Berlepsch has fully decided the matter. He has shown that old drone-cells are as small as new worker-cells, and yet each harbors its own brood." Prof. Cook further argues: "What gives added force to this view is the fact that other bees, wasps, and ants, exercise the same volition, and can have no aid from cell-pressure, as all the eggs are laid in receptacles of the same size."

In the face of all that has been said on the other side, it may seem presumptuous to attempt any defense of the old theory of Wagner and Quinby, that compression of the queen's abdomen decides the sex of the egg as it is laid in the cell. Still, I suppose I may raise the question whether it has not as much show of reason as any later theory. The sweeping objection to the compression theory is, that impregnated eggs are laid in worker-cells when the cell is barely commenced, "so that pressure can not be exerted," says Cheshire—"in which no compression can take place," says Dadant—"where there could be no pressure," says Cook. Is there not an entire misapprehension here? Surely Wagner and Quinby could not have meant that the diameter of the worker-cell was less than the diameter of the queen's abdomen, and that the abdomen had to be compressed each time into smaller dimensions to allow it to enter the cell. Is it not reasonable that the different position that must be taken in the smaller cell causes compression? Did you never notice the small boy who has been in-

dulging too freely in green fruits? He finds relief in compression of the abdomen, which he secures by simply bending forward. When the queen lays in a worker-cell, she bends into something like a right angle. May not that position have a mechanical effect in some way to secure the impregnation of the egg? When she lays in a drone-cell her position must be different, for the cell is deeper and wider. In the Revised Langstroth it is suggested, "It is possible that the width of the cells and the position of her legs when laying in drone-cells prevents the action of the muscles of her spermatheca."

It is not impossible that exactly the same compression may be caused in a shallow cell barely commenced as in one full depth. "If an egg is laid in a shallow cell, does not the queen bend into just as sharp an angle as if the cell were full depth? and is she not bent the same way in laying in a queen-cell? for I think she never lays in queen-cells of full depth. But, how about laying in incipient drone-cells? Does she lay in drone-cells less than full-depth? If so, might not the width, as suggested by Dadant, have a mechanical effect? But if the width makes drone eggs, then the greater width of the queen-cells ought to make the eggs droner still. I don't know what reply can be made to that, unless it be that we know very little about it, only that in some way the peculiar position essential for impregnation may be secured both in the worker and queen, but not in the drone cell.

Prof. Cook presents an argument that at first sight appears unanswerable. He says: "What gives added force to this view [the volition of the queen] is the fact that other bees, wasps, and ants, exercise the same volition, and can have no aid from cell-pressure, as all the eggs are laid in receptacles of the same size."

But, do they exercise the "same volition"? That word "same" is begging the question. Do they exercise any volition? Even if the receptacles are of the same size, and if it is fully proven that there is no compression of any kind, does that prove that there is any volition? The common fowl lays eggs of both sexes in the same receptacle; but has she any volition in the matter? Of course, I know that the impregnation is different in the two cases; but is volition proven in one case any more than in the other? If the answer is, that for any thing we know there may be some volition in the case of the fowl, then, I ask, is there any volition in the case of the human race? And now I fancy I see that good-natured smile on the face of the professor as he asks, "Do you think, now, really, that all the force is taken out of my argument?" Candidly, I don't, professor. I confess it leaves it rather bad for the compression theory, but, just as much, it leaves your volition theory "not proven."

"The queen sometimes lays worker eggs in drone-cells." Does she? In regular drone-cells? I beg your pardon. As A. I. Root says in the A B C, "The mouth of the cells will be contracted with wax," and I think no worker egg is ever laid in a drone-cell without the cell being first cut down in depth, and the diameter of its mouth contracted. Dadant says: "This contraction of the cell-mouth seems indispensable to enable the queen to put in motion the muscles of her spermatheca."

Now comes Prof. Cook's clincher. He says the Baron of Berlepsch has fully decided the matter. "He has shown that old drone-cells are as small as

new worker-cells, and yet each harbors its own brood." Now, if that proves any thing doesn't it prove too much? If the queen by her volition puts a worker egg in every cell of small size, certainly she would do so here where she finds cells as small as new worker-cells, even though they may have formerly been larger. But I suspect there may be a mistake here, even with so great an authority as Berlepsch back of the statement. Were these cells as shallow as worker-cells? As the bottoms of cells become filled with cocoons, the bees prolong the cell-walls at the mouth, making old cells as deep as new. Moreover, a close examination of old cells will show that the narrowing toward the mouth becomes less and less till the outer edge which has been freshly prolonged can have no narrowing. Suppose, however, the cells should be found just as small at the mouth—in other words, "as small as new worker-cells," then we have precisely the case already spoken of where the workers have made a heavy rim of wax, and in that case we know that worker-eggs are laid.

Taking all these things into consideration, does it not look more reasonable that the mechanical effect of position rather than the will of the queen decides the sex of the egg? There certainly appears to be some volition on the part of the workers, for they make desperate efforts to secure drone eggs at certain times, while at others the drone-cells are as carefully avoided; and it is possible that the queen leaves the matter entirely in their hands, but it is equally possible that she has a will in the matter also. That will, however, goes perhaps no further than to select a cell which by its size or shape decides the sex of the egg. If you say that she wills a worker egg, and makes the necessary muscular effort for its impregnation, the question may be asked, "Why does she not fill a drone comb with worker eggs at a time when drones are not wanted, and give the workers the wink to build wax rims around the mouths of the cells instead of first waiting for them to make the rims? Or, when she is so anxious (if it is she and not the workers) for drones that she will go two combs outside the brood-nest to find a little patch of drone comb in which to lay, why does she not use her will power to lay drone eggs in some of the worker-cells? If she is too intelligent to lay drone eggs where she knows they would not have room enough to grow, why does she not lay drone eggs in some of the incipient queen-cells where they surely would have elbow-room?"

C. C. MILLER.

Marengo, Ill., July 20.

Look here, friend M. I do not know that I can help you just now in this matter you have so well summed up and arranged; but I think I can push you out into still deeper water if there is where you want to be. You have not said any thing about the experiment of removing eggs from worker-cells to drone-cells, and vice versa. As this always results in having the egg produce exactly what it would if it had not been removed, it will rather help your position. But we have another suggestion from one or more writers. This is, that the worker bees manage the whole thing by performing some sort of operation on the egg, or possibly giving the infant bee something, or withholding something just as soon as it has broken the egg-shell. Perhaps the proper kind of medicine is put around the egg to change it just be-

fore the egg-shell breaks. In that case the worker bees have entire control of the matter of sex. You know there was quite a stir made a few years ago because some one suggested that the bees have the power of making eggs laid in the worker comb produce drones when it becomes desirable to do so. For instance, if you take a frame of worker comb containing eggs in worker-cells and nothing else, and put it in a queenless hive, more or less drones will be found emerging from worker-cells; whereas, had the frame been left in the hive where the eggs were laid, there would have been no drones at all. Some of the "big lights" sat down on us rather heavily because we insisted that such was the case. Now, doctor, if you never tried the experiment, suppose you do so. If the worker bees can make a worker egg produce drones when it seems desirable, it will have quite a bearing on the point you have started.

REVIEW OF DR. MILLER'S ARTICLE, PAGE 445.

DEEP SPACE UNDER FRAMES.

I HAVE only failure to record with any thing over $\frac{1}{2}$ inch under frames. Comb is either built down to the bottom-board, or knobs and pinnacles of comb are put on the bottom-board to bridge the distance. I do not think the doctor will find any help from wide or thick bottom-bars. I have in use bottom-bars 1 inch, $\frac{3}{4}$, and $\frac{1}{2}$ wide, and $\frac{1}{4}$, $\frac{3}{8}$, and $\frac{1}{2}$ inch thick, and I much prefer a bottom-bar $\frac{1}{4}$ or $\frac{3}{8}$ wide by $\frac{1}{4}$ inch thick, to any other, as it is so much easier to put such a frame into a hive and take it out without crowding or killing bees; and I am not sure, but I think comb is built down to it closer than one wider. All we need of a bottom-bar any way is to keep the two end-bars in place, and serve as a check to the bees in building comb downward.

COVERS.

I have used flat covers for years, but I can not say I am pleased with them, for just the reasons mentioned by the doctor;

i. e., the twisting and warping so as to let cold wind blow in when we want every thing snug and close. If it were not for the weight and awkwardness of the old Langstroth cap, I would adopt it at once; but it is awkward, clumsy, and expensive, and also must have a cleat all around the hive to support it, which adds to the cost and takes up so much room in the cellar during winter; also fills a wagon to no purpose if you wish to haul hives or bees. I have used a modified style of this cover, or, rather, a modified Simplicity, a few for several years, and have 70 of them now. They give so good satisfaction that I am willing to call it the best cover yet. The top should be made of two pieces, and covered with tin well painted. The rim is 2 inches deep, and rabbets $\frac{1}{4}$ inch by $\frac{3}{8}$ inch. It should not fit too close, so as to allow for the swelling and shrinking of the hive. No shade-board is needed with this cover, but the frames must be covered with a cloth or enamel cloth (I prefer the latter) to keep the bees out of the $1\frac{1}{2}$ -

HATCH'S HIVE-COVER.

inch space above the frames. With a flat cover such as the Dovetailed hive has, I have not been able to dispense with a shade-board, and really that cover is the only fault I have with the Dovetailed hive, and my home yard is provided with them now, 10 frames to the hive, however. No more 8-frame hives for me.

KEENEY'S PLAN OF WIRING.

□ Wiring frames has never been a hobby of mine;

but nevertheless when this plan was given in GLEANINGS its merits were so clear I adopted it at once, with a limited experiment on some two or three frames. I have concluded that one of the diagonal wires may be left out, and yet the foundation is held in place all right. This allows all the wiring to be done with one piece of wire, which saves all of the time of splicing and fastening, which comes so awkward to clumsy men's fingers. The inclosed diagram will show how I mean. At first I thought the other diagonal wire was the one, if any, to leave off; but experiment proved I was wrong.

ARRANGEMENT OF HIVES.

The plan of the doctor's, of setting four hives in a cluster, is all right for compactness. I tried it at first and found it was all right as far as the bees' interest was concerned; but there is no quiet alley for your wheelbarrow and tool-box to stand in; and the hive that stands just in the rear of the one you are at work with is almost sure to get stirred up and to put in a pointed protest, while the one at the side of the one you are at work with, facing the same way, I mean, if it does show irritation can be very quickly quieted by a whiff of smoke at the entrance, for you are in just the position to see them and throw in that aforesaid quieter. See, doctor? As to bees from the other row annoying, 7 feet away will be found ample room for them to get over the doctor's head, even if he has one of his three-sided stools to sit on, and is at the top notch of it.

C. A. HATCH.

Ithaca, Wis., June 20.

Thanks, friend Hatch. You have given us just the facts we have wanted to know more about. The fact that the bee-space under the frames is a failure in one or two instances is worth scores of others proving that the bees did not fill this space with burr-combs. Dr. Miller, a short time ago, you remember, reported that they were a failure with him almost the first thing in the season.—I do not know but your point about narrow bottom-bars is well taken; and it would be, perhaps, worth our while to consider it. Who else can give us some facts from experience on this point?—Now, friend H., I do not like your cover. We have used virtually such a one for a good many years in the shape of the old Simplicity. I can not see any use in having this inch or $1\frac{1}{2}$ -inch space above the frames. It necessitates the use of enamel cloth, or some sort of covering. The more we use the flat cover, the more we like it. So far, in a year and a half or two years, we have had no covers that wind, that were properly made. We paint our covers on both sides;

and we do not want any more of them, as I explained to Dr. Miller some time ago, covered with tin. If the ends are let into the grooves in good substantial cleats, there will be no warping. It is true, there may be, in time, a little winding; but if there should be, the high corners can be leveled up by putting the cover under a weight in such a way as to bring them back to position. With thick top-bars, and no enamel cloths or other covers, to my notion we shall have all that can be desired. Referring again to the winding, your cover will not be entirely proof against it, I think. Our old Simplicity covers that have been used for some seven or eight years have begun to show this undesirable feature somewhat, and I can not see how a cover cleated all around is much better than one cleated on two ends, in this respect.—I like your improvement on the Keeney method of wiring. I can not now imagine why I didn't think of it before. In making the engraving I gave instructions to make the point 6 toward the top of the frame instead of toward the bottom, as you made it in your drawing. Six is very securely braced, and will prevent the sagging of a thin top-bar. It is at this point where most of the heavy strain comes. The horizontal wire 1 and 2, when reversed so as to be parallel and immediate to the top-bar, will not hold as great a weight as the wire braced as at 3, 6, 4; 1 and 2, immediate to the bottom-bar, is not required, usually, to support any weight of honey, so I should prefer to begin at No. 1 to bring point 6 next to the top-bar, rather than to bring 6 near the bottom-bar. I understand the reason why you prefer to have the horizontal wire near the top-bar; and that is, to keep the foundation from folding over, which it is liable to do if wired as shown above. But to prevent this, cut a wide groove on the under side of the top-bar, and push the end of the foundation up into said groove. Then imbed the foundation on to the wires. We have tried frames wired as above, and they worked beautifully. Our thanks are due to you, friend H., for suggesting the use of one wire only. I believe it will be strong enough for all purposes; and it is at a considerable saving of time over the two-wire plan.—Let us hear from you oftener, friend H., by way of criticism or otherwise. Your pen smacks of experience. E. R.

ANOTHER METHOD OF GETTING BEES OUT OF BOXES.

NO USE FOR HONEY-BOARDS.

I SEE quite a good deal in GLEANINGS about getting bees out of boxes or section-cases, bee-escapes, thick top-bars, etc. I will try to tell you how I have managed for some years past to get bees out of surplus cases, not to have any robbing, and but few stings. I commence to take off honey any time when it is warm enough for the bees to fly nicely. I start the bees down with smoke, then take off the case quickly, turn it over on my left arm, and brush them with goldenrods when in bloom. The bees don't seem to get cross when brushed with goldenrod tops. I brush the bees from the

lower side of the case down in front of the hive; then set the case on a stand near the hives I take the cases off from, and pile them up as high as convenient. I have an empty case with thin muslin tacked on the top, which I keep on the pile of section cases. I keep right on taking off cases until I get off all I want at that time. If it is off from a hundred hives it would be all the same. Then if the bees are lively I can go to the first pile with brush in hand, take off the muslin case and brush the bees from the top of the honey-cases and give the muslin case a quick shake and put it on the cases and go to the next pile; and in a short time I have the bees all out without any robbing or stings. If there happen to be brace-combs, so much the better, for the bees will go for the honey and seldom uncup the honey in the sections. The same is true of the frames I have been using lately. They have thin top-bars plump $\frac{3}{4}$ inch thick. That accounts for the brace-combs on some hives. Now, I have tried a number of different ways to get bees out of sections; but the way I have described above suits me the best.

THICK TOP-BARS.

I wish to write a little about thick top-bars, so I will go back a little. I have been keeping bees nearly 24 years. I was first attacked with the bee-grip in 1866. While I was working on a farm near Davenport, Iowa, I happened to be at one of my neighbors in harvest time. At dinner they had some genuine clover honey on the table. He kept 30 or 40 hives of bees in Langstroth hives. He had Langstroth's book on bees, which I read some that noon. In the fall I was at Davenport at the county fair. There I saw the Child's patent bee-hive. I was taken up with it so much that I invested \$30 in rights, etc. I use the hive now to store bee-papers in. I should like to give you a little of my experience with that hive, if I had time. I made some hives with frames that hung on hinges; and to handle them (as there were no projections) I made my top-bars $\frac{3}{4}$ inch thick, with a groove on each side, made with a round plane. I don't remember of ever being bothered with brace-combs. My top-bars were always clean. I had a plump $\frac{1}{4}$ -inch bee-space between sections and hive. I have used thick top-bars most of the time since I have been keeping bees.

I believe the queen-excluders are a good thing, but I have no use for break joint honey-boards. Perhaps I should have both on hand now if I had not used up my surplus change in two trips to Florida and one to Cuba. For the past three or four years I have got the most honey with the least work and the least stings I have ever got. I have never failed in getting some honey to sell since I have been keeping bees. I never have fed 10 lbs. of sugar to get one lb. of honey. This is a poor section for white honey. It is a buckwheat and goldenrod section.

The honey-case I am using at present suits me best of any thing I have ever had. I can put on 28 sections with separators, or 32 without, or half the number if I wish. I used to dread to clean up sections for market, but the way I have them now it is a pleasure. This year I have sent sections to market that were nearly as clean as when they were put on the hives. I have a wide frame that holds four sections. When the sections are full they will weigh exactly 1 lb., without glass. They are held in the frames with a thin wedge or a couple of wire

nails. They want a little play, say $\frac{1}{8}$ inch or $\frac{1}{16}$, to come out easily. After I put the sections into the frames I don't take them out until I send them to market.

BEN. FRANKLIN.

Franklinton, N. Y., Feb. 1.

Friend F., your plan of getting bees out of boxes is substantially the same as I described a year ago, while on a visit to Dr. Miller, if I am correct. Thanks for your suggestion of a good use for patent bee-hives. Keep them for storing bee-papers.

ARE BEES TAXABLE PROPERTY?

SOME GOOD ARGUMENTS IN FAVOR OF TAXING THEM.

Friend Root:—I see, in reading over GLEANINGS for July 15, 1890, where Jas. R. Whipples asks the question whether all bees are taxed (or, in other words, assessed). I will say that, to the best of my knowledge, they are not, especially here in Wisconsin. I am well convinced that it is not a State law, but done by officers of the different townships. One illustration will convince any one. In the town of Boscobel, where there are quite a number of apiaries, all No. 1 swarms are assessed two dollars each that are owned on the first day of May. But in the town of Marion, just south of us, bees are not taxed at all.

Day before yesterday I had a short conversation with Mr. France, of Platteville, Wis., and this same subject of taxation came up. He told me that a part of his bees were assessed and a part not, all owing to the different townships they were located in. So you can see that it is governed by the several townships instead of the State. But if I had my own way about taxing bees, you may rest assured I would assess every one of them. If a man has \$500, or \$1000, and perhaps much more, invested in bees, tax them just the same as sheep, cattle, horses, or, in fact, any other kind of property; and in my opinion, when this is universally done there will not be as much fault-finding by parties who are not in the business; and if litigation should arise, I am sure that it would be much more difficult to declare them a public nuisance than if they were exempt from taxation; and my advice would be to insist on an assessor listing them every time. B. E. RICE.

Boscobel, Wis., July 20.

AGAINST TAXING BEES, BUT IN FAVOR OF TAXING HIVES AND FIXTURES.

On page 531, current volume, Mr. Jas. R. Whipples seeks information of you as to whether bees are assessable property in the different States. No more important question is presenting itself to our fraternity. For 25 years no assessor in our district has had the audacity to assess bees; but I am now surprised by a ticket being presented for last year's assessment, made in my absence. Custom makes law, therefore it is against the law in this State, without a special statute providing for it. I know what has been your position in the matter; but, while no one respects your judgment more than I, I feel that I shall be supported by the majority of bee keepers in this position; viz., that bees come under the head of wild animals, uncontrollable, and very greatly subject to the vicissitudes of climate and disease. An apiary may be assessed in March; in May, not a bee may have survived. Where is the

justice? I, for one, say assess hives and fixtures, but not the bees. I propose to make a test case of it in this State, and to call upon brother bee-keepers in the State to aid me. J. C. CAPEHART.

St. Albans, Vt., July 24.

Friend C., we would advise you to read the article at the head of this. If you class bees as wild animals, uncontrolled, and exempt from taxation, town councils might then with some justice declare them to be a nuisance. No, sir, friend C., let us pay taxes on our bees, and consider them as animals under control, like any ordinary stock. If any disgruntled neighbor wants them removed, you can then declare them property, like any other property, because you pay taxes on them.

FIXED DISTANCES IN ENGLAND

INDISPENSABLE, AND WHY NOT IN AMERICA?

My Dear Friend:—For by that title I assume to address you, though I have never before written to you; yet, as a fellow-apiculturist, I claim the right. I have of late had the opportunity of reading GLEANINGS (i. e., since the departure of my friend W. B. Carr for London, and my taking the house till then occupied by him), and I am not a little exercised at the discussion which appears therein about "spacing of combs." In this country the custom is, almost universally, to use metal ends to space the combs; and the convenience of them is something to be wondered at—no shifting of combs when lifting—great security when moving the hives to any distance, as, instead of an inch bearing at each end of top-bar there is a bearing of $1\frac{1}{2}$ inches. Why, then, I ask, is it that in your country you appear to ignore these very useful adjuncts to the apiary? With the metal end known as the W. B. C., it is possible, without removing the end from the frame, to get any distance from $1\frac{1}{4}$ to $1\frac{1}{2}$ inches, and this, I take it, is as much as is required by any apiarist. It seems to me, at this distance, that Dr. Miller is somehow considerably prejudiced against ends of any description; and though in his discussion pro and con, page 451, he has endeavored to argue the point out without bias, he seems to me to be unable to quite get rid of that prejudice.

Further, it seems strange that you on your side should now be going over and over again, grounds that were here settled years ago.

In conclusion I would say, let ten or more American apiarists each work, say, three hives with W. B. C. ends for a season, and then report fully what advantages and disadvantages they found from their use, and I am inclined to think that A. I. Root and others will have to stock another article. HAROLD H. LINDON.

Liverpool, Eng., July 7.

We are very glad to get your testimony, friend Lindon. We were well aware of the fact that your countrymen used, generally, fixed distances, though we have not called particular attention to it, because national peculiarities and climatic conditions might not argue for it in this country. Still, if fixed distances are necessary with you it would seem that they would be almost indispensable in America, with its many systems of out-apiaries, necessitating, as they do, more or less moving of bees. Thanks

for calling attention to the W. B. C. metal ends. We will try to illustrate them soon.

BROOD-COMBS.

OBJECTIONS TO THE WIDE SPACING OF BROOD-COMBS.

THE following article we take pleasure in copying from the *American Bee Journal* of July 19. The arguments presented for 1½-inch spacing are convincing.

I have watched with great interest for the replies to Dr. Miller's articles on page 214 and 365, relative to the proper spacing of brood-frames. If the doctor holds himself in readiness to be convinced by the reports of the box-hive men, I have no doubt he will adopt the 1½-inch spacing. The bees evidently plan for a large amount of store-room above the brood, and as a consequence the combs in box hives and hollow trees will usually be found to average 1½ inches from center to center. Thick combs above necessitate wide spaces between brood-combs below, and I have no doubt that, in a state of nature, this is the best possible arrangement for safe wintering. But when bees are wintered in the cellar or in chaff hives, I am of the opinion that this matter of close or wide spacing cuts a very insignificant figure.

I am fully satisfied that wide spacing is "nature's way," and I am just as fully satisfied that I can not obtain the best results in comb-honey production by following it.

Three years ago, when I adopted the Van Deusen metal corner for brood-frames, I adopted the 1½-inch spacing with it, for the irons were not then made any other width; but the stern logic of facts has compelled me to go to the expense and vexation of changing to a closer spacing. Now let us see why:

Since brood-comb is only about ⅓ of an inch thick, the 1½-inch spacing permits a considerable thickening of the upper part of the comb for storage purposes. If the whole upper part of every comb were equally thickened, no great harm would be done, but such is not the case. All conceivable varieties of thickness and thinness occur, the undulations of surface on each comb conforming to those adjacent combs, rendering it, in many cases, impossible to change the relative position of combs in the hive. Such combs will not fit anywhere, only where they were built, unless they are shaved off, and who wants to handle frames under such conditions?

The next difficulty with the wide spacing is a little more serious, for it affects the brood-rearing capacity of the comb. Every bee-keeper knows that worker-brood is seldom if ever reared in cells more than seven-sixteenths of an inch deep; and it is evident that, the greater the area of thickened comb, the smaller the brood area will be. Colonies that have a tendency to store honey in the brood-chamber will thicken an undue proportion of their combs, thus restricting the queen to the lower part of the central combs. It is useless to argue that the bees will cut these cells down when needed again for brood—they will not do it, as I have learned from sad experience. There are many combs in my hives, that, by improper reversing, were made thick at both top and bottom. In the center of these combs is an oval area of brood comb that comprises probably one-third of the entire area of the comb. This is the second season they have been in that condition, and I can not determine that the bees have cut down a single cell for the purpose of brood-rearing.

A third objection to the wide spacing is, that, so long as the bees are amply provided with storage comb in the brood-chamber, they are slow to enter the sections. The reasons are obvious. The limited brood area has reduced their numbers, and an ample supply of honey in the brood-chamber has removed all anxiety to provide further for the future.

At my earnest solicitation, the width of the Van Deusen metal corner was reduced to one and eleven thirty-second inches, and hereafter all my brood-combs will be spaced that distance from center to center. Whether that is just the right distance or not, I do not pretend to say; but I know from pre-

vious experience that it suits me much better than the wide spacing.
DENISON, Ia. Z. T. HAWK.

Mr. Hawk's experience re-echoes our own, except that we find that sealed worker-brood is about an inch thick. However that may be, Mr. H.'s point (that *more* brood can be reared on narrow spacing) is well taken. The fact that brood is not raised in deep cells is a pretty convincing argument for the narrow spacing.

WOODMAN, SPARE THAT TREE.

THE ENORMOUS CONSUMPTION OF BASSWOOD IN OTHER DEPARTMENTS OF TRADE BESIDES THE BEE-BUSINESS.

I READ the article on page 490, entitled "Woodman, Spare that Tree." While it is a fact that our basswood forests are being rapidly destroyed, friend Markly probably is not aware that the uses he mentioned for basswood cut but a very small figure in its destruction, if taken alone. All of this part of the State of Wisconsin has been a heavy basswood region; and but a few years ago, before the destruction of the pine forests, basswood was held as of but very little value. But as soon as pine timber became scarce, basswood began to be used for flooring, for sheeting-boards, for siding, scantling, and general building purposes. Then came its use for barrel-staves and heading, for wagon-boxes and other light upper work for buggies; for berry-boxes and crates; for excelsior; for the veneer-mill for the manufacture of material for shipping plants, etc. After every large tree had been cut for these various purposes, the small trees came in for making broom-handles. This is only a partial list of its uses. You will see that the bee-business takes but a small portion of the amount consumed. It is estimated that, within a radius of a few miles around here, the yearly consumption of basswood for the various purposes mentioned amounts to over twenty million feet annually, until now basswood-trees are few and far between. If other woods were used, whitewood and poplar would take the place of basswood, and make just as good sections.

Another thing to be considered is, that until recently cattle have been allowed to run at large, and these are very destructive to young basswoods; in fact, it is almost impossible to find young basswoods growing where cattle run. Now that cattle are restrained wherever we go, we find young basswoods growing thickly, and in a few years (unless wantonly destroyed) they will take the place of the old crop of trees already cut, and gone. A few days ago I went into the woods for the purpose of getting at the facts, and I counted about 40 trees from 2 to 4 feet high on less than an eighth of an acre, so that, while basswood honey will be scarce for the present, the young trees will take the place of the old ones in the near future; then after all it may not be looked on as a thing of the past, for basswood-trees grow rapidly, and bloom quite young, possibly in six or eight years from planting.

Clintonville, Wis., July 13.

DANIEL NOBLE.

Friend N., I am glad you have taken up this matter of keeping cattle away from young basswood-trees. Bee-keepers who own basswood timber should by all means keep their cattle out of the woodland. The

value of the food for pasture is but a small item compared with those trees. They grow so rapidly that it is going to be one of the most promising trees to raise for timber. Many of ours planted, 18 years ago, would now make a nice lot of sections, and cutting them off would harm the root scarcely at all, for young shoots start out with astonishing rapidity, and these young shoots produce both blossoms and timber in a very few years.

SPRAYING BLOSSOMS, ETC.

ANOTHER CAUTION IN REGARD TO THE USE OF ARSENITES.

GEO. E. HOVEY, Holland, Lucas Co., Ohio, has a cranberry marsh. The blossoms are still attracting the bees, but the cranberry fruit-moth is already engaged in laying her eggs. He wishes to know if he may spray his vines with the arsenites while the bees are still at work. I should advise never to spray any blossoms on which bees work. It is never safe. The fact that both brood and mature bees are poisoned by such a course makes it seem dangerous to do this. Who knows but there may be enough poison to make the honey poisonous to man? I should not wish to purchase such honey. In most cases it will be time enough to apply the poisons after the blossoms cease to attract the bees. I would advise Mr. Hovey to try the kerosene emulsion. Very likely that would be as effective as the arsenites, and that would be safe. If that does not kill the larvæ I would suggest the use of buchach. These would very likely effect a remedy for the pests, and they certainly would do no harm.

THE CALIFORNIA BEE-KILLER.

Some years ago the late Mr. Enos sent me a curious animal of the scorpion group, which he stated was a serious enemy of the bees. Except it is so rare it would be a terrible pest. Now, Mr. R. A. Hadly, of Fillmore, Ventura Co., sends me another of the same species. He says he had kept it for some days, and fed it on bees. It ate nine in one day, and some of these were drones. He says, "I put several bees into the cage with it, but I suppose they will all be disposed of before it reaches you."

Mr. H. was quite correct. The bees were all devoured, and the datamæ was dead. Indeed, it looked lank and shriveled, and as though it really died of starvation, which I dare say was the case. I have described this curious animal, with illustrations, on p. 431, last edition of my Bee-keeper's Guide. The excellent cut—Fig. 221—gives a very correct idea of this strange specimen. I named it the California bee-killer. It is a datamæ, possibly *Datames Californicus*. It seems to have four jaws. Each jaw is divided horizontally, and these peculiar pincer-like jaws—see figure in bee-book—are very formidable-looking organs.

This unique specimen belongs to the spider subclass, as is seen by its eight legs, simple eyes, and the absence of antennæ. Its long-jointed abdomen and palpi, which look like a fifth pair of legs, place it in the scorpion order, or pedipalpi, so named because the palpi resemble true legs. Thus the species and its group are related to the scorpions, whip scorpions, of which we had so much last year, and the harvest-men, or grandfather graybeards. The family is *Salpugidæ*, a small and little-known

group. One, *Datamis pallipes*, is said to feed on bed-bugs, while we know that the species in question feeds on bees. The habits of the others have not been described.

A. J. COOK.

Agricultural College, Mich., July 8.

SELLING SECRETS FOR A SUM OF MONEY.

A FURTHER CONSIDERATION OF THE SUBJECT.

THE amount of correspondence, pro and con, in regard to this matter seems to call for something still further on this subject. I may say, however, that the greater part of the communications indorse the stand taken by GLEANINGS. Perhaps half a dozen letters have been received on the other side all together; and of those half-dozen, at least four are from ministers of the gospel. These are more lengthy than the others, and some of them take GLEANINGS to task quite severely. Please let me give you a little of my experience in purchasing secrets.

When I was a boy in my teens, away from home, I met an agent who had a wonderful secret for making burning-fluid. To show me that it was non-explosive he unscrewed the top of the lamp, plunged a lighted match in it, rolled the lamp on the floor while burning, and performed various other tricks, until I was so excited that I gave him my watch, all the money I had in my pocket, and would probably have given my boots too had he not said that, under the circumstances, he would let me have the secret without them. When I went to a druggist to have it put up he told me that my compound was simply ordinary camphene. Some annotto was added to make it look yellow like oil, and some alum was put in to make it non-explosive, which did nothing of the kind. The camphene would explode, exactly like any other camphene or burning-fluid, when the lamp was nearly empty, as I demonstrated to my sorrow, before an audience of people. A lamp filled with any thing can not explode. The agent who took my watch and money falsified, and humbugged me in every particular.

Some years afterward, when I was a jeweler carrying on a shop of my own, a smooth-tongued chap came into the store with a piece of common iron rod for a cane. On the end of this rod was a coating of silver, perhaps as thick as a silver dime. He informed me that he had a secret for silver-plating that would put silver on to iron or any other metal, in any desired thickness, in a few minutes, and that the silver tip on his iron rod was done by the process. I became excited as before. As I hadn't very much money I scraped up my money and valuables in the attempt to raise \$50.00 to buy the secret. Remembering my former experience, however, I made a bargain before witnesses, that, after reading over his recipe, if I did not consider it reasonable he was to let me off, or coat the other end of the iron in a like manner right before me, and show me how it was done. He was going to put the things in his pocket, but I bade him hold on. When I came to read

the secret I found that it was something known to jewelers for years, and was what is familiarly known as the "cyanuret" process. My indignation arose at once. I told him before the witnesses that he was a swindler, a liar, and a thief. May be I was not Christianlike, but I did not profess to be a Christian at that time. He told me quietly to be careful what I said, and was so gentlemanly about it that I began to fear I had made a mistake. Finally I said, "My friend, when you came here telling me you put that silver on the iron rod by that process, I think you told me a deliberate falsehood; but to settle the matter I will give you \$100 if you will coat the other end of the rod in a like manner, by the same process, and you may have 24 hours instead of 15 minutes to do it in."

He very smilingly told me it would afford him the greatest pleasure to show me my mistake and to accept my apology, and bowed himself out with such composure that I was in great trouble for fear he should succeed. He said he would go to the hotel and get his apparatus. I watched nervously for his return. In about half an hour a neighboring jeweler came to the back door with \$25.00 in his hand, saying he had got it all ready to hand to an agent for a silver-plating process, said agent representing that I had just paid him \$50.00 for a shop-right for the same thing. My neighbor said that he had almost handed the money to the agent, for the man seemed so honest and straightforward; but to be perfectly sure, he told him he wanted to go out the back door for a few minutes. I was in a fighting mood by this time, and together we started for my neighbor's shop. The man stood in the door; but when he saw us both coming at a rapid rate, he put off at such a lively speed that we gave up the pursuit. Now, for more than thirty years I have had similar experiences. Some of our readers know that I have paid out money again and again to see if there were any honest men selling secrets. Many of you remember our friend H. H. Flick who had a recipe for artificial honey. I paid him \$2.00 for it, and then found it was the same thing that has for years been printed in Dr. Chase's recipe-book. I have talked the matter over with Prof. Cook, with the presidents of our horticultural societies, and with those who have charge of our experiment stations; and their universal verdict is, that *no good thing* has ever come through such a channel. The man who will take \$4.00 for something that does not cost him *as many cents* is off from the track, and out of line with the rest of humanity who are seeking to do good and to enlighten their fellow-men by every honorable means in their power. Many of you have perhaps seen the result of such work. If one man can sell something for \$4.00 that costs him only 4 cts., so can others do likewise, and a panic is created at once. Every little while we get a circular offering counterfeit money for sale. Now, although I do not expect to purchase counterfeit money, I read these circulars through very carefully. They start out something like this: "I suppose you know that it is

universally conceded now that no man can acquire a competence by regular day's work. It is too slow, and our moneyed men get their money in some other way. You have as good a right to get yours by a shorter cut as the rest of them. The goods we sell you are absolutely safe. In fact, they are so like the genuine that nobody can tell the difference. We furnish them for 4 cts., and you get a dollar." Now, whether it be patent-rights, selling secrets, or any other inducement that persuades you that honest, hard work, is too slow and laborious, the effect is mischievous. It is encouraging that spirit that fills our penitentiaries. And where one man is privileged to make money in this way, it is hard work to persuade people that they have not "as good a right," as the counterfeit-money circulars put it.

Imitators of Dr. Hall are already sending out their circulars. The effect on almost any community is like that of starting a whole apiary of bees to robbing during a dry time. Most of you have seen traveling men who sell dollar bills for 10 or 25 cts. apiece. The idea is so exciting that the gambling spirit is stirred up at once. Church-members, and even deacons, are oftentimes first to get crazy. Almost every community can furnish some instances of such occurrences.

Now, then, suppose we have made a discovery, or have revived something that has been dropped, that is of great value to humanity, and saves life. How shall we communicate it to our fellow-men? Why, by books and journals, as a matter of course; and these books and journals should be sold at a fair and moderate price. Our industrial publications are constantly giving information, to the fullest possible details, in almost every line of work; and good-sized books are now published on almost every subject imaginable. As soon as the need of such a book is felt, somebody is found ready to bring it forth. Riding on the cars a few days ago I glanced over my neighbor's shoulder, who sat near me, and I found he was reading a very prettily bound and illustrated book on lighting buildings by electric lights. The matter interested me because a lot of new words had just been coined, of which I should never have known the meaning had it not been for overhearing the talk of the men who recently put up electric lights in our own building. Now, rest assured, dear friends, that just as soon as any thing comes up that is really valuable, a good, fair-sized book, at a fair customary price, will soon appear, making it known to community at large. Before the book comes out, as a general thing the fullest particulars will be given through the proper periodicals. As an illustration, I will mention the silo business. Why didn't somebody charge \$4.00 for this? and would they have done more good by communicating something of so much value, by charging so much for it that whoever purchased would be sure not to let it drop because it had taken hard-earned dollars? If the good friends who criticise so severely will just suspend judgment a little while, they will, I am sure, in a little time have abundant reason to con-

clude that your humble servant has not made such a very big mistake after all.

What I have said has, of course, no reference to a manufacturer selling out his processes with his business and good will, to a purchaser, as is right and proper. But selling secrets broadcast, and advertising them broadcast, with or without a promise to tell, is an entirely different thing.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 165—Suppose that, at the beginning of the honey harvest, I remove the queen of a colony before the bees get the swarming fever, and give them a young queen that has just commenced to lay, how long after giving the young queen can I feel secure against that colony swarming?

We do not know. We never try such means.

Illinois. N. W.

DADANT & SON.

From my experience I would say it retards them almost none.

California. S. W.

R. WILKIN.

I do not believe any one can answer this. It varies greatly with queen, bees, and season.

Michigan. C.

A. J. COOK.

There is no safety with a young or old queen. A swarm may issue at any time, other things being favorable.

Ohio. S. W.

C. F. MUTH.

In a season when the swarming fever runs high it does not check them long; in other words, it doesn't pay to make the change.

New York. C.

P. H. ELWOOD.

It depends upon the weather and honey-flow. If the above conditions are favorable, they will be ready to swarm in ten days.

New York. E.

RAMBLER.

Just so long as the bees do not swarm. With me, with the Italian bee the above has little or no influence toward preventing the swarming fever.

New York. C.

G. M. DOOLITTLE.

I have not tried the plan enough to say definitely. It would depend on the size of the colony, size of hive, character of the honey-flow, and several other things.

Illinois. N. C.

J. A. GREEN.

I don't believe that taking away one queen and then giving them another laying queen will prevent swarming. I have had several swarms come off with young queens just after they commenced to lay. In some cases not over a dozen eggs were laid.

Wisconsin. S. W.

E. FRANCE.

Giving a young queen as described will greatly lessen the chances of swarming for the season, but it is not a positive cure, for at certain times the swarming impulse is so strongly developed that nothing but the removal of the queen will control it.

Wisconsin. S. W.

S. I. FREEBORN.

It would be a very practical way of lessening the swarming, but it can not be considered an entire preventive. Bees sometimes astonish us by the way they have of doing things; and especially is this the case in regard to swarming.

Ohio. N. W.

H. R. BOARDMAN.

I can only guess at it. Perhaps in most cases they would not swarm that year, and at the earliest I should not expect them to swarm within four weeks. If the bees already had the swarming fever they might swarm within a day or two.

Illinois. N.

C. C. MILLER.

If your colony has been building up rapidly, and has a huge lot of brood, many young bees, and comparatively few old ones, your remedy wouldn't work, I think. At least in my apiary I should expect them to swarm very much the same as if no change had been made. The swarming difficulty is a much tougher problem than some of the brethren estimate it.

Ohio. N. W.

E. E. HASTY.

I have never tested it—that is, while I have frequently given young queens to colonies in the early honey-flow, I have never noted or made a record of any difference in the swarming time, from that of other colonies that were not touched; hence I conclude that the strength of the colony, honey-flow, climatic conditions, etc., have more to do with the time of swarming than any change of queen.

Illinois. N. W. C.

MRS. L. HARRISON.

That depends upon circumstances—that is, on the condition of the colony and the season. I have known it to prevent swarming entirely with some colonies, and with others they would swarm in from six days to two weeks after introducing the young queen. It is safer to leave them queenless 12 or 15 days, then give them a virgin queen, and you are pretty safe against swarming.

Vermont. N. W.

A. E. MANUM.

If the bees are shaded, and have plenty of room, usually the colony thus treated will not swarm at all that season, but sometimes they will; and it is the "sometimes" and the labor, trouble, and expense of the method, which are the reasons it is not in vogue to-day, notwithstanding it is over a dozen years old. I remember one leading bee-keeper who experimented on this line, carefully, over fifteen years ago, and he gave it up, and so have all who have followed him.

Michigan. C.

JAMES HEDDON.

Well, I am a little surprised to see so few favoring a young queen to discourage swarming. Friend Freeborn seems to be almost the only one to give us any kind of encouragement; and I should rather gather from the answers, that the condition of the colony has more to do with it than the age of the queen. By the way, has not this question some bearing on the matter of preventing the building of drone comb by giving the new swarm to the young queen? You will remember that friend Hutchinson, in his book, thinks young queens are quite an advantage where bees do not have foundation in the brood-nest in hiving a new colony.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

BEES STEALING EGGS FROM ANOTHER HIVE.

Friend Root:—On page 497, July 1, you say to Mr. McGaughey that bees will sometimes transfer eggs from one comb to another. Now I want to ask you and others whether bees were ever known to transfer eggs from one hive to another. Last season I purchased of Mr. A. L. Swinson, of Goldsboro, N. C., an albino Italian queen and two pounds of bees, and put them on some frames of comb. This was the first of June; and along late in July I had an after-swarm of blacks. Not knowing from which hive they came I put them into a hive and set it near the hive of albinos. In the fall I put on them a case of unfinished sections and packed them in planer shavings, the same as I do all my bees. They came out very weak this spring, and I paid but very little attention to them till some four weeks ago. I noticed some bright yellow bees going in and out of the hive. At first I thought they were robbers, but I soon saw that they belonged there. Now, there is no difference between them and the bees I got of Mr. Swinson, and the drones are fully as red as are the albinos. I examined them a few days since, and found four frames almost full of brood, and as nice and bright a queen as I ever saw. Did they lose their queen, and borrow some eggs of their neighbors? P. L. NORTON.

Lanesboro, Pa., July 16.

Friend N., we have had several reports seeming to indicate that worker-bees do at times steal eggs from a neighboring hive, with which to raise a queen. Notwithstanding, while there are other ways of explaining most of the cases reported, I am inclined to think it somewhat doubtful. In the above case your hive must have become queenless by some vicissitude. Now, during swarming time the queen may have got away from your albino hive, and got into this one. They might raise another without your knowing it.

RAISING BROOD IN A FRAME LYING HORIZONTAL- LY; THE SHALLOW SHIRLEY HIVE.

I have just finished a curious experiment, such as I never saw in print, or ever heard of. Perhaps you would like to publish it. I should like to learn whether any one else ever did the like. I put up two colonies of bees, one on top of the other, last fall, and lately (in the middle of June) I took them apart, set them near together to equalize, and now they are both working in sections. They were in the new Shirley hive. It has closed-end frames, and is only $5\frac{1}{2}$ inches deep, and has single-story case (or hive) made on purpose to tier up for winter. I put a queen-excluder on top of the lower hive, then laid a heavy Langstroth frame (of honey) flat on top in a frame that made a rim to fit top of lower set of frames, and then set the upper set of frames, bees and honey, queen and all, on top of said rim. Each bee could help itself to the flat comb of honey, as they were both rather light in the fall. They came through in tiptop order, one of the best in the whole yard, out of 130 put up last fall. Another hive, put up in the same way, with an L. comb of honey between the two stories, came out well, and had the comb that was lying flat, filled with brood, top and bottom side as well—"head

and tails." They also stored new honey in it, top and bottom sides as well, rather ignoring the theory of cells sloping upward to better hold honey from running out.

J. O. SHEARMAN.

New Richmond, Mich., June 21, 1893.

MORE BASSWOOD USED IN FURNITURE THAN IN SECTIONS.

I see a great deal in the bee-papers about using so much basswood for sections, but nothing about other places where it is used. I believe there is a great deal more used in the furniture factories, as I work in one. I believe we use as much if not more than you do, and a small factory at that. I believe friend Boardman says he will not buy any sections of basswood. If he examines his furniture I think he will find basswood in it; at least, we put it in every suit we make, and some are almost all basswood.

WHITE-HONEY CROP SMALL.

The white-honey crop will be small in this section, or, at least, for me. I had thirty colonies in the spring, and took the brood from ten and made twenty good and strong. It commenced raining, and we had bad weather from fruit-bloom till after clover was half over, so when they should have been swarming they were killing off their drones. I had only six swarms, and other years I had more than I wanted.

F. S. BERRY.

Montoursville, Pa., July 12.

WHY FLORIDA IS SOMETIMES LATE.

Last spring I gave the reasons, at least apparent to me, for which orange-tree blossoms gave honey; the same cause is yet more striking this year, and my bees have been rearing brood on orange-blossom honey for the past three or four weeks, with good prospect for another month.

But what a contrast with last year! by the 25th of March all the bees had swarmed; whereas so far there has been, in this section at least, not one swarm, and no prospect of any before two or three weeks. What makes such a difference of two full months? A continual drouth of six months that has kept back the trees from their ordinary habits of blooming in February and March. It is no wonder that we can not supply queens as early as some parties would like to.

THE RED ANTS OF FLORIDA AS DESTRUCTIVE EN- EMIES TO BEES.

In reading in your ABC about ants, I had to smile. Our red ants here are Jumbos compared to yours, and boiling water does not seem to affect them. I have seen a whole swarm of bees decamp from their hive in the middle of the night, and crawl, beating their wings, to neighboring hives. They had been overpowered and were slaughtered unmercifully by their red foes. And the remedy? Well, I have been experimenting on several, but I won't tell just yet which is the best.

Winter Park, Fla., May 19. J. B. LAMONTAGUE.

THE SUPERSURE OF QUEENS; TWO QUEENS IN A HIVE.

In the superseding of queens I think it rarely ever happens that the old queen is killed by her daughter; but when the old lady commences to fail, the workers may not start a queen-cell at once, and she may drop off very suddenly, leaving them without any queen at all, and she may linger on and lay a good many eggs, though very scattering, after the young queen commences to lay. Some four or five years ago I traded for a lot of

black bees. When I Italianized them I took six laying queens out of three hives, and this spring I took notice of one of my best queens failing before a cell was started. I saw the young queen before she commenced to lay; and the other day, when I looked to see whether she was all right, she and her mother were laying on one frame, and on the same side, and at times would walk past each other not more than an inch or so apart.

Fairview, Md., July 7.

C. M. HICKS.

ANOTHER FERTILE QUEEN THAT CAME OUT OF THE HIVE ALONE.

Did you ever know of a queen to come on the outside of the hive, that is an old one? She is two years old. Can you give any cause? The bees are working all right in the sections.

Swartz, Pa., July 14.

A. A. SIMPSON.

Yes, friend S., we have known old queens to come out of the hive. It is, however, not a very common occurrence. I once saw a queen a year old or more come out on the alighting-board, and then go back. At another time a queen was found on top of the honey-board when the cover was removed from the hive. Others have reported seeing them come out and take wing; but it is probably quite a rare thing.

WHY DID THE BEES KILL OFF THE DRONES IN JUNE, WITH PLENTY OF HONEY IN THE HIVES?

I see in GLEANINGS where other people have their drones killed off in June. They were killing off the drones with me too, and, worst of all, with me they killed five of my best queens, and they had lots of honey at the time. Can you give me the cause? The bees were drawing them out alive, and I would take and smoke the bees and put them back, but all in vain. They would take them out again, and she had the comb well filled with brood at the time.

D. B. McMILLAN.

Mikado, Mich., July 7.

I too have known bees to kill not only the drones, but their queens, during a great dearth of honey; but I never knew them to do this when honey was coming in, even in a small quantity.

OUR FRIEND BOOMHOWER'S MISFORTUNE.

We have met with quite a misfortune, and I thought I would write and let you know of it. On the 17th of this month my papa was in a neighbor's barn getting hay, and he fell from the mow, about 22 feet, fracturing his right wrist very badly, and he had a large gash cut over his eye, and his face is bruised very badly. We are in the midst of our bee-work, and he is disabled so that he can't do a thing. But it was a very lucky fall, as he might have killed himself. He struck on the bare barn floor. Our bees are doing very well so far. We don't remember when they have been in better shape for working. But we have no one to help us with them now, and don't know what we shall do. I hope the bees at the home apiary are doing well.

EDNA A. BOOMHOWER.

Gallupville, N. Y., July 21, 1890.

USE OF TERMS; THE EDITOR SUSTAINED.

I should like to say in regard to the poplar question in GLEANINGS for July 15, that I think you are nearer right than Mr. Touchton in your use of the name. Webster defines poplar as "a tree of the genus *Populus*, of several species; as, the black

poplar, aspen-tree, etc." The tulip is an American tree, and the name poplar can have been applied to it only since the settlement of America, while in the Latin form, *populus*, the name has been applied to trees of the aspen genus (including quaking aspen, cottonwood, balm of Gilead, Lombardy poplar, etc.), for over two thousand years. Of course, popular names are decided by usage; but I think that more people will understand if you call the aspen and trees of that genus "poplar" than will understand if you call tulip-tree "poplar."

Oxford, Ct., July 26.

E. B. HARGER.

ENCOURAGING FROM TEXAS, FOR HORSEMINT.

I left Sarnia, Ont., Canada, in December, 1889, for Cameron, Texas, to take Mr. E. Y. Terral's bee-yard No. 2 on shares. I found, when I came here, 45 colonies, a number of which were weak. I moved them to a new location 12 miles away. I increased them to 63, and extracted about 3100 lbs. of nice horsemint honey. Friend Root, you would be delighted to see the great fields of horsemint. It beats our fields of white clover in the north.

A GOOD REPORT FOR THE STANLEY HONEY-EXTRACTOR.

I extracted alone, in one day, with the Stanley, 48 gallons, taking out the honey, and uncapping it and putting back the empty combs alone. The next day I took alone 40 gallons. I could not have done that with a small two-frame extractor, and two helpers.

T. H. MILLS.

Cameron, Tex., July 14.

REPORTS DISCOURAGING.

MANUM'S CROP VERY SMALL.

As the honey season is over here I send you a brief report. This being the "off" year for basswood we did not expect much from that source, though we sometimes get a little; but this year none. Owing to the wet and cold June there was but little chance for the bees to work on the abundant bloom of clover, hence our crop of honey is very short. I shall not get over 6 or 8 lbs. per colony, and but very little increase—not enough to make up the loss in winter.

A. E. MANUM.

Bristol, Vt., July 21.

HONEY CROP A TOTAL FAILURE.

The honey crop for Missouri so far is almost a total failure. A drought of three weeks the latter part of June and up to the 10th of July killed white clover and other flowers, and some bees at present are in a starving condition. Colonies that were strong the first of June stored enough honey to last them until fall flowers appear. Since July 10th we have had sufficient rain to insure a good fall flow, other things being favorable. The opening of the present season was very promising. Never before in this section was there so much enthusiasm shown and interest taken in bees, though now all is quiet, bees as well as bee-keepers. The scarcity of honey in our section will hold prices firm.

JNO. NEBEL & SON.

High Hill, Mo., July 19, 1890.

POOR YIELD IN RICHLAND CO., WIS.

One year ago to-day you came to visit me, and oh how much different this year from last! I had over 3000 lbs. of honey in the house, and honey-boxes were full. This year I have not 100 lbs. in the

house, and but very little in the boxes. Clover was a total failure; basswood less than one week, and we do not know yet what the rest of the summer will bring. Friend Freeborn and wife and daughter made us a short visit last Saturday, and he thinks if we do not have to feed for winter we should be thankful. Of honey, 87½ lbs. is the least I ever got per colony; but this year it looks dreary for us at the Riverside—no honey, and our garden was almost destroyed three times by big storms. Our bees did not increase more than 10 or 12 in 100. I am superintendent of our Sunday-school, and Helena is secretary. We left the bees to take care of themselves Sunday forenoon, and perhaps lost one or two, yet I thank God it is as well with us as it is.

Orion, Wis., July 17, 1890.

F. L. SNYDER.

NO HONEY AND NO SWARMS.

Having kept bees for threescore and ten years (but now out) I am beset by every bee-keeper I meet asking the reason why bees do not swarm, and also why they do not even occupy the sections, being filled with foundation. You probably will judge what my decision is when I say that there has been but little white clover to be seen this year, where once it was abundant, and the basswood has been in bloom for four days, and no more signs of swarming than the first of May, some having already killed off the drones. The winter here was mild, and the spring usually favorable. There are bee-keepers here that keep from 40 to 100 swarms, who have not had a single swarm, and I have heard of only two this season, and of them one went back. It is true that it is dry here now, but not so till recently.

O. E. WOLCOTT.

Mount Morris, Mich., July 12, 1890.

PROSPECTS FROM THE ALFALFA FIELDS, AND SOMETHING ABOUT THE QUALITY OF THE HONEY.

The present prospects in this vicinity for a large yield of honey are rather poor. The alfalfa is pretty well dried up on account of a short water supply. The usual June and July storms have not yet afforded the relief hoped for. I send you to-day by mail a sample of extracted alfalfa honey, and I wish you to criticise it closely in GLEANINGS. We think it fine. It is said that honey is heavier here in this dry climate than in the East. We took 45 4¼x4¼x1¼ sections from one hive, some of them not fully capped, and they weighed 42 lbs. Honey has been coming in slowly for a few days past, although *Field and Farm* reports more honey up to date than ever before.

J. T. CLAPP.

Broomfield, Colo., July 7.

Friend C., the sample of alfalfa honey you send is not only the finest in appearance of any honey I ever saw in my life, but it is also equal in flavor. We may say to our readers that it is almost if not quite as clear as water, and yet during a hot July day it will scarcely run. It is as clear as crystal, and exquisite in flavor. Very likely our friend has not a ton of such honey; but if he has, I should think it would be a small fortune if he could get it before the class of people who buy gilt-edged butter and things of that sort. And, by the way, we are using alfalfa honey on our table day after day. I never ate any other honey that suited so well, and for so great a length of time. At present the outlook seems to be that alfalfa honey is destined to lead the world.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

That art on which a thousand millions of men are dependent for their sustenance, and two hundred millions of men expend their daily toil, must be the most important of all—the parent and precursor of all other arts. In every country, then, and at every period, the investigation of the principles on which the rational practice of this art is founded ought to have commanded the principal attention of the greatest minds.

JAMES F. W. JOHNSTON.

WOOD ASHES AS A FERTILIZER.

For some years I have been a good deal disappointed because wood ashes did not produce as good results on our soil as they seem to on most soils; and this season, after our heavy business in bee-hives and sections, a pile of ashes had accumulated that looked almost like a small mountain. All our ground had been treated to ashes already so liberally that I had little faith in putting on more. These ashes, of course, are not very strong, for they are made from pine and basswood; and, besides, the great bulk of them is from coal. Before putting them on the ground we sift them with a coal dealer's screen, to take out the large cinders. Well, in one of the agricultural papers I read of a man who spilled some beet seed on an ash-heap. He was making garden, and set his package of seeds down on the ashes. To his surprise, the few seeds produced magnificent beets—beautiful, smooth, and clean, compared with those that grow in the ground. To test the matter we put some ashes on some of our plant-beds until the surface was more than half ashes. Sure enough, we have onions, radishes, lettuce, and beets growing with wonderful vigor—some of them right in clean ashes, apparently. No insect meddles with them, and their rank growth, with deep-green foliage, is all that could be asked for. We have just planted several pounds of onion seeds left over, in a similar bed. These are, of course, at this season of the year, to produce sets, and not onions. Some of them are already up, and give promise of a wonderful growth. As the ashes and ground were both sifted, all we shall have to do in harvesting our sets will be to *sift them out of the dirt*.

POTATOES AS A MARKET-GARDEN CROP.

Friend Root:—Just four weeks ago I put Vick's Early Market potatoes on the wagon, and they sold at 50 cts. per peck, for ten days, the town taking about 1½ to 2 bushels every day. The Puritans were also sold for 50 cts. per peck about June 25th. Something is to pay with the potato crop in Nebraska, and if I had only planted my Puritans instead of throwing them into the manure-heap I should have quite a little fortune, as they have done grandly where the ordinary kinds have utterly failed. I could sell 50 bushels per day at \$1.00 per bushel, on the cars, if I only had them, for Lincoln and other markets. I can always get more trade by selling potatoes on the wagon, though, of course, it makes a heavier load. Now, my object in writing is to find out whether there is any way to make the new ripe potatoes grow so that I can raise a supply for winter. Either you or some of your readers may possess this exceedingly valuable information. I have some drying very near but

under a hot roof; but I do not know that I can fool the potatoes into growing. Others in the West may like to see your enthusiasm solve the problem of making new potatoes grow. M. S. BENEDICT.

Crete, Neb., July 21.

Friend B., I know of no way to make new potatoes start up and grow like old ones that have been kept back, in a cool cellar, or buried in the ground. I think the latter way will be the best to manage it. I have made new Early Ohios grow by laying them in the sun until they became green, and useless for any purpose except planting. But this consumed valuable time, and the potatoes were much slower in starting than old ones. A neighbor of mine always saves some Early Ohios until the middle or latter part of July; then he plants them in good ground, and they come up very quickly and grow very fast. His object is to get potatoes that ripen just before freezing weather, that they may keep for seed over winter without sprouting. One season he had a crop of very fine large potatoes from Early Ohios sown during the last of July. At the prices at which we have been getting for potatoes for over six weeks, they will make a splendid market-garden crop. By the middle of June we could buy nice potatoes, brought from the South, for about a dollar a bushel; but when the old potatoes gave out they suddenly ran up from \$1.50 to \$1.60, and are in that neighborhood still. Now, this has occurred season after season, or something like it. It would certainly pay exceedingly well, at the latter prices, to start potatoes in the greenhouse, in boxes. Plant them exactly as you do cabbage-plants, putting a good double handful of rich fertilizer, from the greenhouse-bed, around every potato when you plant it. It is hardly possible that it should not prove a good investment for those who have room to spare under glass. The heat of the sun is all that is needed to start potatoes as soon as we want them. I would suggest that we have, for this purpose, an extra-early potato that is slow to sprout. At present I know of nothing that fills the bill as well as the Early Ohio.

PROPAGATING STRAWBERRIES WITHOUT HAVING RECOURSE TO THE RUNNERS.

I see in your foot-note to J. Johannsen, page 534, July 15, that you note that the other kinds of strawberries besides the Oregon are flowering in the same manner and under the same treatment. Well, very rich soil has shown the same result, but with berries that rotted badly under some observations that I have made. There is a variety here known as the Gov. Jewell, that, if very early runners are let have a chance, will mature about half a crop of fruit late in the season. You further note that you do not think that it will do to divide the old plants. I tried that as an experiment for four successive seasons, with about 20 varieties, and in no case had a failure. Take the plant up very carefully, clean off all the old leaf-stalks from the root, then separate every crown carefully; pack them nicely in sphagnum (swamp moss), and keep it just wet, not soaking, and keep them in a warm sheltered place. In four to eight days the small white roots start; then box them off in rich sandy soil, and finer

plants to send out you can not find; but don't leave on too much top. H. L. JEFFREY.

Woodbury, Ct., July 20.

Thanks, friend J. Since you mention it, I do remember having started a strawberry-bed by taking the old plants. With excellent care and plenty of manure I made them throw out new roots as you say, and I got a very fair crop; but it is more labor and expense every way, and I think without as good results as the runners gave. In case of a variety, however, like the Oregon Ever-bearing, it may be advisable to increase that way.

STRAWBERRIES AND STRAWBERRY-PLANTS FOR FALL PLANTING.

In answer to many inquiries in regard to what plants to recommend, and for a report on the new varieties, including all the latest and most important before the world, I would request all the friends to send for Matthew Crawford's July Report. Address Matthew Crawford, Cuyahoga Falls, Ohio. Friend C. makes it his business to test with great fidelity and care all strawberries brought prominently before the world, and I have the utmost confidence in his skill, ability, and honesty in regard to faithful statements in the matter. The soil and locality may not give exactly the result that yours do. But he can furnish you plants adapted to any locality. My own experience coincides with his almost exactly in regard to the value of the new varieties. I would earnestly recommend, however, that you raise *your own* plants, as a general thing. Get a dozen, or even half a dozen, at this season of the year, of such varieties as you choose, then set to work and learn the trade of making plants. It is with strawberries as with bees. The safest way is to commence with a little, and learn as you go along. When you can care for half a dozen strawberry-plants properly, enlarge to 100, then to 1000, then to half an acre, and so on. But do not, I beg of you, commence with an acre first. It will surely end in loss and trouble. Friend Crawford has for sale about 25 different varieties. As I told you in our last issue, we have decided to offer for sale during the coming fall only the Jessie, Burbach, Haverland, and Gandy. The first and last have perfect blossoms; the other two must be fertilized.

To show you something what two of our varieties look like, we will give you some

pictures, taken from the strawberry-book, noticed elsewhere.

GANDY.

The cut hardly does justice to the Haverland, but the cut of the Gandy is very accurate. The large number of petioles are of a bright vivid green, contrasting beautifully with the crimson hue of the berry. Its petiole also allows air to circulate, and keeps the berries from bruising. They hang away up from the ground, just as the berry hangs in the cut, and I think we had quite a good many fully as large as the cut.

In regard to ordering perfect-blossom plants to fertilize the others, we extract from the new book as follows:

Mr. Kellogg, of Wisconsin, and others, prefer the Jessie to fertilize the Bubach; they say it makes a strong team. Perhaps so; but the Cumberland and Bubach blossom more nearly together, and, on our soil, I think now they will do the best together. The Jessie is considerably too early for the Bubach, but just exactly right for the Haverland. I should not wonder if they made us a strong team. The Downing fertilizes the Sterling well. We have three strong teams. I hardly know which is the strongest. That row of Gandy is put in where it may help to fertilize some of the late blossoms on the Bubachs and Sterlings, which are medium late in blooming.

There are three other strawberries we are going to plant considerably, but we shall probably not be able to offer them for sale this season. The first is Michel's early, which is the same thing as the Osceola. At present this seems to be the best extra-early strawberry. The next is the Louise. These berries are very large, but of queer oblong shape, pointed at both ends, more like a gimlet-handle than any thing else I can think of. A basket of them awakens surprise at the oddity. The plant is a splendid grower, fruits well, and is almost as sweet as the Jessie. Then there is the tomato-shaped plant I described in my visit to Mr. Crawford. He says, in his July Report:

SAUNDERS.—Originated and introduced by Mr. John Little, of Granton, Ontario, one of the best-pointed strawberry-growers to be found. This was the most productive berry on my place this season, and was a great attraction to visitors. An experienced grower from an adjoining county conceded that it was more productive than the Crescent. Another grower from the same county, upon see-

ing it exclaimed, "Well! well!!! well!!!! well!!!!!" The plant is faultless, and the blossom perfect. It is very showy in the basket, being large and of an exceedingly brilliant, deep-red color. The first berry on the stem is of immense size, and quite apt to be misshapen, but the bulk of the crop is of conical form, flattened, with a suture or depression on one or both sides, extending from the center to the apex. The flesh is red, juicy, and of a sprightly, agreeable flavor. This variety, in both plant and fruit, is one of decided character, and sure to make its mark.

You remember, in the spring I spoke about making garden on ground with paths so close that one never need step on the beds in cultivating and gathering the crops. Now, there is certain stuff that I feel sure it would pay to raise in just that way. First, all kinds of plants, including strawberry-plants for sale. My plan of making these beds would be to use some 6-inch fence boards, 16, 18, or 20 feet long, just as you can get them. Make an oblong box of this, something like the top box of a lumber-wagon. Fit your ground thoroughly with a team as for any crop—that is, if your space is large enough. Then set the box on, driving stakes to keep your boards from spreading, and fill it up with compost. The paths need not be more than a foot wide. In fact, where ground is very valuable the workman can stand in a 10-inch path. Shovel the dirt out of these paths, throw it in the middle, fill up with manure, sand, and muck. If you can not get all three, use what you can get. But make your ground so it is as rich as the beds in a greenhouse, and have it so composted that it can not make a bake or crust, even if you water it every day. Now, this is what you want for the strawberry-plants. If you can not afford more than a single bed, make that one bed in this way, and put single plants, say 4 feet apart, right through the middle of the bed. With the transplanting-tubes you can take up a plant having a dozen runners. Spread the runners out like the spokes of a wheel; put a little stone—or, still better, a lump of manure—on each little plant to hold it in place; then water the ground so it never gets dry,* and just see how those strawberries will run and make plants during these July days. Why, you can do a big business in selling choice plants to your neighbors; and if your ground is spaded up and enriched, say 18 inches deep in these plant-beds, oh my! what roots your strawberries will have! I have not tried fruiting very much in these plant-beds, but I have visions of having fruiting plants all around the outside edge of the bed, with great berries the size of hens' eggs hanging over the side of these 6-inch boards. I saw that in just one case this spring, and I expect something wonderful will come of it before we get through. Just now, however, the main business is to raise the plants and to get good stocky ones ready for fruit next season. You see you can be raising plants in these plant-beds whether it rains or not; and when your crops are off, and there is rain enough to work your ground nicely, you can put your plants out in the fields when you get ready.

*A big tank or reservoir, kept full by a windmill, is just the thing during this hot, dry, dusty weather.

MYSELF AND MY NEIGHBORS.

In lowliness of mind let each esteem other better than themselves.—PHIL. 2:3.

THE world says, "Look out for No. 1." The Christian religion says, "Not so." But it even goes so far as to say, in the language of our text, that we should "esteem other *better* than ourselves." We have all heard this enjoined; and during these hot summer days, when we sit near the pulpit and listen to the good pastor who exhorts us against selfishness, we assent in a sleepy sort of general way. If somebody should take us by the shoulder and shake us and ask us what we think of such a doctrine we would likely respond, "Oh, yes! that is all right; that is what we ought to do. In fact, that is what I do or try to do as well as I can." And I am afraid we let it drop right there, without any particular idea of applying it in a practical way to the business of every-day life. And yet this world is suffering and going to ruin for the want of a practical application of the religion that most of us profess. Let us see how our text fits to actual business.

It is quite customary for newspapers and periodicals to give testimonials from their advertisers. In fact, among our "Kind Words" we have put in quite a few headed something like this: "GLEANINGS as an advertising medium." I believe, however, especially of late, they have all been flattering reports. For some little time I have had a sort of uneasy feeling that it was not fair to encourage people to send us advertisements without giving the discouraging reports as well; so I think we will have one of them right here:

A. I. Root:—Find inclosed \$1.60 to balance my account. I failed to get a single answer to my advertisement. WALTER J. HUSSEY.

Mt. Pleasant, O., July 24, 1890.

Now, that is a pretty bad showing for the value of GLEANINGS as an advertising medium. May be, however, the nature of the advertisement may have had something to do with it. Let us look it up and see. It came out in the July 1 number, so it had been before the people almost a month when our friend reported. Here is the advertisement:

PHOTOGRAPHY AND BEES.

One hand camera, 4x5 pictures, and one Scovill. 5x8, with tripod, etc., \$10 each. Also a few stands of Italian bees, which have averaged 100 lbs. of honey per stand, in Root's Simplicity hives, with wired combs, \$1.00 each. Send for particulars.

W. J. HUSSEY, Mt. Pleasant, O.

I do not know much about the average price of instruments for photography, but I should think the above was reasonable. The price of Italian bees is certainly very low. They must be good Italians or they would not have given 100 lbs. of honey each. But we must confess the fact that not one person among our 10,000 readers took any notice whatever of the exceedingly low price of bees. Probably the greatest reason for this is, that few people wish to buy bees at all after the season for honey is over. It is like goods that must be kept over for another

season. Some beginner who has the bee-fever bad might possibly invest in July; but there do not seem to be very many such now among the readers of GLEANINGS.

One other obstacle in the way of purchasing bees is, that it is a very expensive matter to ship them any distance, and a good many have been discouraged from buying bees in July, because of having combs broken down, etc., therefore we have gathered two or three good morals from friend H.'s report. But how about the \$1.60 that has been paid to us that has never given our customer *any* profit whatever? Very likely friend H. is perfectly satisfied to drop the matter and call it all right; but I am not.

When my religion is bright and clear I never feel right in taking money for something that has never done any good whatever. Friend H., the \$1.60 is placed to your credit until further orders; and if any other GLEANINGS advertisers have sent us like advertisements that have brought them *not a single application* there will be no charge for said advertisement. If, however, we should tell you when the advertisement is sent in that we fear it will not pay you, and then you should say, "Let it go in and I will take the chances," I should feel all right—that is, tolerably right, if you will excuse the expression, even if it gives you no profit. What application has all this to our text? Why, this much: We should feel just as sorry for *somebody else* who invested money without getting any returns as if we had done it ourselves. Most of us know *exactly* how one feels after such an experience. Nay, further: that faithful and devoted follower of Christ Jesus, our good friend Paul, says we should esteem other *better* than ourselves. Now, I presume a lot of good friends of mine will protest at this way of doing business. They will say, "We can not live by it." Oh how glad I am that I can tell you you are making a mistake and a blunder! No man ever failed in business because he was too honest or too self-sacrificing, or had *too much* real love for the interests of his fellow-men. In fact, it is quite the contrary. Nothing in this world can advertise a business or build it up like getting the spirit of our text into your hearts. Some one may smilingly suggest that perhaps this is the very "dodge" that I am up to now; that it is another scheme to advertise A. I. Root; but I do not believe that any of you think so. Some of you may talk that way when you are provoked with me; but you know I have demonstrated in these years that are past that a business can be built up with wonderful rapidity by putting in practice just this sort of teaching. There is nothing in this world that so provokes and disgusts a customer as to see the man or firm he is dealing with showing disregard for his interests. The spirit of our text is a comparatively unexplored region. It is so rare to see a man or a business house put it in practice—that is, looking out for their *customers'* interests better than they look out for their own—that when anybody does it it creates a sensation straightway; and it makes a bigger advertisement than would a sign over the

top of your building, with letters on it ten feet long.

It is not only business houses and managers, shops and factories, that fail to avail themselves of these wonderful gospel truths, or fail to explore this great broad unexplored region, but it is common laboring people—those who work for wages. The quality embodied in our text is so rare and so valuable that he who has got hold of the key, and who has discovered the secret, shoots up in his attainments, ability, and value so as to call forth remark. Now, do not understand me to say that such qualities do not sometimes fail, for a time at least, of appreciation. The one who commences to serve Christ by loving his fellow-man better than himself will have crosses to bear. Like Moody in his first boyish attempts to serve the Lord, he may find himself put down to crackers and water for his rations, and a hard bench to sleep on at night. But the reward is sure and certain, if he shows a reasonable and constant devotion to the interests of his fellow-men and to Christ Jesus.

You may ask why Christians do not get greater wages for their services, compared with worldly people, than they do at present, take them right through. My reply is, that their Christianity does not strike deep enough, and is not put sufficiently and directly into practice. Let me now give you another practical application of this same spirit. I am afraid it may give pain to some good friends of mine; but even if it does I am sure it will prove a lasting help to them in the end.

June 12 we received an order from Mrs. D. B. Crumbaugh, Augusta, Ky., for a lot of hives, frames, etc. The goods were shipped June 24, twelve days after the order was received, which was not so very bad for an order in June. The goods, however, did not get along in due time, so she wrote us, complaining, telling how great was their need. A tracer was sent as usual, but this did no good, apparently. Another complaint was sent and a second tracer. The card calling forth the second tracer we give below:

Please send a tracer from your depot after the things. I gave the bill of lading to our agent, and he said, send to you. *I see your letter is to Breckenridge Co., instead of Bracken, which mistake you may find is the cause.* I know if I had thought it would have been so long and so much trouble to get you to fill an order for me I would not have bothered you to do so. MRS. D. B. CRUMBAUGH.

Augusta, Ky., July 3, 1890.

You will notice the italics in the above. The writer did not emphasize this portion, but our clerk who opens the mails always reads every thing and underlines all matter of special importance. This was underlined to indicate to the book-keepers to look up this matter and see whether the goods were properly addressed. I want to put in a plea in behalf of the book-keepers. They were so overcrowded at this date that even important matters were crowded over for the next day, and a great mass of communications did not receive the careful attention they perhaps would at any other season of the year; therefore the matter in italics

was overlooked entirely. As a dozen or more tracers were sent every day for goods, I presume they had got into a mechanical sort of way, without giving much thought to it, only that more goods were to be traced or hunted up. The tracers were sent in a sort of routine way, and the kind appeal underlined on the card was overlooked entirely, and the postal card distributed. Of course, an answer was made, as we always make an answer, but it was only a printed one. We have been obliged to use printed answers quite largely during this past season, simply because they were better than no answers at all, and because we could not find anybody who could answer intelligently—that is, no one who could do it until he had some acquaintance with the business, and experienced hands were already overworked. Finally there came a letter that fell into my hands. Here is the letter, with postscript:

Mr. Root:—Again I write to say nothing has been heard of the supplies. I ordered the goods marked forwarded promptly; and if marked correctly, and in that way, it seems to me that the railroad officials ought to be made responsible to a certain degree for my loss. Here have been our hives minus frames, all during the honey season. As I wrote you before, the man working with the bees said our loss in honey was from 300 to 500 lbs.; besides, if goods ever come I am bound for them all, as, not coming in time, he has no use for them another season. I do not know what Mr. Crumbaugh would order done with them if ever found—returned to you or sent on to me. I shall have to leave that with you. Our honey season is over here for this year, and he does not think he will be here again next season. The 30 days from shipment expires to-morrow, but I usually, in my own business, receive goods before sending remittance. This, to me, has been the most worrying order and business I have ever attended to in 19 years' experience. Mr. C. will, I think, be home during August, and will then write to you. MRS. D. B. CRUMBAUGH.

Augusta, Ky., July 23.

P. S.—When you find them I think you will find them directed to Breckenridge Co., to which I called your attention before, but there is no town of Augusta in that county.

After reading the postscript I penciled at the bottom of it: "How is this?" Then was unraveled the whole shameful story. The postal card with the underlined part was brought to light, and the book-keepers were obliged to admit that no attention was paid to the suggestion that the goods had not been directed right. Going back to the original order we find that our friend wrote plainly, Bracken Co. The pen hadn't marked quite plainly, however, so it might have been considered Brecken instead of Bracken. Well, the one who draws off the orders and simplifies them for the packers, making sure that the address is *exactly correct*, took it into his head that this was an abbreviation of Breckenridge, and so added "ridge" to Brecken, sending the goods to a county that had no Augusta in it at all. For several years, at the bottom of page 3 of our price list is the following in large black type: "In one case we had to pay \$131 for sup-

plying a county that our customer did not give." It is kept constantly in our price list to impress upon our friends the necessity of giving the *county* as well as town. Our clerks, all of them, have had ample experience in regard to the matter of counties. The *county* is often of more importance than any thing else. If you have the county, the goods will generally find the town. Please notice that the responsibility falls upon a great many people in this little transaction; but it comes first upon myself. As there was just time to get a few lines mailed before train time, by my direction the book-keeper told our customer of the shameful blunders that had been made, and wound up by saying we had ordered the goods returned to us; and, more than that, if she would tell us what our blundering had actually cost her we would try to pay it.

Now for a practical application of our text. Being tired and overworked, is, I know, quite an excuse for doing things in a half-hearted, mechanical way. It is, to a reasonable extent, an excuse for a want of sympathy for those whose comfort and happiness depend upon our fidelity; but notwithstanding, if we esteemed others *better than ourselves*, and had that real feeling of sympathy in our hearts, and love for every human being, even though miles away, we should be more careful than we usually are about doing them wrong or injury, even through inadvertance. If somebody puts a great heavy boot on your corns, you can accept an apology with a pretty fair grace, especially if he says he did not *mean* to do it. There is, however, a feeling in almost every one's heart, that the man who has great heavy boots, and a big heavy body to bear down on them, should look carefully where he steps; and, dear friends, it behooves a Christian not only to look very carefully where he *steps*, but to be careful what he *does*, especially if his work be of such a nature that it may work injury that can not well be repaired. The clerk who added "ridge" to the name of the county, has a postal guide right on his table, expressly to set him right when there is any doubt in regard to an address. Had he looked in this he would have found a Breckenridge Co. in Kentucky; but had he looked further he would have found that Augusta is in Bracken Co., and this would have made him safe. We have had ample experience of the danger of "tinkering" with addresses in any way. If we direct goods exactly as we are ordered to, we can easily prove ourselves exempt from blame; but if we add to, or take from, in the least respect, we are doing a dangerous business.

Now, so far my story looks a good deal as if I were complaining that but little Christian sympathy is found, as a rule, among business people. It might look, too, as if I meant to say that *A. I. Root* has lots of Christian sympathy, and that is why he is doing so big a business. Now, please do not get that idea. A good many of you know that it is not so. *A. I. Root* once in a great while takes a *freak* of showing forth a spirit somewhat akin to that of the glorious Master. But this light he has been able to

shed to you through these pages is all a *borrowed* light. All credit and honor and GLORY belong to Him who came to a sinful world because he loved sinners. I do not know but I scolded most about that postal card with that important part underlined. When I went to the book-keeper with it she admitted that it was a grievous thing to neglect and ignore such a plain suggestion as to the cause of the trouble; but she shouldered the whole blame at once. In fact, as I understood it, she took it all on herself. A few minutes more, however, another lady—a devoted Christian, who sends the tracers—came to me saying, "Mr. Root, I send all the tracers, and it surely was my fault that that card was distributed without inquiring into the matter underlined. Tell me what it costs to make this good, and I will pay it." Then I felt happy. We had reached bottom, and were beginning to stand on the rock Christ Jesus, according to the text. I feared she did not realize, however, how great was the damage, and, said I, "Why, my friend, it may cost a *hundred dollars* to make good this woman's loss." I watched her face to see what the effect would be. I could see the inward struggle, but she bore it bravely, and replied, "Never mind, I will pay it, or my share of it, whatever is right." This, my friends, is what I call shouldering the cross in business matters. As she is a comparatively new hand, her wages are not very large; and one hundred dollars, as a consequence of passing a postal card along before it was fully answered, would prove a pretty heavy cross. The book-keeper, who has had many years of experience, and has a pretty fair salary, protested, however, and insisted that *she* was *probably* the one who passed the card along for distribution. I do not know whether it occurred to them that their old friend *A. I. Root* would never stand back and see two women lift on a burden like this without lending a strong hand. My impression is, that they did not think any thing about it; only they felt for their poor sister away off in Kentucky, who tells most plaintively in her letter of her troubles that came about through our carelessness.

The leader of our young people's meeting not many Sundays ago made the remark that speaking well of people is contagious. I spoke right out ("in meeting") and remarked, "So is fault-finding," and the whole meeting smiled. Now, my friends, this spirit of Christian *sympathy* is contagious. Why, it catches and goes like wild-fire; and if that sister away down in Kentucky does not get a little of the contagion too, and come forward and clasp hands with her sisters here, even though they have done her a damage, I shall be much mistaken. After she has seen this statement of the matter she will show a Christian spirit in making out her bill of damages, whether she be a professing Christian or not.*

* Since the above was written, the clerk who added the "ridge" to the name of the county has sent me a little note, written on his type-writer, expressing great sorrow for his error, and proposing to work for less wages until he has made up for that and some other mistakes. So you see there are

Now, my friends, a word in regard to *bearing* these crosses, or letting them slip on to the shoulders of *somebody else*. It certainly builds up business, and it builds up daily wages and salaries; but, best of all, it helps us to grow and improve in accuracy, in skill, and fidelity. A man who goes to work for me and proposes to stand the consequences of his blunders—that is, where they are *clearly* and *unmistakably* his own, makes progress “straightway,” as our good friend Mark puts it; but the one who says he “can not afford it,” or who evades the subject as quick as he can, has trouble and misfortune all his days; and, worse still, he does not seem to get over his misfortune of being inaccurate. Perhaps it is true, there are those who are unfortunately unfitted for any position where mistakes are dangerous. I have sometimes had pleasant talks with people who seemed by *nature* unfitted for exceeding accuracy. It depends a good deal, of course, on the faculty of close application to the matter in hand. I feel sure of this, however, that a spirit devoted to the great God above, who gave us our talents and abilities, will help very, very much in all these matters, and then imposing a punishment upon ourselves as a consequence will generally bring us to a “realizing sense” of our sinfulness. Besides my yearly subscription to our church, I always make it a point to put a dime into the contribution-box as it passes. Well, I have been greatly annoyed by forgetting to provide myself with dimes. I finally told Mrs. Root that I was going to cure myself by imposing a fine of half a dollar or a dollar for my forgetfulness. Soon after, I put a dollar into the contribution-box for some purpose where money was wanted for current expenses. The usher, however, brought it back to me and said it was a great deal more than my share, giving me some change. I told him it was all right—that it was my way of bringing A. I. Root to time. Well, it did the business. I attend a great many religious meetings, as a matter of course; and of late years I very seldom find myself out of the dimes that I propose to give whenever a collection is taken up. When it costs us money to forget, we get *over* forgetting.

Business has slackened up now, so that our rooms are almost deserted. A great many of the hands have gone away to labor in other places, and a great many others are out at work on the new building. My greenhouse and garden is a sad wreck; but in its place, massive stone walls are slowly rising. Now in regard to the friends who are helping to move the stone, brick, and mortar. A great many of them are unaccustomed to such work. *Some* of them have had experience. But I tell you, my friends, that even experience counts but little in comparison with a hearty good will and *interest* in what is going on. We have had men there at work who would stand and wait to be told. They would not pick up a crowbar—in fact, they would not be looking

at the work until the boss told them just what to do. Sometimes he would have to take hold of a man, and point to the crowbar, and then point to the stone. *Others* would be full of interest and sympathy. If they did not know about the tools and stone, they would ask questions. If a block of wood were wanted for a bait, before the mason could call for it they would have it right in place, and in a few hours they would get the run so that, without previous experience, they would “catch on” and go ahead without any telling at all, almost. What are these men worth who ask questions, use their eyes, and all the ability they have, to see what is going to be done, and to be on hand with the right thing at the right moment? Why, one such man is worth two or three of the former. Now, it is all in a line with having sympathy with all that is going on—having an anxiety and love, not only for your employer, but for your fellow-workers, and for the great business and machinery of human life at large. We have several German helpers among us, and some of these can not talk English very well. But I tell you, my friends, their kindly sympathy, their bright, energetic willingness, good nature, and their hearty co-operation, is worth ever so much more than ability in using right language without these qualities I have been speaking of. Physical strength is a good thing; but even that is hardly to be compared with a right spirit within. *Selfishness* and *greed* are the great obstacles. O dear friends, shall we not strive *still harder* to follow the injunction of this beautiful little text—“Let each esteem *other better* than themselves”?

EDITORIAL.

Bear ye one another's burdens, and so fulfil the law of Christ.—GAL. 6:2.

DON'T fail to read the articles elsewhere from commission men in regard to disposing of your honey crop.

SOMETHING IN REGARD TO RAISING BASSWOODS FROM THE SEED.

THE following is taken from a report found in the *Country Gentleman*, of a convention in regard to forest-trees. We hardly need add that Mr. Meehan is excellent authority:

The basswood, or linden, is one of the best street-trees that we have, as it always makes a fine, continuous growth; but an objection may be in the coloring and dropping of the leaves so early.

Mr. Manning believed that the native linden is much superior to the European in respect to the early leaf-fall, and also in not being so liable to injury from the borer. Mr. Meehan's method of raising basswoods is to plant the seed in the fall, two inches deep, and keep the soil covered summer and winter, as darkness is absolutely essential to germination; thus treated, the seed will grow almost as readily as peas.

IRRIGATION IN THE EASTERN STATES.

JUST now we are in the midst of a pretty severe drouth. In purchasing some beautiful blackberries of a neighbor just now, he remarked that he was going home to draw water in barrels to water half an acre to keep them from drying up. When I

four, counting myself, to bear the burden of damages. He will not have to work for lower wages, however, I am pretty sure; neither will anybody who goes to work righting mistakes in this way.

asked him whether it would pay, he said he had tried it for years, and it paid big. With plenty of water he will have 50 bushels that will bring a large price on account of the scarcity of fruit and berries. Without water, a few days more will make them a failure. As I write, our 1600-barrel tank is almost full, and the mill still pumping. A builder came in and asked what I would take for 16 barrels of water. I told him I had never been in the business of selling water, and that he could have it and welcome. Moral.—Don't you think a big tank, with a nice windmill, a pretty good thing to have in a dry time?

AN APOLOGY.

SOME time in April, Messrs. A. F. Stauffer & Co., of Sterling, Ill., sent us notice that they were burned out. Instead of notifying their customers of their misfortune by an editorial, as common courtesy would dictate, by some means or other their notice was set up as an advertisement, and they were charged for it. The above confession is a little humiliating, I admit, as it implies that none of the heads of our establishment really knew what had been in our advertising columns. By way of excuse, we urge the great amount of business during the past season; but I know the excuse is a poor one. Now, the whole point of this apology is, that our friends who have trusted orders with A. F. Stauffer & Co. should exercise patience and charity, and not be too severe on them. There is another moral: Although their loss was something like \$3000, by neglect their insurance had been allowed to run out. Please look after your insurance, friends, especially if you are a supply-dealer, even if you are so busy that you can not attend to any thing else.

THIS SEASON VERY DISCOURAGING; A HINT TO HONEY-PRODUCERS.

A FEW days ago we sent out a set of questions to our statistical reporters throughout the United States. As only about half of the statistical cards have been returned, we can give only a partial report; but that bee-keepers may know a little in advance what to expect, and so hold up on the price on what little honey they may have gotten, we thought best to say *now* that the cards so far received show that this year is an exceptionally poor season for honey—perhaps the worst in many years. A good many of the veterans will not get more than four or five pounds surplus per colony. With very few exceptions the report is, all along the line, "Season very poor, and prospects also poor." Certain parts of Kentucky, Virginia, Wisconsin, and Minnesota, have had an exceptionally good season. If you have secured any honey at all, don't be in haste to sell it off too cheap. The crop in California and Colorado will probably be good. We have hardly had time to get reports from these sections. We learn, also, that fruit is going to be rather scarce this year. This will help materially to stimulate the demand for what honey there is, and also to stiffen prices a little. It is no use to say bees do not pay. Farmers are complaining that they can not get a living out of the soil. Fruit-men also will probably complain about the past season. The fact is, all these rural pursuits have their setbacks. The best way is to look cheerful, be cheerful, and thank God for what we have.

Later.—Since writing the above, the prospects are brightening. Reports are coming in of large crops

of honey having been received in various localities. Clover seems to be "hanging on" longer than was expected.

A BICYCLE TRIP AMONG THE YORK STATE BEE-KEEPERS.

The writer, Ernest, expects to make a trip through York State by the aid of a bicycle and the locomotive. I shall go by rail long distances, and for short distances among the bee-keepers I shall travel on the wheel, the weather permitting. I have recently purchased a Victor high-grade Safety bicycle. I shall be equipped, also, with a Kodak camera. Many of the best bee-keepers are off from the railroad routes, and are located anywhere from eight to twenty miles apart. My object in making this trip is to get information upon a great many points connected with our industry, by visiting bee-keepers of large and varied experience, and of varied opinions as well. I propose to go to Jamestown first, to visit the W. T. Falconer Mfg. Co. If the roads permit I will then mount the wheel, pass along the shores of beautiful Lake Chautauqua, strike the railroad near the lake, and pass on to Buffalo by rail. Thence I will take the cars to Auburn, and mount the wheel and proceed to Skaneateles, and then ride along the shores of the lake of that name, and finally stop a few hours at the home of that veteran bee-keeper and writer, G. M. Doolittle. Thence I will pass on to Starville, the home of P. H. Elwood, one of the most extensive bee-keepers in the country. I hope to visit, in this vicinity, Mr. Julius Hoffman, the inventor of the Hoffman frame; then Van Deusen & Sons, of flat-bottom-foundation fame, and possibly take a short run down to some of the apiaries of Capt. Hetherington. The captain is absent for the present, I understand. Thence I expect to join my wife at Durham, on the Catskill Mountains. After a few days' outing I hope to run up to A. E. Manum's, to visit bee-keepers in that vicinity, and finally strike out for Lake George, where a camping party of some of the best bee-keepers of the land will be present. This party will consist of Rambler, F. A. Lockhart, J. H. Larrabee, and a good many other bee-keeping friends, whose names are not announced. In regard to this camping party, Rambler, in a letter received recently, writes:

Friend E. R. Root:—Bros. Larrabee and Lockhart came down on the Rambler this morning, and today the talk is nearly all on a camping party of bee-keepers on Lake George. Mr. Lockhart has secured a cottage on Plumb Bay, three miles from Caldwell, where bee-keepers will assemble from the 19th to the 22d of August, where fishing and a good time generally will be enjoyed. While we can not give a free invitation to *all* that may come, we should be pleased to see any who wish to join us, and guarantee that the expenses will not be out of keeping with a short honey season. If any bee-keepers wish to be accompanied by their wives, there will be no objections. Any further information can be obtained by addressing Mr. F. A. Lockhart, Pattens Mills, N. Y.

About 12 bee-keepers have signified their desire to form such a party, but we hope to get together at least 25. We are having such an off season that we can attend just as well as not.

RAMBLER,
Supported by Lockhart and Larrabee.

I am pleased to make mention of this trip, so that, if there are any bee-keepers along the route whom I might miss, and who would like to have a short visit, if they will let me know immediately perhaps I can make it convenient to call upon them. I ought not to go far from the Central.

P. S.—I expect to send in notes on the way.

SPECIAL NOTICES.

CHINESE ROSE WINTER RADISH.

We have given this a place before every thing else for radishes in the fall. Not only are they better in quality, but they seem to stand the hot weather better. Ounce, 5 cts.; per lb., 60 cts. Sow them any time this month or next.

CELERY-PLANTS.

We have still on hand a very fine stock of celery-plants for late planting. We have kept them growing nicely by copious watering from the windmill tank. Price 5 cts. for 10; 100, 40 cts.; 1000, \$3.00. If wanted by mail, add 5 cts. for postage for 10, or 25 cts. per 100.

OUR NEW STRAWBERRY-BOOK, WRITTEN BY T. B. TERRY.

The price of this book will be 35 cts.; by mail, 40. It will be ready to mail in three or four weeks, probably. If you get in a hurry you can have the advance sheets, which are now printed up to page 64, and when the whole book is out we will send you the work complete.

PRICES OF STRAWBERRY-PLANTS.

The price of the Jessie and Bubach will be 10 cts. for 10; 75 cts. per 100; \$6.00 per 1000. The prices of the Gandy and Haverland, 20 cts. for 10; \$1.50 per 100; per 1000, \$10.00. If wanted by mail, add 5 cts. for 10, or 25 cts. per 100 for postage. These are the only plants we have for sale at present. If you want other varieties, we would refer you to Matthew Crawford, Cuyahoga Falls, Ohio. The Jersey Queen and Sharpless are discontinued, putting the Jessie in place of the Sharpless, and the Gandy in place of the Jersey Queen.

HONEY WANTED.

We are having calls daily for price of honey, and some orders are sent in without knowing the price. As yet we have not received a pound of new comb honey with which to fill orders. There are more requests for comb than extracted. If any of our readers not too far from here have some nice comb honey in 1-lb. sections well built out to the wood on all sides, so it will stand shipping, please write us, stating the quantity and the price you expect; and if we can not make you an offer, may be we can direct you to a customer.

TURNIP SEED.

From our past experience with the Purple-top Globe, we are inclined to recommend it in place of all others for sowing in August. We have a large stock of nice seed, just harvested, the seed coming from one of our bee-keeping brethren. Price 5 cts. per oz.; 40 cts. per lb.; 5 lbs. or over, 35 cts. per lb. If wanted by mail, add 9 cts. per lb. for postage and packing. Southern Prize turnip, which stands over winter, and is specially adapted for furnishing blossoms for the bees in spring, same price as the above. This is not as good a turnip for the table as the Purple-top Globe; but it may be sown at almost any time, either in August or September.

PRICE OF UNTESTED QUEENS REDUCED.

We have quite a lot of tested queens, from a year to two years old. We desire to remove these, and put in their places young queens. All of them produce nice three-banded bees—good queens to breed from. We will sell them at the same price, until they are disposed of, as the untested. This month we make a reduction of 25 per cent over July prices. Untested queens, each, 75c; old tested, 75c; young tested, \$1.13; select tested, \$2.25. If you want an extra yellow queen, the price will be a fourth more. We can not guarantee them to be any better honey-gatherers than the average queens, and perhaps not as good. Honey queens will also be a fourth more. These queens, as also their bees, are leather colored. The progeny of our two honey queens last year gathered and stored honey while the other bees were robbing and gathering nothing. Their daughters may not produce bees any more active; but the chances are that they will be better workers than the average bees.

OUR FAIR OFFERS.

We copy the following editorial from GLEANINGS of last year, indicating what may be done in the way of education at our State and local fairs:

MAKE ALL YOU CAN OF THE FAIRS.

Our experience last fall at the Ohio Centennial at Columbus has taught us that much can be done at fairs toward educating the people in our favorite pursuit, and correcting many of the false ideas current among them. Much can be done toward correcting the public mind on the subject of manufactured (?) honey by distributing our \$1000 reward cards, and by having a comb-foundation mill, with samples of wax sheets before and after they have passed through the mill. The worst falsehoods are those which contain a grain of truth, and there is no doubt but that the comb-foundation industry furnishes a foundation and gives strength to the story of manufactured comb honey. In the minds of the great mass of the people, except those directly interested in the use of comb foundation, this product has made a vague impression, and it is not strange, knowing human nature as we do, that this foundation is exaggerated into fully completed comb, and filled with honey or a substitute. One of the best ways to correct the false notions, and shear off the great overgrowth of imagination from the facts is to show to the masses at the fairs how comb foundation is made, explaining the impossibility of accomplishing the manufacture of complete comb honey. Have a piece of natural comb and a piece of the thinnest comb foundation and a magnifying-glass, so that each may be examined. Hand to the skeptical and unbelieving one of our reward cards, offering \$1000 for proof to the contrary of your statements. In all your efforts, be patient and Christlike, remembering that these neighbors who have been misinformed have not had your opportunities for knowing the facts. If this policy is persistently carried out there can not fail to come increased confidence in bee-keepers as a class and their product, and increased consumption of honey.

INDUCEMENTS FOR FAIR EXHIBITS.

In view of the above it is to your interest as bee-keepers to make as fine an exhibit as possible. Your own product should, of course, figure largely in the exhibit. Our show-case will help display your comb honey, and you should have the extracted honey in a variety of attractive packages, mostly glass, tastily labeled.

To help fill out the exhibit and add variety, you need the various implements used in the production of honey, such as a sample hive, frames, sections, honey-extractor, knife, smoker, and what not. To encourage this part of the exhibit, we will, as in years past, allow a discount of 25 per cent from goods of our manufacture which are suitable for such exhibits. These are the conditions on which we grant this discount:

1. That you state with the order at what fair or fairs they are to be entered.
2. That you receive only samples (one of a kind). Five hundred sections, 1 lb. each grade fdn., 50 frames flat, will be counted as units.
3. That you show up the goods to good advantage, and judiciously distribute the advertising matter and samples of GLEANINGS we send along.

If you secure any premiums on the goods, they are yours. If you secure any subscribers to GLEANINGS we will allow you a rebate of 25 cts. on each name so secured. You must, however, charge the full price of \$1.00, and remit us 75 cts. of it. If you sell any A B C books we will mail them to your order at \$1.00 each, you charging \$1.25 in each case.

OFFER TO THOSE WHO DON'T BUY GOODS.

Some fairs may come off so soon that you won't have time to get the goods you would like, or you may have them already, and are going to exhibit at one or more fairs. To such we offer free one copy of cloth A B C or one year's subscription to GLEANINGS, if you will display posters, and judiciously distribute advertising matter which we will send you on request.

This outfit consists of 100 return business cards, 25 \$1000 reward cards, 10 price lists, 10 copies of GLEANINGS, 10 GLEANINGS posters, and a letter directing you how to use them. We propose to number each lot of cards sent out, and keep a record, so that we shall know from the quantity of cards of each number that are sent back somewhat how well you have done your work.

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 5 lines, and you must say you want your ad in this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. This department is intended only for bona-fide exchanges. Exchanges for cash or for price lists, or notices offering articles for sale can not be inserted under this head. For such our regular rates of 50 cts. a line will be charged, and they will be put with the regular advertisements.

WANTED.—To exchange all kinds of wall paper, for honey. 1tdfb J. S. SCOVEN, Kokomo, Ind.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

Black queens, 20c; hybrids, 30c.
J. A. BUCKLEW, Warsaw, Coshocton Co., Ohio.

I will sell a few hybrids at 20 cts.; and mismated ones at 30 cts.
C. G. FENN,
Washington, Ct.

About 10 choice hybrid queens for sale. 30c each or 4 for \$1.00.
GEO. DENMAN,
Pittsford, Hindsdale Co., Mich

I have 30 nice hybrid and 35 young black queens for sale. Send me 50 cents and get one of them.
16-17-18d A. D. ELLINGWOOD, Berlin Falls, N. H.

We are now requeening our apiary, and will have about 25 mismated Italian queens which we will sell at 25 cts. each, or 5 for \$1.00.
LEININGER BROS., Douglas, Putnam Co., Ohio.

15 black and hybrid queens for sale at 25c each, 5 for \$1.00. WM. T. REHRIG, Beltzville, Carbon Co., Pa.

A few hybrid queens at 20c each. J. A. ROE,
Union City, Randolph Co., Ind.

40 selected black and hybrid queens at 20 and 25 cts. each.
O. F. SUNDERLAND,
Box 411, St. Albans, Franklin Co., Vt.

12 or 14 mismated queens for sale for 50c each.
T. L. THOMPSON, Blairsville, Indiana Co., Pa.

Hybrid queens for sale; 15 at 40 cents each.
JOSEPH COSTELLO, Palmetto, Manatee Co., Fla.

CONVENTION NOTICES.

The Southwestern Wisconsin Bee-keepers' Affiliated Association will meet Oct. 8, 1890, in Platteville, Wis., at the residence of E. France, to commence punctually at 10 A.M., sharp. There will be a large turnout of prominent bee-keepers of the State. A question-box, free to all, in which any subject you wish discussed can be presented and answered. Let every one be on hand and bring in his report for 1890, starting at spring count, or May 1. There will be blanks sent to each member for this purpose in due time, by the secretary.

N. B.—The date of the above convention has been changed from the 1st to the 8th.

Boscobel, Wis. BENJ. E. RICE, Sec'y.

Honey Column.

CITY MARKETS.

CHICAGO.—*Honey*.—Selling well for this season of year, and receipts do not keep up with sales this week. 14@15 has been obtained for all fine white comb in 1-lb. sections. Extracted, California, 6½@7 cents; and domestic, 7 cents for prime. The quality of honey being offered is fair—not all of it as good as usual. *Beeswax*, 25@26.

Aug. 7.

R. A. BURNETT,
Chicago, Ill.

ST. LOUIS.—*Honey*.—We find ready sale for extracted and strained honey in barrels, at 6c. Comb honey steady, at 12½@13½. *Beeswax*, 26¼.

Aug. 8.

D. G. TUTT GROCER CO.,
St. Louis, Mo.

ALBANY.—*Honey*.—We have received one consignment of new honey; the quality is only fair. We have sold a part of it at 15c. From advices received, the indications are that the crop will be short in New York State.

Aug. 8.

CHAS. McMULLOCH & Co.,
339 Broadway, Albany, N. Y.

KANSAS CITY.—*Honey*.—The receipts of comb and extracted have been very light. Demand for comb good, at 14@15 for 1-lb. white; dark 1-lb. is 12@13. Very little demand for extracted yet.

Aug. 9.

CLEMONS, MASON & Co.,
Cor. Fourth and Walnut Sts., Kansas City, Mo.

DETROIT.—*Honey*.—There is a little new honey in the market, and it is held at 15 cents. Extracted, 7@8. *Beeswax*, in fair demand at 26@27.

Aug. 8.

M. H. HUNT, Bell Branch, Mich.

NEW YORK.—*Honey*.—Southern strained, 60@65c per gallon; Southern extracted, 65@70c per gal.; orange bloom, 7@7½c per lb. California, 6@7c. No new comb honey has arrived as yet.—*Beeswax*, dull and declining, 27c for a choice article.

Aug. 11.

HILDRETH BROS. & SEGELKEN,
28 & 30 West Broadway, N. Y.

WANTED.—Honey to buy. Please quote prices.

F. S. MCCLELLAND & BRO., New Brighton, Pa.

WANTED.—A quantity of light extracted honey in bulk packages; will pay 8c per lb. cash, delivered here.

C. W. DAYTON, Bradford, Iowa.

FOR SALE.—500 lbs. of good comb honey at 15 cts. per lb. cash, on board cars at Bay City, Wis., or Redwing, Minn.

FRANK DURAND,
Esdaile, Pierce Co., Wisconsin.

ITALIAN QUEENS CHEAP.

We will sell Italian queens at the following low prices: Tested, 85 cts.; one-half doz., \$4.75; untested, 65 cts. each. Satisfaction guaranteed.

A magazine for advanced agriculturists; 25 cts. per year; sample 7 cts. Also, Black Minorcas, B. Leghorns, and S. Wyandottes; eggs of either, per setting, 75 cts.; 26 at one time, \$1.00. 4-50d

C. M. GOODSPEED, Skaneateles, N. Y.

☞In responding to this advertisement mention GLEANINGS.

KIND WORDS FROM OUR CUSTOMERS.

BEEES ARRIVED SAFELY.

The bees arrived all safe in due time. I am well satisfied with them. They are doing nicely, and seem to like their new home.

Marion, Mich., July 25, 1890.

GEO. FISK.

QUEEN VERY NICE.

My bees came all right. I am well pleased with the change in my order. The queen is very nice.

Ottawa, Minn., July 14. Mrs. S. COFFIN.

BEEES IN GOOD SHAPE.

I received the queen and bees in due time. She is laying. I am pleased with her. Other goods arrived safely; all satisfactory.

Fairview, O., July 15.

E. C. MORTON.

SENDING STRAWBERRY-PLANTS IN AUGUST.

The strawberry-plants ordered just a week ago to-day are now growing nicely in my garden. They came in fine condition, and scarcely wilted a bit. Thanks for the four extra ones. I take several papers, but I like GLEANINGS best of all.

Newark, O., Aug. 12. G. H. TAYLOR.

LAYING BEFORE SHE HAD BEEN OUT OF THE CAGE 10 MINUTES.

The queen you sent me July 1 was received at 3:30 P. M. of the third, and I introduced her the same evening. I was very busy, so did not look after her till to-day, when I found her still in the cage. I pulled the cage off and watched to see how they would act. The queen started down toward the bottom of the frame around and half way up the other side, all the time poking her head into the cells, when she stopped and began depositing eggs in the cells, and that before she had been out of the cage ten minutes.

Herman, Minn., July 7, 1890.

GEO. C. JONES.

A KIND WORD FOR OUR INDUSTRIAL BOOKS, ETC.

Since your busy season is over, perhaps you would like to know how your abecedarian in this section is getting along. Every book that I have received from you has proved quite a blessing to me, for which I feel thankful to you and the great Giver of all good. We have had plenty of honey, through the instruction of your A B C book, and the carp are ready twice a day for their meal, and I intend to build another pond this fall. So much for the A B C of Carp Culture; and the A B C of Potato Culture helped me to raise 200 bushels last year. Potatoes were a failure in this section this year. Now, what I want is for you to set me right on the road of growing strawberries successfully, as I want to keep up close to the foot of the class among your scholars. Keep on with your foot-notes and sermons, and by all means with your special department for raising crops.

Tatesville, Pa., Aug. 8.

G. H. KNISLEY.

1. 24 sections, about 20 lbs.
2. $4\frac{1}{2} \times 4\frac{1}{2}$.
3. We prefer that sections shall hold a little less than a pound.
4. Our customers sell by the section.
5. None, if put up in nice shape (paper boxes).
6. Either one sells.
7. 60-lb. cans, two in a case.
8. Any time after June 1.
9. Go over it all and put it in shape.
10. We never buy, unless very low.

REMARKS.

We think this a good year to get back what was lost last year in low prices; and the shipper who gets his goods on the market early is the man to get all the advantage; for if the party does not need the money on his stock, and there were a chance for an advance in price, the seller or commission man is best calculated to know that, and can be more independent, and hold it for better prices; and if it is a large crop he can have it to sell when buyers come along.

You ask whether, if the shipper sends his crop on commission, he can get more for it than if he sells outright. Well, that depends very much on circumstances, and what he can get for it. If he can sell at the top price, no doubt that is best; but the demand for comb honey varies so much sometimes that we do not sell much before the new year; and then, again, much is sold after that time; and the

lower the price, the more of it is consumed; and as for extracted, it may sell all the time for manufacturing cakes, etc. Last year, if we had held our stock a little longer we might have got more for it; but then, two weeks later there was no demand. We are this year in much better shape to get prices, as we are known now as the depot for honey, and the only ones handling honey in a large way.

If the bee-keepers would not ship to every man who is merely in the commission business, they would get more for their goods, as most commission men do not know how to take care of honey; and if it should come to them in a leaky condition they sell at any price to get it out of the way, without going over it as we do, taking out the broken and selling it at a price for broken, and getting a regular price for the man who sends it. In that way the market is not broken in prices, and parties could not get hold of it late at such low prices, to retail it so low that other buyers will not buy it, as they can not pay regular prices and compete. So our advice would be to all who have honey, to consign it to one party in a city, and make that headquarters for honey there; we could have a wholesale and retail price for honey, which would make a fair average for the shipper. We must have the small buyer as well as the large one, to use up the odds and ends and small lots.

Our advice in shipping honey is to send 24 sections to the case, 20 to 22 pounds to the case, and pack about 100 to 150 pounds to the case or crate; in other words, pack 6 to 8 boxes in a lot, as the cases come cleaner, and are not so liable to break down in handling. Freight is the best way to send it; no matter how the extracted is sent. Cans, 2 in a case, are preferable.

E. J. WALKER.

Philadelphia, Pa., Aug. 1.

Since the receipt of the above, the follow-

ing has come to hand from Hildreth Bros. & Segelken, of New York, who reply to the questions as follows:

1. Single-tier cases, holding from 24 to 30 1-lb. sections, and 12 or 15 2-lb. sections.

2. 4 $\frac{1}{2}$ x 4 $\frac{1}{2}$.

3. Our trade demands light-weight sections in every style, whether in paper boxes, glassed or un-glassed.

4. We sell by actual weight; but the retailer generally sells by the piece.

5. Dark honey, off grades, sections mixed with buckwheat honey, find rather slow sale, and will not bring more than buckwheat, and often not as much. The same may be said of unfilled sections. A straight buckwheat in the comb finds ready sale in our market.

6. We would say, extract all dark and mixed honey, excepting buckwheat.

7. We prefer barrels and half-barrels for all kinds of extracted honey. They are the cheapest package, and we can sell them just as readily as smaller packages. Where barrels or half-barrels can not be obtained to advantage, we would recommend kegs holding about 150 lbs. or more.

8. Comb honey should be shipped to our market during September and October. Experience teaches us that the first season, the early season, is the best, regardless of short or large crop. Early in the season every one is in the market, and ready to buy at the prices established; while, later on, the stock accumulates, and buyers shop around more and hesitate in buying. In all our experience we have never seen the prices advance during November and December; on the contrary, they generally decline.

9. We sell the broken-down honey to the best advantage, generally to peddlers and cheap stores, and as quick as possible. In many cases, when the combs are not much damaged, we repack it. We make more or less claims every season against the transportation companies, but as the shipper's receipts are generally signed "Owner's risk," the company will not entertain the claim. We should like to say, always ship honey by freight, and never by express. It comes by freight in just as fine and often much better shape, and the charges are but half.

10. Most decidedly the producer receives more when consigned than when sold outright. If we buy, we take all the chance of a decline in the market, consequently we want to buy as low as possible, as we expect to make a larger profit on a purchase than on a consignment. If consigned, it is to our interest to get the highest possible prices; the higher the prices, the larger our commission.

HILDRETH BROS. & SEGELKEN.

New York, N. Y., Aug. 6.

THE SOLAR WAX-EXTRACTOR.

DR. MILLER GIVES SOME IMPROVED DIRECTIONS FOR USING IT.

I HAVE made excellent work extracting wax by tearing open one corner of an old dripping-pan, putting it in the oven of the cook-stove on a slant, and letting the open corner project out, with a vessel under to catch the dripping wax. The same pan arranged in a box with a window-sash over it makes a solar extractor, although rather clumsy,

and not always very close. But I found, as time went on, that a good deal of wax was wasted because not always promptly melted. When such things are left for some future time, that future time doesn't always come. Last spring I thought I would find out whether the Green extractor was as good as represented, so I ordered one. I have found it all my fancy painted it. If it were of no other advantage, the one simple fact that it does its work so nicely that you are tempted all the time to hunt up more bits of wax to throw in is sufficient to make it a paying investment. But why don't you send instructions with it, friend Root? True, it is so simple that any one can readily learn how to work it, but he would learn more easily if some things were told him. For instance, the matter of cleaning out the debris after the wax has all drained out. I found that the hardest thing about the whole business. I commenced on a lot of stuff scraped from the top-bars of brood-frames, largely composed of bee-glue. Each morning, before filling up afresh, I scraped out the shallow pan with perforated bottom. It had a layer of bee-glue about half an inch thick, and you can imagine what hard work it was to dig it out with a knife. Then I put it in cold water to make it brittle enough to break by pounding on it, and nearly spoiled the pan. A slip of printed directions would have been worth to me many times its cost.

For the benefit of some who may hereafter get these extractors, let me give a few suggestions. Set the extractor where it will get the sun throughout the day as much as possible. If you want it to have the least care possible, set it facing south, with the reflector standing perpendicular, and let it thus remain all day long. If you want to get more work out of it, change its position two or three times in the course of the day, placing it each time so it will face the sun an hour or two after you have placed it. By moving the cover containing the reflector up and down you will see the bright spot made on your pan of scraps by the reflected rays of the sun. Set the cover open enough so that this bright spot shall be at the middle of your scrap-pan at the west end. As the sun moves it will work to the east end.

To make the cover stand at any desired angle, take something like a piece of lath with holes bored half an inch or more apart throughout one end. Drive a nail in one end of the cover near the front edge, and another directly under it in the box, then slip your lath on these nails. Don't attempt to clean out your scrap-pan when it is cold. Wait till the sun warms it up melting hot, then take out the pan, and a thin bit of board or shingle will scrape it out easily. During the middle of the day, or later, you will find the wax in the lower pan in a liquid state, or at least part of it. Have standing by the extractor a milk-pan or other vessel with sloping sides, into which you can pour the part that is liquid. Or you may let the lower pan remain without emptying till it is nearly full enough to interfere with the scrap-pan. Then set it in the oven of the cook-stove, and pour out when melted. When the glass becomes daubed with wax, rub it off with dry newspaper when hot.

There, Bro. Root, amendments and additions are in order in a foot-note.

PREVENTION OF BURR-COMBS.

I haven't made the experiments I desired with different top-bars, partly because at two different

establishments I couldn't get my orders filled. I have, however, learned a little. Top-bars $\frac{1}{2}$ inch thick, accurately spaced $\frac{1}{8}$ apart, do not prevent burr combs. Top-bars reinforced with separator stuff making them $\frac{3}{4}$ deep are a great improvement but not perfection. To my surprise, even after I have scraped top-bars off clean, I do not find slat honey-boards work as well as in former years. That makes me more than ever anxious to learn how to get along without them.

Marengo, Ill., July 21.

C. C. MILLER.

Why, friend M., we do send out directions for using the solar wax-extractor—that is, we intend to do so; but I presume during the rush of business last season, somehow or other the sheet was left out. The same directions, or essentially the same, are given in "Wax," under "Solar Wax-extractor," in the A B C which you have. But you have added some items which we are glad to have. Yes, sir; when bee-keepers know more about the solar extractor they will use it more than they do. Ours is in use in the apiary constantly, when the sun shines, and we should hardly know how to get along without it now. Instead of having lumps of wax stuck about here and there, and more or less litter in the honey-house, we have instead several nice cakes of yellow wax. We do not bother to have it remelted in the oven. If your pan has sloping sides (and I presume it has) the cake ought to lift out after it has hardened. I am glad to get your testimony in regard to honey-boards and thick top-bars. I have not heard any thing positively against them, except that a few having never tried them won't use them because "they are too much wood."

E. R. R.

BEES AND CEREALS, AGAIN.

PROF. KOONS REVIEWS THE QUESTION; ANOTHER OF AGASSIZ'S BLUNDERS.

My object in asking Prof. Cook a question through GLEANINGS, see page 449, was to get confirmation on the point of the usefulness of bees on wheat, etc. I ran across the statements of M. Jobard, a French writer, in his "The First Hive," where he makes such positive statements concerning the utility of bees on the cereals; and they were so contrary to my previous understanding of the subject that it fairly stunned me. I jumped up, shook myself, rubbed my eyes, and gave myself a pinch just to reassure me that I had not been asleep, Rip Van Winkle like, all these years, and allowed the world to get so far ahead of me in the natural history of common things on land, while I, with others, during summer vacations and spare moments, have been poking our noses, or, rather, machinery, several miles down into the old Atlantic, to the bottom of the Gulf Stream, to learn what new and hidden treasures ocean depths contain. I think, by the way, that some time I must tell the readers of GLEANINGS something of our experiences and finds, out there, but not this time.

Immediately upon reading Monsieur Jobard's opinions concerning bees and cereals, I said, "I shall ask A. I. Root, or through him Prof. Cook, just for reassurance; yet I know that I am right, for I was reared among the Ohio wheat-fields, and

have observed nature somewhat closely all these years, and have never yet observed a bee at work upon wheat, rye, oat, or grass."

The statements of M. Jobard run like this: "There are some districts in Saxony where the farmers raise no other crops than wheat; and a wheat of such superior quality as to be always sold at a high price as seed wheat. In these districts all farmers, without exception, have bee-houses; but these bee-houses, instead of being fixed, are mounted on wheels. Some days before the wheat blossoms, each farmer hitches his team to his movable bee-house, and conducts it during the night into the middle of his wheat-field." . . . "I have a bee-house in the middle of a field, and it is always the field surrounding my bee-house which furnishes my seed-wheat."

But here, most likely, as is so often the case, the overzeal for a theory, or the want of a little research, led the writer to make these statements and others like them; and all the more pity, because some of his errors have been finding their way into some of the leading publications of New England, and my first step was to be absolutely sure of my ground, and then expose the errors.

Like this Frenchman, the great Louis Agassiz once wrote a very learned (!) essay upon "The Mode of Motion of Certain Sea-Urchins," when if he had gone to the water's edge half a mile from his study-window, by a little judicious research he could soon have proved that all his theorizing was entirely erroneous. Zeal for a theory sometimes leads very great men astray.

Some flowers produce only stamens, or the male organs, while others, sometimes on the same plant in certain species, and in other species on entirely distinct plants, produce pistils, or the female parts of the flower; and still other species produce both stamens and pistils in the same flower. Those possessing only pistils must, of course, have pollen brought from the stamens or they will not produce fruit; and, again, some of those possessing both stamens and pistils can not be fertilized by the pollen of the same flower in which it grew; or if fertilization does take place it is very imperfect, hence must have pollen brought from another flower to insure the perfect growth of the fruit; hence the need of the aid of insects or the wind to insure the productiveness of some of our plants. Ordinary red clover is a good illustration of a plant needing the aid of insects, and in this particular case the humble-bee is the insect that performs the work of cross-fertilization.

Again, there are other plants which reproduce by what Gray calls close or self fertilization; that is, the stamens of any particular flower fertilize the pistil of that flower; and in these, bees can play no important part; and conspicuous among these, as Prof. Cook well says, are wheat, oats, etc.; hence we can readily understand the blunder of our French writer.

I have no bee-men near me who have had a long experience, and my residence in the State is not sufficiently long to enable me to judge of the merits of this year as compared with the best of the white-clover harvest in this State; yet this has certainly been a very good season thus far, as white clover bloomed early, and the rains have been sufficiently frequent to keep it fresh and in the greatest profusion, and bees have gathered a large quantity of honey. Basswood is so scarce here in Eastern Con-

necticut that we can depend upon it but little as a honey-plant.

Bees wintered well in this State, and those who pretended to care for them at all had no losses. We keep but few here at the Agricultural School. We wintered 8 in chaff hives. There was not a month during the winter that they did not have at least one good flight, and they came out this spring in splendid condition.

B. F. KOONS.

Storrs, Conn., July 15.

Friend K., we are very glad to have you take this matter up and stop it as far as possible before these blunders get the run of the papers. By the way, it does seem strange that our newspapers grab for a blunder or falsehood, and give it no end of prominence, while true statements in great numbers are passed by. I have observed bees gathering pollen from the heads of timothy, several times, but never, if I remember, on any of the grains. For some time past there seems to have been a sort of gulf between scientists, or at least a certain class of scientists, and practical industrial people. We trust, however, that this state of things is passing by. Our experiment stations are doing very much indeed to bring these two classes of workers together, and to throw out theory promulgated by so-called scientists without *any* practical knowledge. What you say about the sea-urchins reminds me of the time when Agassiz and Tyndall undertook to teach about bees when neither of them had ever looked into a hive, apparently.

H. D. CUTTING

AS HONEY - EXHIBITOR AND EXPERT JUDGE AT
FAIRS AND HONEY - SHOWS.

Mr. Editor:—I am requested to give a brief account of Mr. H. D. Cutting's work in connection with apiculture in Michigan. Although I am very much occupied at present, my friendship for Mr. Cutting, my appreciation of his valuable services, my knowledge of his enthusiastic work, and my desire that earnest, faithful, telling effort may be recognized, all make me more than willing to undertake the pleasant duty, even though, in the hurry of the season, I may fail to do justice to Mr. Cutting and his valuable services.

A word regarding Mr. Cutting as a man is necessary to understand his exceptional success. He is always a gentleman, and so wins the regard and confidence of those he may wish to influence. His pleasing address adds further to his power of persuasion. Most of all, he believes in his cause, and so acts with an energy and enthusiasm that attracts, then interests, and at last persuades. Lastly, he thoroughly studies any enterprise in which he engages, and so becomes a master, a leader as well. So in his work he never says "go," but, rather, "Come on, boys."

In two capacities Mr. Cutting has shown signal ability in connection with Michigan apiculture; has wielded exceptional influence, and has achieved brilliant results. I refer to his position as secretary of the State Society, which I think he has held since 1881, and his valuable service in connection with the State Fair, where, owing mainly to his efforts, the premium list has advanced from \$5.00 to

over \$300, which, if I am not mistaken, is the largest and most generous offered in the United States. Our State Society stood high when Secretary Cutting assumed the duties of secretary. We had previously had the benefit of such wide awake, capable officers as Bingham, Heddon, Benton, etc., and so it was no easy task to keep the interest and work up to the high-tide mark, especially during the discouraging seasons that have marked about a third of Mr. Cutting's term of office. Yet Mr. Cutting has more than achieved that distinction. While I would not say that the interest and profit at some of the old first meetings, with Moon and Rood, Postman, etc., on deck, were ever surpassed—those old meetings were delightful—I will say that, for the whole period together, the past nine years have stood at the front. The programmes, general spirit of the meetings, and valuable results achieved, have been most admirable, as many can attest; and for all this, secretary H. D. Cutting should have chief praise.

H. D. CUTTING.

Nor has Mr. Cutting's record been any less bright in relation to our honey-exhibit at the State Fair. In the old time, honey was sandwiched in between butter and vinegar, with somewhere about \$5.00 offered for premiums. Mr. Cutting appealed, on behalf of the bee-keepers, to the authorities. His petition was listened to and granted, and now Michigan has a special building devoted to the apiary, and offers premiums to the amount of \$300. For nearly all of this we are indebted to Mr. Cutting. Nor did he stop there. The revised list once adopted, Mr. Cutting went to work with all his energy and zeal and secured an exhibit worthy a special building and a generous premium list. Few exhibitions compare with the honey-shows of Michigan in quality of exhibits and neatness of display. For all this Mr. Cutting should have chiefest praise, with Mr. W. Z. Hutchinson as a near second.

Not only is Mr. Cutting praiseworthy for his energy and enthusiasm, which have accomplished so much, but he is remarkable for his modesty and reserve. He never pushes himself to the front, but is always urging others to places of honor and responsibility. While he never pushes himself for position, he always gives most efficient service when called upon to act. Michigan bee-keepers can never be too grateful for the valuable work that he has wrought in our State.

A. J. Cook.

Agricultural College, Mich., July 22, 1890.

In addition to the well-written sketch above, of Mr. Cutting's career as a honey-exhibitor, and of his services in connection with bee-associations, we would add that our friend was born in Hudson, Columbia Co., N. Y., July 22d, 1842. He attended school and worked in a printing-office till Sept. 9, 1858, when he removed to Michigan. He began working for the Michigan Southern & Northern Indiana Railroad, now known as the L. S. & M. S., in the capacity of a baggage-man. In 1861 he left this position and went into the army. In the spring of 1863 he commenced work at Newburg, N. Y., building marine and stationary engines. He was married to Miss Frances Gardner, Sept. 27th, 1865. He now has a family of seven children—four boys and three girls. In 1867 he removed to Clinton, Mich., and started a machine-shop of his own, and he has been engaged in building machinery ever since.

He has been interested in bees for a good many years, and commenced the business in 1866. He has not been a prolific writer, but, as will be seen by Prof. Cook's sketch, he has rendered valuable service to bee-keepers, particularly those of Michigan. He was president of the South-eastern Bee-keepers' Association, also president of the North American Bee-keepers' Association for 1886, and is now superintendent of the Bee and Honey Department of the Detroit Exposition. He has acted as an expert judge of bees, honey, and supplies, at many of the largest exhibitions. Besides bees, Mr. Cutting is interested in poultry and small fruits. He is also a student of the microscope, and finds great pleasure in all these pastimes. He is strongly opposed to the use of intoxicants and tobacco, and so far none of his children use them. So much for a good example.

Friend Cutting paid us a visit a short time ago, and we found that he was not only enthusiastic on bees and every thing connected with the industry, but he enjoyed intensely talking about machines and machinery. He is a very fine mechanic, and has a splendid knowledge of almost every thing connected with his trade.

RAMBLE NO. 26.

IN WAYNE COUNTY.

THE R. & W. R. R. conducted us rapidly into Wayne County. This and several other counties bordering the shores of Lake Ontario for a distance of a hundred and fifty miles, are all noted for their fertility, and especially for the fruit interests centered there. Large orchards of apple, pear, and

other fruits, both large and small, are visible at all stages of the journey. Peaches are also grown to a certain extent. As a consequence, from so much fruit culture Wayne County is one of the pioneers in the evaporating industry; and taken up at first on apples, the industry now extends to all kinds of fruits and to many vegetables. Every village has one or more large evaporators; and many small ones, with a capacity of five or ten bushels per day, are seen in farmyards. We learned that peppermint is also raised to a great extent in this county. In fact, a great share that is put upon the market is produced here.

In the pleasant village of Williamson we met Mr. Ashmead, who has kept bees quite extensively, but now has only a few colonies. Mr. A. fills out his spare time with taxidermy, and also in the fruit-business. He has spent several winters in the South, especially in Florida and South Carolina, and has had much experience in different localities, and thinks that western New York, and especially Wayne County, will not give bountiful yields enough to warrant any one to make a specialty of bee-keeping. While the immense orchards may yield much honey, the weather is usually unfavorable for bees to take full advantage of the brief honey-flow, and it is only in an exceptional year that bees store any surplus from this source.

After a brief call we sought the object of our journey into Wayne County, an old-time relative, and stopped over Sunday with him. We found him interested in fruit culture, but not in bees, and also found him, with the aid of the *Free Thinker*, trying to prove that Lincoln was an infidel, and also trying to demolish Samson. As to whether Samson rent the lion in twain or not, seemed to the Rambler a small thing to argue over. We do not pretend to understand all that happened over 3000 years ago; but we do know, both Christian and infidel, that a new era dawned when the gentle Galilean came upon earth, and gave us a religion of love; and if it is a failure in any place it is not the fault of the teachings, but of the one who does not receive the truth. This stumbling over things we can not understand, and which are of no vital interest to us in this era, was neatly illustrated in a sermon heard by the Rambler. Said the preacher, "When you eat a fish you pick out the bones and lay them aside and consume the life-giving flesh. So with the Bible. When we come to a hard bone, lay it aside; there is untold richness for the mind to feed upon without. But, my hearers, how many are devoting their energies to the gnawing of the lifeless skeleton!" Our friend, though versed in the false doctrines of the *Free Thinker*, was not so well versed in the Scriptures; for while in Sunday-school in the afternoon, the teacher asked him for a passage of Scripture from Hebrews; and after fumbling through Isaiah and the Psalms, said he in the Rambler's ear, "Where in the Dickens is Hebrews?" My opinion was clear, that more study of Scripture and less of the *Free Thinker* would have resulted in a far different moral condition of his mind.

I found my friend putting much faith in sigas and other superstitions; and his theory as to the cause and cure of fever and ague was peculiar. He claimed it to be a spinal disease, because the chills run up the backbone; and a sure cure for it is to crawl downstairs head first for several days in succession.

Well, we left our friend with his infidel books and his theories, and we next met with a genuine surprise. We met, near Charlotte, an old friend who formerly peddled honey for the Rambler. His experience in bee culture on his own hook had shown him the ups and downs, like all the rest of us, and we found him immensely enjoying the downs. His family called such spells tirades. His fit was the most exasperating we ever saw. It had taken hold of him bad, both internally, externally, brain and muscle. We found him near the wood-shed, surrounded with bee-hives that had formerly been a joy, and he was just slivering them into kindling-wood. In our astonishment we cried out, "Why, friend Blake, what on earth are you doing?"

"DURN THE BEE-HIVES!"

"Durn the bee-hives," says he; and after a final finish of the one under dissection, he rested on his ax-handle, and said:

"See here, friend Rambler, you and I have always been good friends. We played in the band together. I beat the drum and you blew the horn. I know you have a tender spot for bee-hives; but, durn the hives! I'll smite 'em worse than I ever did the drum;" and he smote another hive all to flinders.

"But, see here, friend, why don't you sell your hives? They are well made, of good pine lumber. You ought to get the price of the lumber out of them."

"Yes, yes; I know all about selling hives. Let me tell you a little story. Five years ago I came to this portion of the State to work at the blacksmith trade. I started in the bee-business, and succeeded well for two years; got up this hive; it is different from any other you ever saw, and I was going to get it patented; but the seasons changed, and I have had losses ever since, and now I have only five colonies out of fifty. Nobody wants the hives. They are odd size, and even when I do find a customer he is some poor shirk who never pays for them. So, here's the remedy; it is short and sure, and there'll be no danger of my spending any more time and money on the durned hives. I tell you, this bee-business is wonderful. You get more'n ten thousand traps on your hands; and when you want to get out of the business, nobody wants to buy. Why, I'd trade these forty hives for forty good milking-stools. I could sell them to almost any farmer."

His tirade took strong hold of him again, and with a "durn the bee hives" his ax made havoc with the fixings. Our Hawkeye caught him. We are pleased with the result, for it is a reminder of some almost similar fits on the part of the

RAMBLER.

Friend R., I am very glad you have given us a touch, with an illustration, in regard to the dark side of bee culture. If anybody should ever be tempted to go into bee culture because GLEANINGS represented that it afforded better inducement for making money than any thing else, I should be very sorry. Bee culture has its capabilities, and there are, occasionally, favorable seasons or brief periods when excellent results can be made in a very short time. And it is also true that one who is full of enthusiasm, and has the good sense and judgment to succeed in almost any business, would probably make a *fair* crop during almost *any* season. At the same time, it has perhaps more disasters connected with it than almost any other industry. Of course these may, to a large extent, be averted by keen oversight and looking ahead. As with many other rural industries, the one who succeeds with bees will probably be the one who has a *real* genuine love for them.

MORE ABOUT FIXED DISTANCES.

ANOTHER DEVICE.

NOTWITHSTANDING the fact that I have not had much experience in moving bees more than in buying and selling, nor that I know that I never shall, yet I have read all the testimonials in GLEANINGS with much pleasure. On p. 451 Dr. Miller has given Ernest what he perhaps considers a pretty good "dose." I thought I would come out and help him take it. I have pondered over each new device, to see if I could find something that would help me to space frames in a hurry, especially when I'm working with a colony that takes delight in defending its home; but I have as yet found nothing that suited me. They all have the fixed distance indeed—so much so that one can't move the frames either way to get one out. Yet Ernest's remark, in his comment on Dr. M.'s article, is a *very* strong argument in favor of some kind of spacer. As Dr. Miller says, that furniture-nail seems to be the nearest practical of any thing yet mentioned in the journals; but, hold on! I had forgotten to mention the new device I have invented. Now, Ernest, earnestly listen while I try to describe it. Take strips of heavy tin and cut them into 1½-inch lengths, ¾ inch wide; round the corners of one end, and punch a little hole in it for a tack; cut the other rather in the shape of a board sled-runner. From the long corner of this end, measure ¾ inch and give it a square bend. Now for the way to use them. When you have 20 made—if your hive has nine frames that will be the number required—tack one in the upper left-hand corner of the inside of your hive, the distance from the end you want them on the frames, and even with the top. Now take the frame next to that side of the hive the spacer is on, and put one on the side of the top-bar next to you, as near the end as you think best. Treat each top-bar the same way all through on that side. Now go diagonally across the top of the hive to the near right-hand corner, and tack one on the inside of the hive as before; then on the over side of each top-bar, making one spacer at each end of each frame, but on different sides. You see, with the longer part of the tin tacked on the top-bar, one at each end on opposite sides, the short end with the

$\frac{3}{4}$ -inch slope bent out at right angles from the top-bar, that side of the bar at that end can not get closer than $\frac{3}{4}$ inch to its neighbor, and the other end on the opposite side of the same. Now, as each frame is similarly arranged, also the hive, then the frames must stay just $\frac{3}{4}$ inch apart until you wish to remove any of them, when all you have to do is to take hold of the spacer at the folded end, and raise it up, using the tack as a pivot; thus your frames can be moved almost as closely as if no attachment were present. You see, you can have frames spaced properly, and held for moving, or you can loosen the frames for manipulating, at will.

Carbondale, Kan.

J. H. MARKLEY.

Thanks; but I hardly think that our bee-keeping friends would tolerate your device. The tins would take too much time to manipulate.

EARLY EXTRACTING IN CALIFORNIA.

EXPERIMENTS WITH THE DIBBERN BEE-ESCAPE.

The following article from L. E. Mercer was overlooked, as it came with an order for goods. Though it is a little late we are glad to give place to it now.

We commenced extracting the first of May, two weeks earlier than we ever did before since I have been in California. Honey is coming in quite freely so early in the season. Our scale hive gathered 10 lbs. on the 5th day of May. On the 3d we extracted 56 $\frac{1}{2}$ lbs. from it, all new honey. We have about 5000 sections on and nearly finished. Honey is of a much finer quality than I ever saw before, either here or in the East. Several sample bottles of it are on the table before me that I would say were empty bottles if I had not seen my wife fill them with honey. I will send you one of them, and, if you want it, several tons of the same kind.

Mr. Dibbern sent me two of his bee-escapes some time ago. We have experimented considerably with them, but they will not work for extracting. They get full of bees, especially drones, that seem to be lost, and the bees will not go through them. They worked well three or four weeks ago, before the hives were so full of bees. The drones seem to cause most of the trouble, but I have just received two more escapes from Mr. Dibbern that I think will work better, as they are only single, while the first were double; and the bees, especially the drones, would get lost between the two wires, and would fill up the space so full that they could not move one way or the other to find their way out.

You know, of course, that we have three kinds of sage here,—the black, that blooms first; then the purple, that nearly all of our honey is gathered from; and then comes the white sage, that, judging from the way nearly all honey-tables in California read, produces about all the honey here, but which, in fact, produces less than either black or purple sage. The sample I send is all from black sage, which always produces the whitest honey. The honey-flow is good at present, but the crop must surely be a light one, as we have had no spring rains. Although we had an abundance of rain in the winter, yet the honey crop is largely dependent on the late spring rains.

L. E. MERCER.

San Buena Ventura, Cal., May 7.

The sample of honey from black sage is, I think, the finest we ever saw in appearance,

and certainly nothing can excel it in flavor. It is certainly true, as friend Mercer says, if the bottle were filled it would be a very difficult matter to tell whether it contained something or not, without taking it up. Notwithstanding its perfect transparency, it is so thick that it hardly runs in warm weather. It seems to me that this honey should bring an extra price, for it is "gilt edge" if there is any gilt edge in the world.

FIRST HONEY IN THE HIVE OR SECTIONS; WHICH?

THE IMPORTANCE OF HAVING THE LOWER STORY CONTRACTED, AND FILLED WITH BROOD JUST BEFORE THE HARVEST.

Mr. Editor:—My attention has been called to your reply to question four, as asked by Mr. Naftel, on page 341. You there say, "Bees will be pretty apt, especially the Italians, to fill the brood-chamber first, no matter what the honey is; after that they will go into the supers if the colony is strong enough and there is a good flow of nectar. As a general rule, there will or ought to be enough inferior honey in the brood-nest to cause the first white honey to go above." Now, I seriously object to both these views, for on them hang all there is against the use of large hives for comb honey, as recommended by our fathers, and even by some of the present day, as opposing the contraction plan as recommended by myself and others, which to-day stands out prominently. No, sir! the bees must not fill the brood-chamber first with honey, and the sections afterward, Italian or otherwise, if we are to reap the best results from our bees. At the time the honey-flow commences, the brood-chamber must be filled with brood, with not to exceed five pounds of honey in it, and *one* pound will be far better than the five. If it is not thus filled with brood, the wise apiarist will take out all the combs not thus filled, and store them away where the bees can not have access to them at this time of the year; for if they once commence to store honey in the combs below, to any considerable extent, thus early in the season, instead of going into the boxes they will begin to crowd the queen with honey to a greater or lesser extent, thus removing the boxes further and further from the brood, till at last there will be little brood in the hive, little honey in the boxes, and the colony in very poor shape for winter on account of the fewness of the bees left, owing to this same crowding-out of the queen from the brood-combs. The work of every bee-keeper should be, during the fore part of the season, to see that his combs are being rapidly filled with brood, and all that inferior honey spoken of used up and turned into brood which is to make the bees for the harvest, till the hive is literally filled with brood; when, if there is a pound of honey comes in after this, it must go into the sections or no, where. Here is the rock on which those favoring the Italians and those opposing them as comb-honey gatherers split; for, if managed as given in your editorial, the Italians will be unprofitable every time; while, if managed as I propose, they will outyield the blacks as to honey every time; while at the end of the season they will have honey enough in their brood-combs for winter when the black bees will be almost in a starving

condition. This is not mere theory, but something any one can prove to his or her satisfaction in one year by working a few colonies on each of the two plans. This season I have been working some bees five miles from home; and as the party where they are believed that the bees should not be robbed too close, I left the whole number of combs in these ten-frame Langstroth hives, to please him. The result proves just what I have said above; for after a short honey-season I have about 50 pounds of honey in the brood-chamber of the hive, with perhaps an average of 10 pounds in the sections. If these combs had been cut down to about seven, and those well filled with brood at the commencement of the harvest, the result would have been about 45 pounds in the sections, and 15 pounds below, had the bees been Italians; or if blacks or hybrids, 40 pounds in the sections and 5 below.

One of the many things about the Italian bees which please me is their desire to store honey in the brood-chamber; for if rightly managed they will give a good crop in the sections, and at the same time generally have stores enough, or nearly so, below to winter upon. Just as soon as they begin storing honey in the sections they begin storing to a limited extent in the brood-chamber; and as the honey-season draws toward a close they seem to be on the alert as to their own interest, and the queen ceases to lay as prolifically as at first, which allows of their storing the later honey in the brood-combs for winter stores, while their keeper has plenty of the most salable honey as his share of the season's work. With the Germans, Syrians, and Carniolans, the case is different; for they continue to raise brood right along at a rapid rate so long as honey comes in from the field, so that, at the end of the harvest, we have no honey to speak of in the hives, and a host of useless consumers on hand as the result of this out-of-season breeding.

I wish to go on record as saying that one of the greatest secrets of successful bee-keeping is having the brood-chamber full of brood at the commencement of the white-honey harvest. I would certainly have it thus, even if I had to take all the combs out of the hives but three, leaving the bees but three combs below till after harvest, when I would at once supersede a queen that would not keep a greater number than that filled with brood three weeks previous to the harvest. If lack of brood is caused from weak colonies in the spring, then I would unite all colonies which were thus weak, three weeks before the honey-harvest, even if I had to divide afterward, considering that I would be a gainer by so doing, should I wish a greater increase than this doubling would allow of.

Borodino, N. Y., Aug. 2.

G. M. DOOLITTLE.

Friend D., you have misunderstood us this time. We had no idea of recommending that the space for brood in the brood-chamber should be filled with honey; neither did we think of having more room in the brood-chamber than is needed. You know that, for some time back, 8-frame hives have been taking the place of 10-frame. Now, after these 8 frames are as full of brood as we can manage to get them, there will be some space for honey left around the corners; that is, when white clover opens there is generally room to put quite a little in the brood-nest without at all interfering with the brood. And this

space is usually filled before honey is stored above, especially if they are Italians. Ernest made the answer you allude to; but his idea was simply this: That we should manage to get the white honey into the sections as much as possible; and in this you are in perfect agreement with him. No one nowadays would recommend any method of management that would fill the brood-combs with honey in place of eggs and brood at the commencement of the season. In fact, the great effort and aim all along the line has been to get our clover and basswood honey into the sections. When it comes time for the bees to fill up for winter, of course we have a different matter to consider; and if we can so manage as to have only one pound or less in the brood-combs, and all else in the sections, all the better. But with us, there will probably be a pound or more scattered around near the pollen; and, of course, the pollen is to be all in the brood-combs and not in the sections.

CALIFORNIA RUNAWAY SWARMS.

AN INTERESTING ACCOUNT OF HOW THESE SWARMS WILL LOCATE IN QUEER PLACES.

THE strange homes that bees sometimes take up with in California make an interesting feature of study to the eastern visitor. In Los Angeles I saw a large swarm busily storing honey in the cornice of a large building on a principal street. Although there is a fine of \$500 for keeping bees within the six miles square of the city limits, yet this "hive" did not seem to fear it much, and the police did not arrest them in their lofty home. Perhaps it was these same bees that I saw working away on the ripe fruit in the stalls in a crowded street when in the city the other day. Do you have city bees in the East? There are more

QUEER PLACES FOR BEES TO LIVE

here. A man plowing a vineyard told me he found a swarm in a vine, and they had quite a bit of comb built. I myself have seen comb in a bush where a swarm had evidently started a location, but had become discouraged, and left. I have also seen a swarm hanging in a bunch while some of the members were bringing in pollen and depositing it in the center of the mass of bees. At such times they would defend their branch like a hive, and I like to be careful in handling a chance swarm until it is discovered whether they have located or not.

Bees often deposit honey in the rocks in California. Quite often it is in almost inaccessible places. Several have told me of seeing it run down the rocks in hot weather. There was a newspaper account, last year, of 60 tons being taken from one place in the rocks. Much of this may have been old honey that would bring but a low price. Perhaps what would strike the eastern bee-keeper as being as novel as any thing would be to find

A DESERTED BUILDING ALIVE WITH BEES,

under the shingles, in the cornice, between the chimney and wall, and odd spaces wherever they could get. We once came on a large frame farm building that had for occupants ten or eleven swarms of varying sizes, according to the space they could get to build in. We tried to take some of them that were in particularly exposed positions, but it was too near sundown, and we had to give it

up. We were at the time coming home from a neighboring village, with three or four swarms, and some honey we had taken from the attic of a hall building. The bees do not always wait for a building to be unoccupied. A sight that had quite a funny side to it was one we saw on the same trip. A "section" man on the railroad lived with his family in a house that was something like a bee-hive and dwelling-house combined. Bees were buzzing all around on two sides of the house, so that the children and everybody kept out of that part of the yard. There were, I think, seven swarms. What had been the pantry was covered with bees on the windows inside. One door was fastened up, because, should you open it, a hive of bees would be a foot above your head. We went upstairs to make an examination, and found bees in the windows inside. The whole place was wonderfully suggestive of a big bee-hive, and the human inmates had learned to take the matter as coolly as could be expected. We offered to pry the boards off and take the bees away; and although we left our address, and they were very willing to get rid of them, we have not heard from them to date. It may be because they think it less trouble to stand the bees, now that they have become used to them, than to write us a postal card. But we must go over and see about it, for I know they would thank us to take the bees away.

BEES IN CHIMNEYS.

Several have told us of bees coming down their chimneys, in their efforts to find a home. I once saw a hive with a comb in, placed on the top of a chimney to coax some bees out that had taken refuge there, and let the family breathe freely again, for they were not used to bees. It is often that bee-men are called upon here to remove a swarm of bees that have found a lodging in some dwelling. We keep a large strong cold chisel for that purpose.

It must be remembered that the dry climate here has given us a country without trees, except the live-oaks, in limited numbers. The bees have very little chance to start new homes in the trees, and must get into some building if they can, or take to the mountains. What cavities there are in the trees soon get filled with bees, and they are not large generally. We have got into the habit of calling small swarms "tree swarms," if we don't know where they came from. I could take you to a dozen trees with bees in, within a short mile of here. One is in an oak under which the public road to the railroad station passes. It has two small swarms. As the trees are valued for shade and ornament, it is rather difficult to get permission to cut into them.

We were rather pleased to see the swarms coming from the lowland to the highland at the base of the mountain, where our apiaries are. The black sage around us was just in bloom at swarming time, and it called the bees our way, and it seemed as though all our empty hives and boxes would catch bees. We had five or six on the horizontal limb of a large live-oak, with a cleated plank running down to a ledge of rocks near by; and I several times walked down that plank with a hive of new bees, direct from the Lord, so far as I could know. We got a few swarms also by putting some store-boxes, with old honey inside, in the trees.

So it came about in some wonderful way that a large apiary for a beginner has been built up. It seems very strange, when I stand in the midst of

the eager, buzzing throng of bees, scurrying in all directions, that four short months ago I knew nothing, practically, about bees. My experience then was confined almost entirely to seeing my dear mother, years ago, when I was a child, take the old-fashioned glass-ended boxes of honey from the hives. I remember with what intense delight I watched the bees and looked at the wonderful comb filled with that nectar that every child likes so well. This feeling all came back to me, just as it was then, when I saw some hives of bees at a friend's near Los Angeles, and decided to leave the strife of the city and deal not with men so much as with these little creatures which the great God had made, and which seemed to understand him better than the mass of seeking, bargaining men in the city. It would be hard to give you a correct idea of the relief with which I turned away from the strife for existence in commercial circles in Los Angeles, to watch for a half-hour these busy workers; but busy it seemed to me in an entirely different way. I never want to forget that day. I promised God, that, if he would let me have some of those pretty bees out in the beautiful clean country, I would never try to be rich again. If you have never tried to run a race with the sharp business men of a large city, be satisfied with your bees until God calls you into some other sphere.

Since our apiary has increased so rapidly in these short months since spring, there have been several critical times. But the most critical of all was when Henry and I both got to taking credit for the success we had met. During this period, before we got this feeling driven away, I believe nothing flourished about the apiary as it did before. Distrust in each other sprang up, and we might have been foolish enough to separate had we not realized where the trouble was. How strange that we should feel so humble and so happy in beginning, and that we should come near forgetting it when success came, and so spoiling it all!

We have extracted so far, up to July 20, about 27 of the 63-lb. cans. Of the comb honey, we have had but 130 lbs. This is a small showing compared with some California apiaries, and we have at times been ambitious to have several hundred stands. But perhaps we have enough for the first year. Had we more, we should not have the time we now have to spend in the study of the Bible, which is the most delightful book of all, when understood. We learn there how man came to be out of harmony with the happy order of creation, and how to get back into place again. As you may well suppose, we enjoy this study far above bee-keeping.

When I came out into the country in California there were so many new and strange things that I felt almost like a child commencing to learn every thing over again in a new world. The wonders of the mountains, the trees, and the fruit, made a deep impression. Figs, prunes, and peaches, are now ripe. We have a long stick to poke the figs down from the trees in our yard. Apricots are about gone, but the scattering ones that are left are good. The fruit is like the peach, but the tree looks like a cherry-tree. Banana, palm, pepper, eucalyptus (or rubber-tree), and many species of the cacti, are here. Geraniums grow higher than my head, and sometimes they make hedges of them. The "daisy," that the Ohio farmers are so afraid of, grows into a tree here with wood and bark.

Sierra Madre, Cal., July 24.

W. S. RITCHIE.

Friend R., like yourself I was greatly interested in the strange places that bees choose for homes in California. When I was there we found them in holes in the ground, in the dirt, and in the side of a bank; and one friend with whom I stopped was in the habit of getting a slice of honey for his dinner out of a hole in the rocks. As fast as he broke off the chunks they built more comb and put in more honey. It does me good to know that you find enjoyment just as I do, in studying God's works off alone by yourself. I like the great cities once in a while, with their crowds of human beings; but I very soon long for the quiet of my creek-bottom garden, with its beautiful little spring, and strawberry-plants with their vigorous runners ready to be trained (and almost taught what to do) by my hand. The very thought of it is restful to me; and if it were not for these enjoyments, and the restful feeling that comes to me, I do not know how I should ever bear my daily burdens and responsibilities. The man whose life is too full of business to give him time to study his Bible and to become acquainted with his God through God's works is to be pitied. I, too, poked down figs and English walnuts with a long stick. But that was in December, and you talk about figs in July. Truly one must visit California to get the hang of the many things that are so queer and strange.

FOUL BROOD.

THE FORMIC-ACID TREATMENT; THE SALICYLIC-ACID TREATMENT GENERALLY REGARDED AS A FAILURE.

Mr. Root:—As far back as 1882 I treated foul brood successfully with formic acid, being, as I believe, the first bee-keeper to use it for this purpose. At that time I had just succeeded in getting my apiary into a healthy state after a struggle of several years' duration with a most virulent form of foul brood. As I happened to have only a single foul-broody comb whereon to experiment with the formic acid, I did not feel justified in speaking or writing of it as a remedy for this destructive disease. However, in 1887 foul brood was reintroduced into my apiary from a neighbor's (in which it had been and is still rampant); and as I had a favorable opportunity of giving my new remedy a trial, no time was lost about it.

My first proceeding was to mix two teaspoonfuls of formic acid in a quart of syrup; the syrup thus acidulated was dropped on or into all brood-cells, whether diseased or healthy, twice a week, until the middle of June, when honey-storing begins in this district. An undesirable result of this rough-and-ready treatment was, that the smaller larvæ were floated out of the cells, and the loss in this way was very considerable; but every hive became healthy. To make matters sure, I fed all my bees in the autumn with acidulated syrup, the proportion of acid to each quart of syrup being doubled, or four teaspoonfuls to the quart. Although the acid flavor was very strong, the bees took it readily; and in the warm evenings, when the bees were hard at work fanning at the hive-entrances, the smell of the acid was very perceptible; and so far I can safe-

ly say an apiary was never cleared of foul brood without destroying a bee, frame, or quilt, in as short a time as in this case. I may add that a friend who keeps a dozen frame hives eradicated foul brood by the same treatment.

In regard to the trouble of using formic acid as I have described, and also the resulting loss of brood, it occurred to me to try it by pouring it into one side of a clean empty comb, which was then placed in the hive as far as possible from the entrance, and this plan of using it has proved so successful that I question whether any thing better can be devised. When used in this way, with a strong stock and warm weather, the evaporation of the acid is so rapid that the fumes, on removing the quilt, "take one's breath away" for the moment, but the bees don't seem to mind this in the least, as they cluster on and store honey in the comb containing the acid. The first thing which will strike the experienced bee-keeper on opening a hive in this condition is, that the offensive odor peculiar to foul brood has passed off; and if he examines the once foul-broody combs he will find that the bees have cleared out all the putrid matter, and that all the brood is in a condition of perfect health. A second application of the acid in this way will in most cases suffice to get a hive clear of foul brood.

As a remedy for foul brood I do not think any thing in the British Pharmacopœia is comparable to formic acid; and those who have vainly tried salicylic acid will do well to give it a trial. Curious to say, although the latter has been pronounced a failure by every intelligent bee-keeper who has tried it, it is still mentioned as a remedy in some of the bee-books published in England. For myself, judging from its high evaporating point and comparative insolubility, I do not and never did believe it possible to cure foul brood with it. On the other hand, formic acid evaporates rapidly at ordinary atmospheric temperatures, and so it is brought into the closest possible contact with every part of the interior of the hive and every part of every cell, grub, and bee, it contains. Having no offensive odor, it can be used while honey is being stored, without the slightest fear of tainting it; and, although last, not least, it is not expensive, a bottle containing 1 lb. costing about two shillings and nine pence, or less than 75 cents in American money.

The formic acid I use is known chemically as a 10-per-cent solution of anhydrous formic acid, and its specific gravity is 1.06. Bee-keepers should be careful about this, because absolute formic acid is not only expensive, but it is very dangerous to handle, the least drop of it causing very painful ulcerous sores. In fact, any solution stronger than that given above is undesirable, as it has a solvent action on the beeswax in the combs, although, strange to say, it does not affect paraffine wax.

Foul brood is rapidly becoming a serious pest, both here and in England; and if its progress is not checked it will certainly put an end to bee-keeping in these countries. This is, in my opinion, largely the fault of the bee-keepers themselves; as, when it makes its appearance, instead of trying for a remedy they regard it with a sort of Mohammedan fatalism, as something against which there is no use in striving.

In conclusion I wish to point out that, to make an experiment on the lines I have given, will cost very little money, and not more than five minutes' time; and if the necessary conditions (a strong hive and

warm weather) are present, I guarantee its complete success.

ROBERT SPROULE.

Fairview, Ireland, July 5, 1890.

We are glad, friend S., if formic acid will prove to be a germicide for foul brood. We are pretty sure from our own experience, and from reports that have passed our eyes, that salicylic acid is about so much time wasted; and the same is almost equally true of carbolic acid, or, as it is sometimes termed, phenol, in its pure forms. It would be valuable, however, if an acid could be discovered that would kill the germs of the disease, or, better still, prevent infection in healthy colonies, in apiaries where the disease exists or has existed. After all, we feel like cautioning our friends about fussing very much with acids. Let scientists, and those who can afford it, demonstrate whether formic acid is superior to carbolic and salicylic acid. Putting bees into clean hives, and compelling them to build out foundation, is an *absolute* and *sure* remedy.

WEIGHT OF SECTIONS.

MRS. HARRISON ALSO TELLS US SOMETHING ABOUT HER ENJOYMENTS.

I ASKED a groceryman last fall, who had a fine store, well stocked, and apparently considerable trade, if he wanted to purchase some honey. He replied, asking, "What condition is it?"

I said, "White clover, in one-pound sections."

He said, "What do they weigh?"

"Most of them one pound," I said. "I weighed a number of them to-day, and they were straight up and down, exactly one pound."

He replied, "I bought a lot lately that weighed a trifle over three-quarters of a pound, and that is about the weight I like. I bought them by the pound, and sell them by the piece."

I interviewed a couple of grocerymen lately, who deal exclusively in the best goods the market affords, with reference to the weight of sections. They both replied in substance as follows:

"I want them to weigh as nearly one pound as possible, not overweight, for then I lose, as I buy by the pound. In all large markets there will probably be some persons who will prefer to buy sections of light weight; but those who do a straight business will want those of full weight. Those who prefer the light weights are the kind of persons who claim to sell more pounds of sugar for a dollar than other dealers; but when you get it home and weigh it you find they have forgotten to put in the extra weight."

RECREATION.

Yesterday I baked, and made the necessary preparations to go to-day on an excursion up the river on a boat, with the Sunday-school; but circumstances beyond my control kept me at home, so I have a change by writing in the shade of a tree. Idleness is no recreation for me. As a pastime I am raising cuttings from roses, starting them in a crock of sand which I keep upon the top of a hive, in the hot sun. The sand is kept wet all the time, but no water is allowed to stand on the surface. They are putting forth new leaves now, which shows that little white roots are starting. In a few days I will put them into little pots filled with rich soil, which I will put into a box of sand, which will

be kept damp to keep them from drying out, and will exchange for larger ones as soon as their growth demands it. I save all the paper bags for various uses, and utilize all of the smaller ones to pin over nice bunches of grapes, to keep them secure from insects and birds.

It is recreation for me to study the Sabbath-school lesson in company with many millions of fellow-Christians throughout the world. The last few weeks we have been accompanying the Master in that last sad journey toward Jerusalem.

Peoria, Ill., July 22.

MRS. L. HARRISON.

Why, my good friend Mrs. H., I think ever so much more of you than I ever have before, and that is saying quite a good deal. So you really love to see things grow, as your old friend A. I. Root does. If you ever see Dr. Miller again, you just commence talking roses to him. We have a rose-garden too—a little one. Dr. Miller sent us the plants; and I tell you it is just fun to see them put out their bright new leaves, and to see them push out their little white roots. Starting things in sand always had a special delight for me. The sand is so clean, and keeping it of just the right degree of wetness during hot summer days, has a special fascination about it. There is a real inspiration in your last paragraph. It did not occur to me before, that, when we are lovingly studying and striving to follow the Master, we are really joining the ranks with *millions* of fellow-travelers. And the grandest thought of all is, that these fellow-travelers are also fellow-Christians.

BAD BOYS, AND WHY.

A FEW WORDS TO THE GLEANINGS BOYS, FROM MRS. J. HILTON.

Mr. Root:—A remark was made to me the other day that I want to speak to the GLEANINGS boys about. The remark was, "Charley J. has gone crazy, and has been sent to the insane asylum."

I could hardly believe my informant, because that same Charley was a young man we had often spoken about as being such an unusually good-appearing young fellow, in spite of the fact that he never went to Sunday-school or church, nor even to the merry-makings of the young folks. But it was proved to me that he was crazy, and, saddest of all, that the cause of his insanity was impure thoughts. Never going to Sunday-school or church, and rarely associating with Christian people, his thoughts were otherwise occupied. The old quotation, "Satan finds some mischief still for idle hands to do," should also read, "Satan finds more mischief still for idle minds to do." Dear boys, you who think it is so tiresome of mother to be so sharp after a fellow if he is not on hand to go to Sunday-school or church, they know what mischief may get into those busy, active brains, if they are not kept in the straight way; and while you are learning about God and his wishes you are not only well occupied at the time, but you are learning things that will help you when mother and father are not by to help you. Be thankful that you have some one who is anxious as to what you are doing, and pray that you may never, never feel like saying to your parents what one poor boy did whose mother always let him do as he wanted to in every thing, because

she felt it so hard a thing to vex her boy. He was doomed to death for some misdeed, and his mother went to see him in the prison; but he would not look at her, but told her that it was all her fault that he was where he was; that if she had made him go to church and other good places he would not have learned so much evil and so little good. Mr. Root tells us that he has 10,000 subscribers, and that represents 10,000 boys or more. Just think what an army of you there is! I always loved the boys, even when I was a little girl, and my love has not cooled, only grown more desirous for your good, and anxious that you should make good wise men, men whom we can point to and say, "There goes a Christian." Have you thought what that means? It means temperance men, honest men, loving, generous, thoughtful, earnest, working human beings; and it means that, although your life may be so full of work and care that it seems as though you could not do another thing, yet as God's bounty to us is like a bucket filled and running over, so even your full life may have the edges so lowered that considerable may run over to help those outside of your individual bucket, blessing not only them but yourselves in the doing.

MRS. J. HILTON.

Los Alamos, Cal., July 13.

My good friend Mrs. H., I most heartily indorse every word you have said; and I can think of no more fitting closing words than the beautiful text that all the world admire so much, whether they practice it or not: "Blessed are the pure in heart, for they shall see God."

HONEY STATISTICS

FROM ALL PARTS OF THE UNITED STATES.

In order to read understandingly the reports given below, it will be necessary to observe the following points: First, the State is given; then next in their order are the names of the reporters, with their respective postoffices. To indicate locality, the usual abbreviations are used—N., S., E., and W., for north, south, east, and west; N. E. for north-east, etc. The letter C indicates the word "central;" E. C., east central, etc. In the following list, the first figure represents the month, and the second figure the date at which the report was rendered. The small letters, a, b, c, d, etc., indicate the answers to the questions propounded in questions a, b, c, etc., just below.

On the 18th of July we prepared the following circular letter and sent it out to our statistical reporters:

Dear Sir:—It is a little early yet for many localities to render a definite report of the honey crop for the year; but it is highly important that we should know the prospects, and the probable honey yield, that we may better determine when and at what price to move off our crop.

a. What are the prospects for an average crop of honey this season?

b. What is your average yield in surplus, so far, per colony?

The replies received are as follows:

ALABAMA.

J. M. Jenkins, Wetumpka. C. 7-21.
a. None at all; b. 00,000 lbs. per colony.
W. P. W. Duke, Nettleborough. S. 7-9.
a. About 100; b. 85 to 90.

ARIZONA.

Jno. L. Gregg, Tempe. C. 7-24.
a. Good; b. about 90 lbs.

CALIFORNIA.

R. Wilkin, San Buenaventura. S. W. 7-25.
a. The season is over; 70 lbs. I count an average crop per hive here. b. The average for this season is about 45 lbs. per hive. The quality averages very fine.

Wm. Muth-Rasmussen, Independence. E. 7-25.
a. Excellent; b. about 60 lbs.

W. W. Bliss, Duarte. S. E. 7-24.
a. Very good; b. 260 lbs. comb honey.

G. W. Cover, Downieville. N. 7-26.
a. Good; b. 24 lbs.

J. P. Israel, Olivenhain, Cal. S. 7-26.
a. There is only half a crop in southern California. The season is ended; b. about 40 lbs.

COLORADO.

Mark W. Moe, Denver. C. 7-26.
a. Fair to good; b. as I have considerable honey on the hives ready to take off, it would be impossible to tell.

CONNECTICUT.

Daniel H. Johnson, Danielsonville. E. 7-22.
a. Not very good, but better than last year; b. can not average for the whole. If we count them all, the average would be about three.

Lewis Sperry, Hartford. 7-21.
a. Not very good; b. about 15 lbs.

FLORIDA.

J. L. Clark, Appalachicola. W. 7-24.
a. Nearly a total failure in this section.

GEORGIA.

T. E. Hanbury, Atlanta. N. 7-22.
a. Poor; b. 20 lbs.
J. P. H. Brown, Augusta. E. C. 7-22.
a. Prospects for an average crop are very poor; b. about 25 lbs.

R. H. Campbell, Madison. 7-23.
a. As slim as ever I saw it for the past 25 years; b. some colonies have starved. I could not have taken 10 lbs. from my 80 colonies during the whole season.

Walter McWilliams, Griffin. W. C. 7-25.
a. The spring crop is a total failure; b. could have extracted about 12 lbs., but reserved it to feed.

ILLINOIS.

C. C. Miller, Marengo. N. 7-21.
a. Very poor; b. at a rough guess, 12 lbs.
Mrs. L. Harrison, Peoria. W. C. 7-21.
a. The prospects for a total failure are good; b. with the exception of a very few colonies, which will run from 10 to 20 lbs., the surplus is nothing.
C. Dadant, Hamilton. N. W. 7-21.
a. Not good; b. 10 lbs. Too cold and too wet in early spring, and too dry now.

A. R. Goodrich, Bloomington. C. 7-22.
a. Prospects for honey this season less than 50 per cent of average crop. b. My yield in surplus to date is less than 5 lbs. to colony.

Reuben Havens, Onarga. E. 8-4.
a. Very poor; b. not to exceed 10 lbs.

IOWA.

Eugene Secor, Forest City. N. 7-21.
a. The poorest for several years; no white honey to speak of. Not 10 lbs. per colony; b. not to exceed 10 lbs.

J. W. Bittenbender, Knoxville. S. E. 7-25.
a. All dried up; b. 0.

Oliver Foster, Mt. Vernon. E. 7-21.
a. No prospect; b. none taken; perhaps 15 lbs.

A. Christie, Smithland. W. 7-22.
a. Fair; b. about 40 lbs.

INDIANA.

Mrs. A. F. Proper, Portland. E. C. 7-26.
a. Good; b. about 50 lbs.
I. R. Good, Vawter Park. N. W. 7-25.
The honey crop is a failure in this part of the country.

KANSAS.

B. F. Uhl, Boling. 7-23.
a. Not good; too dry; b. 24 lbs.
Frank H. Howard, Garden City. 7-26.
a. Good, if the grasshoppers let the alfalfa alone; b. 50 lbs., half comb and half extracted.

J. B. Kline, Topeka. E. C. 7-29.
a. Poor; b. not any.

KENTUCKY.

D. F. Savage, Hopkinsville. S. W. 7-24.
a. Early crop unusually large; b. 50 lbs.
J. P. Moore, Morgan. N. 7-22.
a. The drouth has brought the season to a close; b. 180 lbs.
Jno. S. Reese, Winchester. C. 7-21.
a. Above the average; b. 75 lbs.; season ended.

LOUISIANA.

J. W. K. Shaw, Loreauville. S. C. 7-22.
a. Poor; b. no surplus yet.
St. Julien T. Moore, Monroe. N. C. 7-23.
a. Honey crop late, but hives filling rapidly now; b. from 90 hives, extracted, average 30 lbs.

MAINE.

John Reynolds, Clinton. S. E. 7-24.
a. Very poor; b. crop not off yet. I should judge less than half a crop.

C. W. Costellow, Waterboro. S. W. 7-21.
a. Good; b. 33 lbs.

MARYLAND.

Simon P. Roddy, Mechanicstown. 7-23.
a. Poor; b. 10 lbs.
S. Valentine, Hagarstown. 7-26.
a. Not very good; b. about 25 lbs.

MASSACHUSETTS.

A. A. Sanborn, Westfield, Mass. S. W. 7-25.
a. Poor; b. I don't know.
E. W. Lund, Baldwinville. N. C. 7-23.
a. Good to date; b. 25 lbs.

Wm. W. Cary, Colerain. N. W. 7-21.
a. Prospect poor; b. about 20 lbs.

MICHIGAN.

George E. Hilton, Fremont. W. 7-22.
a. Never so poor; b. not to exceed 1 lb.

A. J. Cook, Lansing. C. 7-21.

a. The crop of light honey is almost a total failure; b. I can't say, but I don't think it is 20 lbs. I doubt whether it is 10.

James Heddon, Dowagiac. S. W. 7-24.

a. For this part of Michigan, I think the surplus crop is not over 35 per cent; b. not to exceed 35 per cent of our average yield so far; and now the drouth upon us makes our prospects for fall crop look poor indeed.

H. D. Cutting, Clinton. S. E. 7-21.

a. The poorest in several years; b. I have not taken any off; but from present indications, about 15.

R. L. Taylor, Lapeer. 7-22.

a. An indelible blank; b. 0. White clover and basswood have been a total failure.

MINNESOTA.

W. Urie, Minneapolis. E. C. 7-24.

a. I have not one pound of white honey made in boxes, and very little extracted. About the same report all over the State. Up to date, the poorest season for the past ten years; prospect good for a fair crop of dark honey; there will be no white comb honey, so far as I can learn, in the State.

A. F. Bright, Mazeppa. E. 7-25.

a. No prospects whatever; b. not a pound.

N. P. Aspinwall, Harrison. C. 7-22.

a. Good with me; b. none taken; too early.

D. P. Lister, Lac Qui Parle. W. C. 7-23.

a. Good; b. 20 lbs.

MISSISSIPPI.

Jas. M. Lewis, Osyka. Miss. E. 7-23.

a. The prospect for an average crop is very poor, owing to so much rain. The honey is very poor; b. about 45 lbs.

MISSOURI.

E. M. Hayhurst, Kansas City. W. 7-26.

a. Half a crop; b. 35 lbs. comb honey.

Chas. L. Gough, Rock Spring. E. C. 7-24.

a. None at all; b. 12.

S. E. Miller, Bluffton. E. C. 7-21.

a. Very poor; b. extracted, 20 lbs. Comb not worth mentioning.

James Parshall, Skidmore. N. W. 7-21.

a. The prospects are bad; b. we may get about 25 lbs.

Jno. Nebel & Son, High Hill. E. C. 7-21.

a. Prospects to date have been poor; good, though, for an average fall crop from Spanish-needle bloom; b. not more than 5 lbs. per colony.

NEBRASKA.

J. W. Porter, Ponca. N. E. 7-21.

a. Very poor; b. about 20 lbs.

J. M. Young, Plattsmouth. 7-21.

a. The prospect for a fall harvest is good; plenty of rain now; b. I can not give any definite result.

F. Kingsley, Hebron. S. C. 7-21.

a. Good; b. our surplus flow begins in August.

Jerome Wiltse, Falls City. 7-22.

a. The prospects are poor; b. nothing.

NEVADA.

E. A. Moore, Reno. W. C. 7-23.

a. Very good; b. about 50 lbs.

NEW HAMPSHIRE.

S. F. Reed, No. Dorchester. C. 7-28.

a. Very poor so far; b. about 25 lbs.

C. E. Watts, Rumney. C. 7-26.

a. Fair; b. have taken but little so far.

NEW JERSEY.

Watson Allen, Bernardsville. N. C. 7-24.

a. The prospect is not good; b. about 12 lbs.

J. D. Coles, Woodstown. S. W. 7-21.

a. Good; b. 50 lbs.

NEW YORK.

H. P. Langdon, East Constate. N. E. 7-25.

a. Poor, at 150 per cent increase; b. none.

G. H. Knickerbocker, Pine Plains. 7-23.

a. Not more than $\frac{1}{4}$ to $\frac{1}{2}$ a crop in this part of the State; b. not to exceed 25 lbs.

F. Boomhower, Gallupville. E. C. 7-22.

a. Very poor; b. 0.

G. M. Doolittle, Borodino. C. 7-21.

a. Poor; b. not any. Basswood is in full bloom, but it is so cold, cloudy, and windy that the bees can not work.

NORTH CAROLINA.

Abbott L. Swinson, Goldsboro. E. 7-29.

a. Poor indeed; b. none.

OHIO.

A. B. Mason, Auburndale. N. W. 7-23.

a. Poor; b. about 20 lbs., extracted.

Chas. F. Muth, Cincinnati. S. W. 7-24.

a. The honey harvest was below medium in southern Ohio and Indiana, as far as it has come under my observation; b. I don't think that the average yield per colony was 25 lbs. of honey. My own average was not quite 15 lbs. of extracted honey.

S. A. Dyke, Pomeroy. O. 7-26.

a. Very poor; b. 23 colonies, surplus 60 lbs.

Dr. G. L. Tinkery, New Philadelphia. N. E. 7-19.

a. Not favorable; b. of extracted and comb honey together, about 35 lbs.

Dr. H. Besse, Delaware. C. 7-23.

a. It has the appearance of being good; b. about 25 lbs.

OREGON.

George Ebell, Baker City. E. 7-26.

My bees all died last winter.

PENNSYLVANIA.

Thos. C. Davis, Pittsburgh. C. 7-25.

a. Prospects are not good; b. about 25 lbs.

Geo. A. Wright, Glenwood. N. E. 7-26.

a. Total failure; b. 5 lbs. 5 oz. from 130 colonies.

J. P. Watts, Murray. C. 7-22.

a. Poor; b. nothing.

S. W. Morrison, Oxford. S. E. 7-21.

a. Our honey season is over; b. about 50 lbs. comb, or 80 lbs. extracted.

A. A. Harrison, McLane. N. W. 7-25.

Worse and worse. Basswood is gone. I may get 200 lbs. white honey from 80 good colonies. June 13, only 16 had swarmed.

RHODE ISLAND.

A. C. Miller, Providence. E. 7-24.

a. Crop so far is above the average; b. about 50 lbs.

SOUTH CAROLINA.

J. D. Foshee, Coroneca. 7-21.

a. Poor; b. no surplus.

W. J. Ellison, Stateburg. C. 7-22.

a. Poorest for many years; b. about 15 lbs.

H. T. Cook, Greenville. 7-26.

a. Very poor; b. 0.

TENNESSEE.

W. H. Greer, Paris. N. W. 7-21.

a. Poor; b. 20 lbs.

TEXAS.

L. Stachelhausen, Selma. S. C. 7-22.

a. Not good; about 25 per cent; b. 20 lbs.

B. F. Carroll, Blooming Grove. 7-24.

a. Prospects good for August, for cotton; b. horse mint all plowed up; hence no more want honey near me.

J. E. Lay, Hallettsville. S. W. 7-20.

a. Bad; too wet in May and June; b. 20 lbs.

VERMONT.

A. E. Manum, Bristol. W. 7-22.

a. Poor; b. not over 5 lbs., and season ended.

F. M. Wright, Enosburgh. E. 7-25.

a. Very poor; b. no surplus as yet.

Howard J. Smith, Richford. N. C. 7-23.

a. Poor; b. 25.

J. E. Crane, Middlebury. W. 7-20.

a. Half an average; b. 20 lbs.

VIRGINIA.

J. W. Porter, Charlottesville. C. 5-24.

a. Fair average crop; b. can not report.

H. W. Bass, Front Royal. N. 7-25.

a. About two-fifths of an average crop; b. 20 lbs. comb.

WASHINGTON.

W. W. Maltby, Port Angeles. 7-25.

a. Medium; b. 50 lbs.

J. H. Goe, Mossy Rock. 7-24.

a. Good; b. 40 lbs., comb.

WEST VIRGINIA.

J. A. Buchanan, Holiday's Cove. N. 7-22.

a. Away below an average crop; b. 25 lbs.

Will Thatcher, Martinsburg. W. C. 7-21.

a. Good; b. 60 lbs.

Jno. C. Capehart, St. Albans. S. W. 7-20.

a. Of late years I am in the habit of expecting the bulk of it in November; b. I squeezed 40 lbs. from the clover yield.

M. A. Kelley, Milton. S. W. 7-21.

a. Good; b. 27 $\frac{1}{2}$ lbs.

WISCONSIN.

Frank McNay, Mauston. C. 7-25.

a. Very poor; b. 0.

J. C. Sayles, Hartford. S. E. 7-19.

a. Very poor; b. not more than 10 to 15 lbs.

S. I. Freeborn, Ithaca. S. W. 7-25.

a. Very poor; b. 20.

Joshua Bull, Seymour. E. 7-23.

a. Very poor for white honey; not more than half a crop; b. I have not yet removed any from the hives.

E. France, Platteville. S. W. 7-22.

a. Very poor; b. 4 $\frac{1}{2}$ lbs.

With very few exceptions, as we stated in our last issue, the prospects are poor, and the average yield per colony is exceedingly moderate. But as the reports were sent out a little early, as indicated in the circular letter above, it is not impossible that things will brighten up a little, even yet. In fact, as stated in the last issue, white clover seems to be hanging on in some localities, where it was expected that the yield from that source had entirely ceased. California looms up with a large crop of honey, and that means a good deal, for this State pro-

duces not a small percentage of all the honey produced in the United States. Colorado has one reporter, and he says, "Fair to good." Arizona, the State where alfalfa is produced, reports about 90 lbs. per colony. Minnesota does not seem to be uniform. In the east-central and eastern part of the State there is but very little honey; but in the central and west-central parts, the yield seems to have been good. Wisconsin, another usually good State, has also no honey of any account. Indiana, California, Arizona, Virginia, West Virginia, and Washington, report the prospects good. Almost all the rest of the States are reported poor.

If any one thinks GLEANINGS is puffing up the industry, and showing only the silver lining to the cloud, let him read the Reports Discouraging in the August 1st and present issues, and then take a glance at the Honey Statistics. As we said before, fruits will be rather scarce, and the beekeeper has not fared any worse than many of those engaged in kindred industries.

A CHAPTER ON WASPS, ETC.

PROF. COOK TELLS US ALSO ABOUT LOCUSTS, KATYDIDS, ETC.

I HAVE just received a most beautiful wasp from H. H. Hillier, Pasadena, Cal. It is a deep rich blue, with red wings. It is a digger wasp. It digs a hole in the earth, swoops down on a tarantula or other victim, stings it with its murderous sting, then bears it away to its hole. It now places an egg in its victim, and buries it. The spider is not dead, but only paralyzed; so when the egg hatches, the young, or baby wasp, has not only fresh but living food on which to break its fast. Mr. K. says they call it the tarantula-bawk. In Texas a similar wasp is called tarantula-killer. Smaller species are common here and in Ohio. While these wasps sting with powerful effect, yet I do not suppose the effect of the sting is ever likely to be fatal. These are very quick, have very hard bodies, and rarely sting one if left undisturbed. This one is very large. I am glad to get it. I should like to get many California insects.

WASPS AND BUGS.

Mr. Edward J. Knebel, Spring Branch, Texas, asks if I will describe in GLEANINGS some wasps sent by him from Texas. These are paper making wasps. They look like our *Polistes Annularis*, so common in houses in late fall and early spring. Like all of this family—*Sespedæ*—they have a longitudinal fold or a way of doubling up their front wings when at rest. We often boast of our attainments, and sneer at insects; but these wasps have built their large paper nests of wood pulp for scores—may be hundreds of years, while we have just "caught on to that trick." Like the digger and all other wasps, these insects people their cells with other insects on which the larval wasps subsist. I have often seen wasps catch and kill currant-worms, tent-caterpillars, etc. Wasps do us much good in killing our noxious insects, and do no harm except in the use of their stings, and very seldom this unless provoked to it.

CALIFORNIA COW-KILLER.

I have received an ant-like insect from J. G. Gilstrap, Hanford, Tulare Co., Cal., which is covered with thick hair, which is of a rich carmine color.

The legs and antennæ are black. The insect is very pretty. Mr. G. says, "I suppose it is a spider." He adds further, "It is rumored that it is very poisonous. Please name it in GLEANINGS."

This is one of the cow-killers. I have one illustrated in "Bee-keepers' Guide," p. 427, Fig. 216. These belong to the family *Mutillidæ*, so called, I think, because neither males nor females have wings. They are said to have a powerful sting. Possibly this is why they have taken the name of cow-killers in the South, where they are quite common. They are closely related to the ants, which they resemble not a little. In the South they kill bees. This one is a little smaller than the one that is called a bee-killer, which I have received from several Southern States. Has Mr. G. ever known of this one killing bees? This insect is very handsome, I am very glad to get it.

The larger bees with light bands and large yellow hind legs, received from Jno. Longwood, Highland, Minn., are *Melissodes Pennsylvanica*. The hairy hind legs are used to carry pollen. These bees dig holes in the ground, and put in pollen and honey, may be, as they have long tongues, and lay their eggs in this food. Thus the brood matures in earthen instead of wax cells. These bees are very handsome; and though I had them in our collection before, I am glad to get them from Minnesota. I thank Mr. L. for them.

THE COMMON CICADA (*C. tibicen*).

I have received from Mr. K. F. Beach, Olean, N. Y., a specimen of our common cicada (*C. tibicen*), with the request that I name it through GLEANINGS. This fly is just the form and about the size of the seventeen-year cicada—often called, incorrectly, seventeen-year locust. This, however, has green veins to the wings instead of red. It is probable that the seventeen-year cicada exists so long as a larva, from the habit of burrowing deeply in the ground. A taste which would make such a home pleasing would place the insect below danger, but would delay development, as both warmth and food would be too scarce for rapid development. Our common cicada, *tibicen*, I presume lives nearer the surface, and so develops, presumably, in a year. The song (?) of the male cicada is very familiar. It is the long, shrill, high-pitched rattle-like whir, heard all through the day every few minutes in July and August. Except for its higher pitch, it is strikingly like the whir of the angry rattlesnake, as I have often noticed this summer, as our rattlesnakes and the cicadæ in the oaks, just out my window, were running opposition. It is not easy to find the cicadæ, even when we hear their song, as they usually stop their noise upon our approach. Yet the other day I found one so entranced with its own music that I approached, caught it, and yet it continued its song for some time after I had it secure in my grasp. The seventeen-year cicada often come forth from the earth in multitudes, and make all outdoors clamorous with its high-pitched notes. The only harm that comes from the cicadæ is in the unskillful pruning they do in egg-laying. They cut into fruit and forest trees to lay their eggs, and often do great harm. I have seen orchards that looked as though they might have been burned, so thick were the weathered leaves on the wounded twigs. As the eggs hatch, the larva falls to the ground, which it enters, and in its cold dark home feeds daintily on roots, may be, for near seventeen years. When nearly matured it changes to brown,

active pupa, which at last comes forth, crawls up some twig or tree, splits open on the back, and the beautiful mature cicada goes forth to enjoy its nuptials with song and merry-making.

Agricultural College, Aug. 6.

A. J. COOK.

THE RATTLESNAKE THE EMBLEM OF A NATION.

SOME OF ITS PECULIARITIES; BY ONE WHO HAS
SLAIN OVER 1100 OF THE REPTILES IN
ONE SEASON.

I SEE in GLEANINGS of July 15 that Prof. Cook is delighted with his pet rattlesnakes, and wishes all of the readers of GLEANINGS could walk into his laboratory and take a peep at them. I have, perhaps, killed as many of these "varmints" as the average western man, having herded cattle in a very early day on the wide wild prairies of Central Illinois and Iowa. As my diary shows, I actually killed in one season 1100, having destroyed as many as 33 in one day. They were of the small prairie variety, but still they were poisonous, and would often bite the steers.

I wonder how many of the readers of GLEANINGS know that this reptile was at one time placed upon the flag of the nation. The great union flag of Great Britain was brought by the colonists to America; and when the thirteen colonies began to feel the pressure of British rule they placed upon their banner a rattlesnake, cut in thirteen pieces, representing the thirteen colonies, with the words, "Join or die." But when the thirteen colonies became more united in their purpose of resistance to British tyranny they placed upon their banner a large well-formed rattlesnake in the attitude of one about to strike, with these words: "Don't tread on me." The rattlesnake is truly an American "bird," found only on this continent; and how fitting the choice for an emblem! In many countries the serpent is considered as an emblem of wisdom, and, in some attitudes, of endless duration. Its eye is exceedingly bright, and without eyelids—an emblem of vigilance, and it never begins an attack; and it never surrenders, which is an emblem of magnanimity and courage. It never wounds even its enemies, till it generously gives them warning not to tread on it, which is emblematical of the spirit of the people who inhabit this country. It appears weak and defenseless; but its weapons are nevertheless formidable. Its poison is the necessary means for the digestion of its food, but certain destruction to its enemies, showing the power of American resources. Its thirteen rattles, the only part which increases in number, are distinct from each other, and yet so united that they can not be disconnected without breaking them to pieces, showing the impossibility of an American republic of the original thirteen without a union of States. A single rattle will give no sound alone; but the ringing of the thirteen together is sufficient to startle the boldest man alive. It is beautiful in youth, which increases with age. Its tongue is forked like the lightning, and its abode is among the impenetrable rocks.

This description has reference to the large mountain rattlesnake, which was known only to the Eastern people. They are many times larger in body. You can hear the sound of the rattling to a greater distance than the small Western prairie rattlesnake.

Perhaps when Prof. Cook gives the article he has promised he will tell us more about the little pets.

A GOOD MANY CRATES READY TO COME OFF.

My bees are doing fairly well. It has been almost too dry and cool a part of the time. Some late showers have started up the white clover afresh, and the bees are still at work. I have a good many crates just ready to come off. I have taken some new honey. I have had more trouble from robbers than ever before. I live near the big timber. I have thought the robbers came from there. I had two swarms come to me from there, I suppose.

Atwood, Ill., July 20.

J. W. C. GRAY.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

THE DETROIT EXPOSITION.

The following is a copy of a little slip written by H. D. Cutting, and which we take pleasure in presenting to our subscribers:

I should like to call the attention of all bee-keepers to this fact: It being an extra poor season for honey, an extra exertion must be made to secure a good attendance of exhibitors.

The Exposition Company have granted everything we have asked for—given us an extra space to show our products, the largest premium list ever offered in this country for this department, also an expert judge with a "world-wide reputation." If we do not make a good exhibit, and fill the space allotted to us, next year the list will be reduced. They have been very liberal with us, with the expectation that we are to make a large, fine, and attractive exhibit.

Now, fellow bee-keepers, do not let this be a failure, but show the people that, in the face of a crop failure, we can and will sustain the good reputation already formed, and make this a fine and attractive exhibit. If you do find it impossible to be present, and have any thing pertaining to this department that you wished placed on exhibition, you can send it by express, charges prepaid, to H. D. Cutting, Superintendent of the Bee and Honey Department, Detroit, Mich. It will be delivered to me in the building, when it will receive good care, and be placed on exhibition. Also send me instructions what to do with articles at the close of the exhibit.

Mr. W. Z. Hutchinson, of the *Review*, has suggested that all bee-keepers intending to visit the Exposition, meet "just after the judging" on the first week, and visit the Exposition in a body. You will be received by a committee at the bee-keepers' headquarters, and shown over the buildings and grounds, taking in all objects of interest. Please be with us as visitors, if you can not come as exhibitors. Bee-keepers' day will be Friday, Aug. 23.

H. D. CUTTING.

We trust that the Detroit Exposition may not be lacking in a honey display, even if, as friend Cutting says, the season has been extra poor.

HOW BEES BRUSH THEIR EYES.

Mr. Root:—In watching my bees I have noticed that every one, when leaving the hive, rubs its fore legs over the head, and so on down over the horns, or feelers. The old ones will perhaps give only one brush over, but the young bees will stand and rub for a minute at a time, the drones also doing considerable in the same hive. I should like to know if any one can tell the reason for this, as it is evidently for some purpose, as the Creator never made any thing in vain.

E. W. HOWES, M. D.

Chatham, N. Y., July 28, 1890.

We referred the matter to Prof. Cook, who replies:

E. W. Howes, M. D., wishes to know why all the bees rub their heads and antennæ with their fore legs as they come out of the hive before taking flight. It is to dust their eyes and antennæ, or "horns." Their eyes are for light, their antennæ for smell, and both must needs be clean. Hence the bees brush the eyes and dust the antennæ by use of the antennæ-cleaners. Dr. Howes can easily see that this is true by putting a bee or wasp on the window, and dropping some dust from the road, or fine chalk or flour, on the antennæ. He will see the bees use the curious antennæ-cleaners to clean the antennæ, and then the middle legs to clean the cleaners, in case it is a bee, or the jaws to do the same in case it is a wasp. The antennæ-cleaners on the front legs, described and beautifully illustrated in my book, are wonderful organs. A hollow, bearing a delicate fringe of hairs, and a duster with very fine membrane, together grasp and draw over the leg. A more beautiful and effective organ it is hard to find.

A. J. COOK.

Agricultural College, Mich.

A BIG TESTIMONIAL IN FAVOR OF THE NEW THICK TOP-BARS.

Well, Uncle Amos, the queens are doing well. One of them has proved to be an extra layer, but the other has had no chance on account of the large flow of basswood nectar, which is at this writing in full blast. It blossomed so the bees worked on some trees July 13, and it is coming in so fast that they do not stop to build comb in the sections, but cram the brood-combs full in some colonies, which is the case with one that I introduced one of the queens to July 13.

Well, I am one, perhaps, of the many who are trying the heavy top-bars, and the exact spacing I do by the use of the furniture-nails. I have 29 stocks so arranged, and am experimenting on 3 other styles and widths of top-bars on 18 different stocks, and so far I am well pleased with heavy top-bars spaced $\frac{1}{8}$, or, rather, a space between frames $\frac{1}{8}$ of an inch. I have just looked them over, and I do not find any signs of burr-combs except on two hives, and there is only a little on them. On some of my Simplicity hives with thin top-bars they have got the zinc honey-board plastered nearly full, and I tore it off and scraped off a *quart* of burr-combs. I like the slatted wood break-joint honey-board better than the zinc ones, but I am greatly in hopes that, with my new hive, I shall be able to discard them altogether. The heavy top bar that I speak of is $\frac{1}{8}$ thick and $\frac{3}{4}$ wide, and is used with my new chaff hive, which suits me better than any other hive I ever saw.

FRED C. SMITH.

Thanks for your valuable testimony. Our experience with the heavy bars has been so far exceedingly satisfactory. Did you notice, friend S., whether the colonies with thick top-bars stored less honey than the colonies with thin bars?

WHY HIVES SHOULD BE PAINTED; A GOOD ILLUSTRATION.

I have been waiting for some one to haul one of your contributors over the coals for asserting that paint does not protect wood (hives) from decay. You let him down easily by not noticing it editorially. Now, paint does protect wood by excluding moisture; and when white lead is used, the surface is hardened against the wearing effect of wind and rain. Over the old aqueduct bridge in George-

town, D. C., is a sign board over fifty years old. The old board seems never to have been painted. The bridge regulations are painted in large black letters. The face of this board (4 x 6) is so worn away by the action of the weather that the words seem to have been carved in relief, and a blind man could read by the sense of touch those raised letters which the black paint has preserved. The face of the board has left them at least a sixteenth of an inch high.

ARTHUR T. GOLDSBOROUGH.

Washington, D. C., May 28.

WHAT SORT OF PUMP IS BEST, FROM A SANITARY POINT OF VIEW?

Is a bucket pump, with buckets on that will hold a pint or more, better for the water in a cistern than the common chain pump with rubber buckets? The claim made for the former is, that the buckets carry air to the bottom of the cistern, and purify the water.

E. E. LAWSON.

Stanberry, Mo., Aug. 7.

Friend L., I do not think the kind of pump you describe has much, if any, advantage over the chain pump. The theory that carrying the air under the water makes the water more wholesome, came from the vender of a certain kind of pump; but I hardly believe it is supported by true science. Very likely the water of the cistern will be better where there is considerable agitation, as this will disturb the settlings and tend to keep them pumped out. We have had very fine cistern water during the past summer, that has been used all through the factory, in preference to any of the well-water, for drinking purposes. But this cistern water is drawn through a tin-lined lead pipe, the pipe being tinned both inside and outside; but in order to prevent settlings from getting in, the end of the pipe is turned up so as to take water a couple of feet above the bottom of the cistern. The cistern has, however, a chain pump also, out of doors. The chain pump goes lower down than the other, and is used often enough to keep the water agitated and "aerated," as the patent-pump man would term it.

A GOOD REPORT FOR THE NOVICE EXTRACTOR.

Seeing a notice in GLEANINGS, August 1, of the work done by T. H. Mills, of Cameron, Tex., with a Stanley extractor, I will state what I did for F. McNay, of Mauston, on August 10, 1889. With a Novice extractor I extracted 60 gallons of honey, hived eight swarms of bees, and did it all alone, and went seven miles to town before sundown.

Mauston, Wis., Aug. 6.

E. W. PROSSER.

Pretty well, friend P., only we should prefer to have the amount of honey stated in *pounds* rather than in *gallons*. If it is good thick honey, however, we can safely estimate 11 lbs. to the gallon. I wonder if you didn't leave things scattered around some that night.

THAT FRACAS IN OUR OWN APIARY; DOES IT PAY TO KEEP CROSS BEES?

Reading GLEANINGS for July 1, about a fracas with cross bees, in Our Own Apiary, raises the question with me as to whether it pays to keep black or hybrid bees at so great an expense of time, labor, and suffering from stings, though we have the courage to battle with them and the good fortune to survive their frequent attacks. As for me, I have

no time for all this labor and risk. Also, friend Root, how do you manage that queens are purely mated, having these black, cross, selfish bees in the apiary or vicinity with your Italians?

Mechanicstown, Md., July 11. S. P. RODDDY.

We were short of bees last spring, and accordingly purchased a few colonies of some neighboring farmers, a part of which were hybrid, and of a rather bad sort. How did we prevent the hybrid droves from mating with our young queens? Easily enough. The old hybrid queens were soon removed, and Alley traps were placed over the entrances to catch all undesirable drones. All this we have explained in GLEANINGS. But a few of the old ugly hybrid bees are with us yet. They can't do any other harm than to sting, and next year we won't be pestered with them. We would hardly take hybrids again as a gift for our purpose, though they are just as good for honey.

WHAT A BOY HAS HEARD AS A REMEDY FOR BEE-STINGS.

I have heard that, if a bee tries to sting you, and you hold your breath, it can not sting you. If this is true, it is a good discovery. I like bees and like to handle them; but sometimes they sit down too hard to please me. I like to read GLEANINGS, and some time I expect to raise bees.

Huron, Cal., July 19. ALBERT R. GILSTRAP.

Yes, we have heard this before. It is another relic of old-fogysm. The best way to prove or disprove such foolishness is to try it when bees are awful cross. Send the old foggy up here; and if he doesn't recant, it will be strange.

CAN BEES LIVE IN NORTHERN MICHIGAN?

Do you think bees would thrive here where it is not uncommon in winter for the mercury to go 15° below zero, and sometimes 25° to 36° below? It has been known to stand below zero continuously for nearly a week.

E. W. ALLEN.

Marquette, Mich., July 7.

Yes, bees will do well enough, we think. Perhaps some bee-keeper in the vicinity can inform our friend. The only trouble will be in wintering; but if you use the best methods of indoor, or even outdoor, you ought to succeed.

TOBACCO AS A BEE FORAGE PLANT.

I feel rather timid in recommending you to try tobacco. In its manufactured state it is, of course, used to the injury of many, but in its original and beautiful form I know of but few, if any, plants superior, if one may judge from the vim and industry with which the bees frequent it from morning light to close of day, from one year's end to the other, winter and summer. We have a temperate climate here, scarcely any frost, and some of the General Grant Virginian kinds are now growing spontaneously (that is, without cultivation) about my poultry-yards and stock-yards, attaining the size of trees, almost, having stems three and four inches through, and flowering every day in the year.

C. T. WREN.

Mt. Hobson, Remuera, Auckland, N. Z., March 24.

BEEES FOR RHEUMATISM A SUCCESS.

A few months ago I was troubled with a very severe attack of rheumatism, affecting principally the left arm, and almost entirely incapacitating me

from work. After practicing upon myself for about two months, with the remedies usual in such cases, and getting no relief, I concluded to try the bee remedy, and commenced applying from one to two to the part affected, three times a day. The effect was so very beneficial, that, after the first day, I was enabled to resume my work upon my place, and after two weeks I was entirely cured. I used Italians hypodermically, making them do the work themselves by holding them with a small pair of forceps to the part selected for the operation. It is needless to say, that the bees seem to understand this practice thoroughly.

Villa Franca, Fla., July 27. J. V. HARRIS, M. D.

IMPOTENT QUEENS.

Mr. Root:—The queen that you sent that lays sterile eggs is not very exceptional. I have had many such. Even a microscopic examination shows no defect. The ovaries are plump, the spermatheca full, and all seemingly in proper condition. But the eggs are impotent. This is interesting as bearing on sterility in our higher animals. It is not only necessary that eggs should grow and pass from the ovaries, but the eggs must be potent. Thus, higher animals may pass the period of ovulation regularly, and yet be sterile. The eggs in this case are sterile, or impotent.

SAND BEES.

I have three more beautiful sand bees from S. H. Crowell, Rockford, Ill. These are *Melissodes Pennsylvanica*. They are much like drone bees in size and form. They are black, beautifully ringed with light yellow. The hind legs are so clothed with hair as to resemble a brush. This enables them to gather and carry pollen. They are mason bees, digging holes for cells in the earth. Here they store pollen, in which they place an egg or eggs. They do good work fertilizing flowers. As Mr. C. requests, I write this to GLEANINGS.

Agricultural College, Mich.

A. J. COOK.

REPORTS DISCOURAGING.

POOREST SEASON FOR FRENCHVILLE, WIS.

Season for white honey is about over, and not one-tenth of a crop. So far this is the poorest season for bees, and bee-keepers too, in many years.

Frenchville, Wis., July 28.

GEO. RALL.

HONEY CROP A TOTAL FAILURE.

The honey crop is a total failure in this vicinity. It is doubtful whether the bees will gather enough to winter them. If there is a good fall crop they may pull through the winter without feeding.

Lavonia, Ga., July 26.

J. J. HARDY.

PROSPECT POOR.

The winter was severe, and the loss was about 40 per cent on account of dry and hot weather, with no dew. Bees gathered scarcely any thing from basswood. Up to date, July 10, only three swarms from 32 colonies. Fall prospects poor; in fact, it looks like a total failure.

GEO. W. BALDWIN.

Forest City, Mo., July 10.

A GOOD SUPPLY TRADE, BUT A FAILURE IN HONEY.

This has been my very best season in the supply trade. For a time I was three weeks behind with orders; and now to spoil it all, my customers will hardly get a pound of surplus honey to the colony,

as the season is almost a total failure, and very many of those who were so enthusiastic a month ago are disgusted with the whole business. This is the fourth year that the white clover and basswood have failed to secrete honey. A. B. HERMAN.

Burnett's Creek, Ind., July 25.

CROP WILL BE LIGHT.

Our crop of white honey here on the Mississippi bottom will be very light. Clover never promised any better, but we had one hot week the last of June, and the bees don't seem to get any honey from it since. Basswood is about done blooming. Bees get honey from it early in the morning, but very little comes in through the day.

Savanna, Ill., July 11.

JOHN HANDEL.

UTTER FAILURE OF THE HONEY CROP.

Bee-keepers in this vicinity report an utter failure of the honey crop. There are plenty of flowers, but there is no honey. We never had a better outlook for honey than we had in fruit and dandelion bloom. The bees began storing then, but they have been making only a living since then. There was an abundance of white clover here, but it yielded no honey; and those living along the timber reported no basswood honey. Bees are very strong, but they consume all the honey they gather. If fall bloom does not yield more honey than we have had so far, we shall have to feed our bees for winter; but I look for a better fall, as there is lots of buckwheat in this vicinity. Bees swarmed but very little here. The honey crop is reported better in the south part of the county, and swarming was better.

O. D. NICHOLS.

Owasa, Ia., July 26.

REPORTS ENCOURAGING.

BEST SEASON EVER EXPERIENCED IN MASSACHUSETTS.

This has been the best season for clover that I ever experienced. It is so dry now, however, that the bees are robbing, and cross as blazes. If we don't get rain soon, our buckwheat and fall honey will amount to nothing.

ALLEN LATHAM.

Lancaster, Mass., July 24, 1890.

A BEGINNER'S SUCCESS.

One year ago last spring I had one swarm of bees given me. It swarmed three times, and the 20th of August they had no surplus honey, and last fall we took from them 256 lbs. of honey, most of it being in pound sections. The honey was very nice, and looked like white-clover honey, but it was made from horsemint. I now have 15 swarms of bees, so I begin to think I am a bee-keeper, though they have no surplus honey now.

CARRIE KESLER.

St. Anne, Ill., July 30, 1890.

A GOOD YIELD FROM BASSWOOD AND CLOVER.

In this locality the bees have had plenty of clover and basswood to work upon, and I have hives that have already, no doubt, 100 lbs. of clover and basswood honey stored in 1-lb. boxes. But the increase with me has been very small. I had 7 old colonies, all strong, I placed the supers on early, and have, for the number of swarms, lots of honey, but only one new swarm. This may be peculiar to my bees, and the way I have dealt with them, as my neighbors have had, some of them, quite an increase.

The honey is superb, and clover and basswood not gone yet either.

MILTON L. BISSELL.

Gerry, N. Y., July 28, 1890.

OUR QUESTION-BOX.

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 166—1. Can I, by feeding, raise as good queens before the general swarming season as during that time? 2. Can as good queens be raised after the swarming season?

1. 2. Yes.

Ohio. N. W.

A. B. MASON.

Yes, every time.

Ohio. S. W.

C. F. MUTH.

1, 2. Yes, if the colony is strong.

Illinois. N. W.

DADANT & SON.

1. Doubtful. 2. Still more doubtful.

Ohio. N. W.

E. E. HASTY.

1. Yes, I think so. 2. I say yes.

Ohio. N. W.

H. R. BOARDMAN.

Theoretically, no to both. Practically, yes to both.

Michigan. C.

A. J. COOK.

I should slightly prefer queens reared in swarming time to those reared either before or after.

California. S. W.

R. WILKIN.

1. I do not think you can, quite. 2. Yes, they can or can not be, according to circumstances.

Michigan. C.

JAMES HEDDON.

1. Yes, but attend closely to the feeding; feed regularly every day, and have the hive or nucleus box full of bees. 2. Yes, by the above plan.

Vermont. N. W.

A. E. MANUM.

Some of our best queens have been reared either before or after swarming; but as a rule they are not quite as uniform.

New York. C.

P. H. ELWOOD.

Yes, to both, if you put the colony rearing queens in the same or a similar condition to what they enjoy during the swarming season.

New York. C.

G. M. DOOLITTLE.

1. Yes, if your colonies are strong enough and weather is warm enough. 2. Yes. If the conditions are favorable, just as good queens can be raised in August, or even September, as earlier.

Illinois. N. C.

J. A. GREEN.

I don't know. I have never raised queens after the middle of July; but having so many young queens to clip every spring, I know that the bees do supersede some queens after the middle of July. As for the goodness of those late queens, I think they are all right.

Wisconsin. S. W.

E. FRANCE.

Yes, select your strongest and best colonies, and by regular and systematic feeding stimulate them to the swarming-point. The best queens we have ever had were raised that way. 2. I can not speak

positively; but reasoning from general principles, I should say not.

Illinois.

MRS. L. HARRISON.

I doubt whether as good queens can be raised either before or after as during the swarming season. Still, if the bees are fed bountifully, and the weather is favorable, it is possible that good queens can be raised any time.

Illinois. N.

C. C. MILLER.

I think not. Weather is too changeable, and I doubt whether we can supply to the bees, when confined to the hive, food for queen-rearing that will equal that which they are able to provide when weather is warm, and they are flying freely. 2. Yes, with good weather and plenty of honey coming in. What is to hinder?

Wisconsin. S. W.

S. I. FREEBORN.

Just as good and just as prolific queens as I ever had in my yard have been raised at both extremes of the season. Liberal feeding and favorable weather are needed. This season, 1890, with us has been so cold that queens could not be raised to advantage. Hot weather and a good flow of honey, or feed, and care on the part of the apiarist, is all that is necessary to raise good queens.

New York. E.

RAMBLER.

I am glad to see so many of the opinion that just as good queens can be raised outside of the swarming season, and I am glad, too, to see so many suggest that all the conditions must be complied with. The finest queens I ever reared in my life, and the most satisfactory work in building up colonies I ever did, was during August and September, when we were compelled to keep things moving by daily feeding. Of course, bees got pollen plentifully from corn and other sources; but they obtained so little honey that brood-rearing would have stopped almost entirely had it not been for the daily rations of sugar syrup. Nature is good; but the keen, energetic, and enthusiastic student of nature can make nature boom in a way she rarely if ever does boom without man's assistance.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

STINGLESS BEES AT THE HOME OF THE HONEY-BEES.

Two or three weeks ago we were notified that a box of bees was at the express office. As they had come from Cuba, we supposed, of course, they were all dead, and were questioning whether we should accept them. We pried off the cover, and on peering through the perforated tin we saw, not a lot of dead bees, but a few dozen little insects that looked very much like what we call "sweat bees." Surmising that they might be the stingless bees, we accepted them at once. Mr. Spafford and I did not know what to do with the things. I was a little afraid that they might not be able to defend themselves against the ordinary Italians; and although they were stingless, I had read somewhere that they could bite fearfully hard. Mr. Spafford was requested to

fix them up and make the entrance so narrow that the ordinary bees could not pass through. In the mean time the following letter came to hand, which explains itself:

Mr. Root:—With this I send the stingless bees that I wrote you about. I hope they will reach you in good condition, as they are queer little fellows. Some time ago we had ten days of very rainy weather, and the top of the box that they are in had a large crack, and let the water into the box. When the weather was good I went out to see my bees, and I noticed that these little fellows were bringing water up to the door, each one two drops at a time; and as fast as one would back into the hole there would be another. I took off the top, and, to my surprise, found it about half full of water. They were pumping it out as fast as they could. There is not any thing known about these bees. No one has ever seen them swarm. These have been in this box ten years. You will see that at first it was a one-story; but as they filled that up to give them more room, the other piece was put on. I hope you will be able to enlighten us about them.

Havana, Cuba, July 16.

JAMES WARNER.

Yes, indeed, they are "queer little fellows." We caught a few and found that they could not be made to sting, and for the very good reason that they *could* not use a weapon that they did not have. The facts related by friend Warner are interesting. Just think of those little fellows carrying the water out, one by one, in little bits of loads from the bottom of their box! When the box arrived I noticed that it was a little damp inside, and this was doubtless because of it. No, friend Warner, there is not very much known about these bees. In some of our back numbers, two or three subscribers have mentioned seeing them in Mexico and elsewhere. I have been vainly looking over the indexes in our back volumes, but I fail just at the moment to find any thing regarding them. I have, however, been watching them very closely.

I will say to our readers, that these bees are about two-thirds the size of the ordinary Italian bee; and as I said at the outset, they look very much like our sweat bees of the North. On the whole they are rather pretty and sprightly, and exceedingly quick on the wing. What they lack in a sting is made up in powerful mandibles, or jaws; and I amused myself considerably by poking long timothy straws into their entrances, to see the little fellows get hold of the grass and fairly bite it in two; and when their jaws went together I could hear them snap. I wanted to put my finger into the hole and feel them bite, but I could hardly scrape up courage enough. Finally when a friend came around I called him up to the hive and told him we had some stingless bees, and suggested the propriety of putting his finger in at the entrance, to see what they would do. Nothing daunted he did so, but they seemed to think there was no use wasting their strength on such a big object, and simply backed into their hole and allowed his finger to remain unmolested. After assuring myself that they would not hurt *him*, I tried it. Very soon some of our Italians began to buzz around, because the box had a strong odor of Southern honey. While

watching I noticed a big fly come up and peek in at the entrance. He had no sooner done so than one of the little fellows jumped out like an arrow, and Mr. Fly absented himself, and that right speedily. I took up an Italian, disabled him, and put him in at the entrance. The little stingless fellows seemed to recognize that he was crippled, and so they simply pushed him out, as they did others that I put in in a similar condition, for I could not get a bee not crippled to even smell at the entrance. One day, while I was chancing to go by, I saw an Italian down in front of the hive. One of the stingless bees was on its back, and with its powerful mandibles was nipping away at the little cord which connects the abdomen with the thorax. I did not see him bite it in two, but he gave it such severe pinches that the bee from Italy finally gave up struggling, and very shortly afterward died. Whether this is a trick of the stingless bees or not, I am not able to say. If so, it is exceedingly cute; and it is something that I wish our Southern subscribers, or those who are favorably situated, would report upon. Be that as it may, we have not been at all afraid that any thing would rob them. They seem fully able to hold their own.

WHY NOT PUT THEM ON MOVABLE COMES?

Later in the day, after they were received, I told Neighbor H. that we had just come in possession of some stingless bees. He asked me a number of questions, but I could not give him any thing very definite then.

"Why don't you transfer them," he said, "and put them on movable frames?"

"Come with me and I will show you why we don't."

"Why," said he, "they build their nests about like bumble-bees."

"Yes, only more so," I replied.

Their honey-cells are about the size of walnuts, and very much the same shape. They seemed to be in a jumbled-up mass in the center of the hive. Clear down in the center, through a slight opening, I noticed that they had brood-cells about the size of peas, very much in the same mixed-up condition. Their honey-cells will hold perhaps a couple of ounces of honey.

ARE THEY OF ANY PRACTICAL UTILITY?

Although I have been watching to see whether they bring in honey, I have not yet been able to discover that they do. On the contrary, scarcely a bee emerges from the entrance. There can not be more than four or five dozen bees in the whole colony. It is true, we have not been having honey coming in to any extent; but on the day they came, and two or three days after, the Italians were gathering quite a little honey. It would seem that they have gathered all that they think they will need in their southern home, Cuba; and as their numbers are comparatively small, there is no immediate danger of their starving. I am sorry that all our readers can not see them, because they are really interesting if not really serviceable to man.

THE DIBBERN BEE-ESCAPE.

Our later experiments with the star-shaped horizontal escape were not very satisfac-

tory. There were too many openings, and the consequence was that the bees would find it and get back through. Still another trouble, the openings were too small, and drones and workers would clog the thing up and shut off the openings altogether. Mr. D. and myself have been having some correspondence back and forth. The result was, he sent me an escape that had only one opening. It is like what we originally illustrated on page 5, 1890, being pear-shaped. The openings in this were much larger, and I am pleased to say that so far it seems to be a success in every way. It will rid an extracting super of bees in short order. It does not clog up, and so far promises to be a success. The first time I put it on the hive I made a mistake and put it on upside down. The result was, that almost all the bees abandoned the brood below and went up into the extracting super above. A few hours afterward we turned it the other side up; and when we came to examine afterward, we found scarcely a bee in the super. I hope that Bro. Doolittle will try one of these later ones.

NOTES OF TRAVEL AMONG YORK STATE BEE-KEEPERS.

FROM MEDINA TO BORODINO.

I start to-day, Aug. 6, on my trip among the bee-keepers of the Eastern States. I take the train to-night, and go as far as Syracuse, when I expect to get off and make the rest of my trip through York State on the Victor wheel. I may be very sick of wheeling or bad roads. If so, I shall seek the aid of the locomotive; but it is a fair average for bicyclers to make about 50 miles a day, with reasonable stops, on fair roads. Day before yesterday morning, before breakfast, I took a run of twenty miles in two hours and ten minutes. I enjoyed my ride exceedingly; and after taking a refreshing drink of new milk, and after eating a little cracked wheat, I felt ready to take another run. This distance was made over somewhat hilly country. I say this, that those of our readers who are unfamiliar with what may be done with the high-grade bicycles will not conclude that I am rather foolish in undertaking what may seem to them a wild and impracticable scheme. One of our employes, Mr. Jacob Borger, traveled last summer 400 miles; and after finishing the last mile he seemed to be as hale and hearty as when he started out. So much for the improvements that have been made in cycling within the last seven or eight years. I hope it won't rain. If it does, there are some bee-keepers I may not be able to call upon.

Wednesday, 6th.—Here I am waiting for the train at Medina, rigged out in a bicycle suit; i. e., a blouse, black shirt and tie, with short knee-breeches, black stockings, and low cloth shoes. I wonder if it is undignified to visit bee-keepers in such a habit. No, I am sure it is not. For cycling I need a light and cool suit, and trousers without any flopping edges to catch in the spokes of the wheel or pedals. Besides, I have

strapped to the machine an ordinary suit of clothes for Sundays, and—yes, there is the Kodak under the seat. There goes the whistle, and the train is here. Jacob, who traveled 400 miles last summer through Michigan and Ohio, is ready to help me get the wheel on the train, for most companies won't check bicycles. There, the train is moving, and I scramble for the car-steps. Father gives me a paternal grasp of the hand, and looks a little worried. Mother remarked at the table that she was afraid that I would overdo on the bicycle; or, from the frequent change of drinking-water, become sick. Perhaps father is thinking of the same thing. I will be very careful.

I am in Cleveland now, and my bicycle has been checked as far as Buffalo, on the Lake Shore. The agent says he doesn't know whether the N. Y. C. will or not from Buffalo to Syracuse. I get a sleeping-car ticket, and then delight (?) myself with the thought of how nice it will be to get up from the sleeper a little after midnight to have my wheel re-checked or something else.

I don't sleep very well, for fear the sleeping-car porter will forget to wake me up at the proper time. I yawn and stretch, and think how nice (?) it will be to make a bicycle trip from Syracuse among bee-keepers, with my wheel in Buffalo. The weary hours wear by, and finally, by squinting at my watch by the dim light, I guess it is about time to get up. I am all dressed when the porter punches and says, "Hurry up and get up, boss, for we're near Buffalo." The train has no sooner stopped than I glance at the name of the car I am on, and then run forward to the baggage-car. The train waits but a few minutes, and the baggage-man says the wheel can't be taken if there is lots of baggage. I hang around and parley with him while I try to keep watch of my sleeper, which I see is switching on to another track. Finally the railroad official asks for the check on the bicycle, which had been put on by the Lake Shore Co. Oh dear! *oh dear!* I can't find it! Yes, here it is. I remembered then that Jacob said, "If the agent is 'obstreperous,' offer him a quarter." I did so, and then handed him another quarter to take good care of it and not bang it around. The baggage-man is very obliging. His face shows that there is *plenty* of room in the car, and that he will see that it is safely delivered in Syracuse. The other baggage-man called out, "You didn't give me no quarters, and I brought it to Buffalo."

"Yes," I say, "but your company checked it." I have no time to settle with another man, for my sleeper is—where? I am on the other horn of the dilemma; viz., a bicycle in Syracuse, but the rider still in Buffalo. I race up and down that immense depot, looking for a sleeper with the right name. Over there is one just going out on the end of a long train. Yes, it is the right one. In a few minutes I am asleep, because both horns of the dilemma are out of the way.

Thursday, 7th.—I am in Syracuse on my bicycle, both of us unharmed by the contingency of the night before. The roads and

scenery are beautiful. The wheel makes not the slightest noise; and if ever I felt enchanted, it is on this bright cool morning, flying, as it were, to Skaneateles, 25 miles distant.

13 MILES OUT.

Oh dear! There's a hill a mile long, and a steep one; and, worse than all, it's stony and rough. I dismount and push up hill. I don't feel very much "enchanted" now. The sun is hot, and I am sticky with sweat, and the exhilaration of "flying" is well nigh spent. I am on top of the hill now, and am spinning through the country. It's lots of fun to cycle.

AT SKANEATELES.

I have gone 25 miles in a little over three hours. I am not fatigued. The beautiful Skaneateles Lake is spread before me. The air is delightfully fresh after a ride. The water at the dock is as clear as crystal, and I can see good-sized fish in the water 12 feet deep. A beautiful little steamer will leave soon, and I board it for Borodino, the home of G. M. Doolittle. On the right are pleasure-resorts on the rising shores; over to the left is Borodino. It looks as if it might be a pretty place. It's too dark now, or I would take a photograph with the Kodak.

ERNEST.

TOBACCO COLUMN.

THE INFLUENCE OF THE TOBACCO COLUMN IN THE FAMILY.

I notice in GLEANINGS that you give a smoker to any person who stops using tobacco. I have stopped, and I thought I would ask you to send me one. I agree to pay you 75 cents for it should I again commence. My father is a subscriber to GLEANINGS. He has about 20 colonies of bees, and a smoker would be a welcome present.

Waverly, Neb., June 20.

CHAS. D. GILLHAM.

I like your efforts to get people to quit using tobacco. After seeing your offer to give a smoker if any one would quit using tobacco, I have made up my mind to quit using it in any shape; and if I ever break my pledge I will send you \$1.00 to pay for it.

Darien, N. Y., July 1.

F. L. WOTTON.

PLEDGES NEVER TO USE THE WEED AGAIN.

Mr. Virgil J. Seymour, who is a man of 60 years, pledges himself never to use tobacco in any form. Please send him a smoker; and if he uses the weed again he pledges himself to pay for the smoker.

Nunica, Mich., July 3.

MRS. E. C. REID.

ONE WHO HAS USED THE WEED 20 YEARS, AND QUIT.

Having taken more interest each time I have read your Tobacco Column, I have made up my mind to give up the use of tobacco. I have used the weed, in smoking only, for the last 20 years, and will pay you for the smoker if I touch it again.

Sydney, Australia, June 3.

N. LEROY TRACY.

I have quit the use of tobacco, and I promise to pay for the smoker if I ever use it again.

Camden, Mich.

FRANK KUNKLE.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

That art on which a thousand millions of men are dependent for their sustenance, and two hundred millions of men expend their daily toil, must be the most important of all—the parent and precursor of all other arts. In every country, then, and at every period, the investigation of the principles on which the rational practice of this art is founded ought to have commanded the principal attention of the greatest minds.

JAMES F. W. JOHNSTON.

QUITTING THE BEE-BUSINESS AND GOING INTO GARDENING.

A FEW days ago notice was received from a postmaster somewhere away down in Texas, saying we need not send GLEANINGS any more to a certain bee-friend at his office. I think that the postmaster said that this friend had gone into other business, but I don't quite remember. I do remember this, however, that the postmaster, for some reason or other, inclosed a photograph, and a copy of this photograph we submit to our readers.

legend inscribed, "First Credit Foncier Bee-hive." If 12 onions weigh 18 lbs., these white onions weigh $1\frac{1}{2}$ lbs. or more. In our market such onions would bring 10 cents per lb. in July, and we have been selling them at that price for nearly a month past. Ours are the White Victoria. We sowed the seed in the greenhouse, and planted the onions in the open ground as soon as the frost was out of the ground so it could be worked readily. Two rows only 150 feet long gave us six bushels of these great onions. As six potatoes weigh 6 lbs., they average a pound apiece. During the month of July such potatoes would have brought 4 cents per lb., or perhaps nice specimens like the above would have brought a nickel apiece. With us, carrots are slow sale; but perhaps we might have got 1 cent per lb. for them. Now, if our friend has as good a market as we have, he perhaps is doing a fine thing in gardening. It should be remembered, however, that these prices are to be obtained only by carrying the vegetables fresh from

GIVING UP BEE CULTURE AND GOING INTO GARDENING; BEETS, ONIONS, POTATOES, AND CARROTS.

You will notice that all these vegetables are piled up against a bee-hive. You can not get much of a glimpse of the hive on account of the vegetables; but by the way the cover is cleated we infer that our friend has read the journals and kept up with the times. Right under the cover we find the

the ground right to the people's homes. Our land is inside of the corporation of a town of 2000 inhabitants. I have told you how we get our good prices. Most of you know that green corn is very much nicer when taken directly from the garden right to the kitchen stove; therefore one of our boys gets up

at five o'clock and gathers the green corn for the wagon that starts out at six. People have found out that *our* corn is just from the stalks, and they willingly pay us 12 cents a dozen, even for small ears of early corn. Large onions, large potatoes, nice fresh corn, and other things to match, bring good prices. May I suggest to our friend, however, that if I were in his place I should not be in haste to abandon the bee-business. Don't make your hives into kindling-wood just yet, as you see our friend doing on another page. Take good care of them, even if they don't pay now. Don't buy any new traps or fixtures. In fact, don't pay out any more money until there is a better prospect of some money coming in. Of course, I wouldn't let the bees starve. Feed them during poor seasons when they may be likely to be out of stores, and keep them in reserve. When the onions and potatoes and carrots do not pay very well, just as likely as not bees will pay tiptop.

down to one or two kinds, instead of the great string of varieties we find in most catalogues. Let us take wax beans for instance. Wardwell's kidney wax beans, at least in our locality, are in every respect superior to any thing else in the way of wax beans. They are larger, and so free from rust that you will not find a specked pod in a whole bushel—absolutely stringless, and more productive than any other bean we have ever raised. To-day I picked 16 great beautiful pods, as handsome as wax work, off from one beanstalk. This is the product of a plant from a bean dropped when we were planting beets. It is a great relief to us to have only this one kind. We have for weeks been getting 50 cents a peck for them, and they are going off now by the bushel, at 30 cents a peck. What is the use of so many varieties? We are proposing to cut our seed catalogue for 1891 down to fewer varieties than ever before; but in order to do this intelligently, we are testing

THE REASON WHY FRIEND TERRY GOT \$4.00 A BUSHEL FOR HIS STRAWBERRIES WHEN OTHER FOLKS COULD NOT GET \$2.00.

The picture above, which is from a photograph, illustrates the truth in our heading. Friend Terry had pictures of drawers of different kinds of his berries made for the strawberry-book; and while doing it, the idea suggested itself of taking a drawer from the stock in front of one of the groceries, and putting it side by side with his own. Although the picture is not a very good one, it tells the story. On page 502 I gave you an illustration of the way in which his berries sell while the market is glutted with the common kinds.

RAISING FEWER KINDS OF VEGETABLES.

It is a very great relief to me, and doubtless will be to many of the friends, to come

almost every variety offered. Just think what a relief it will be to have one kind of tomatoes, one kind of wax beans, two kinds of lettuce, three kinds of cabbages, two kinds of corn, two kinds of cucumbers, two kinds of muskmelons, same of watermelons, two kinds of onions, three kinds of peas, three kinds of radish, two kinds of squash, two kinds of turnips. I do not know that we shall be able to cut down quite as close as the above, but we are planning to come pretty near it. There may be special circumstances requiring different varieties for different localities; but perhaps a bright, wide-awake seedsman in each different locality can help this matter to some extent.

OUR HOMES.

But he said, Nay; lest while ye gather up the tares ye root up also the wheat with them.—MATT. 13: 29.

A FEW days ago I went up into our swamp garden. Owing to the cares of building, and other cares combined, I had not been up there for some time. But as the onions had been thoroughly weeded only a short time before that, I concluded that nothing could be suffering *very* much. To my astonishment, however, the whole piece of ground was literally matted with great plants of purslain. One would wonder how one little root could produce so great an amount of foliage, and I began to conclude that purslain must be a sort of air-plant; that is, it gets largely of its sustenance from the air and rain as well as from the medium of the root. The onions were making a splendid growth, but a great many of them were getting badly choked. I like to pull out purslain, because we get such a great amount of weeds by pulling up only one very small root. These roots were branching, however, a great deal like the tops, and the rich black soil was so loose that, when the weeds came up, out came with them several nice onions. The onions were of the new Victoria, that I have told you about, and they came up so white and beautiful that it really seemed too bad. But, what was to be done? That purslain must all come out of the swamp *before night*. I called the hands and instructed them to hold the onions down very carefully while they pulled the weeds out. By using care and patience the onions would be harmed but very little. But if one went at it with a rush, and just scraped the "pusley" up by the armsful, the onion-patch would be almost ruined. While deciding what to do, the text at the head of this lesson came to my mind. Oh how much need there is of careful people in this world—of careful boys and girls! How I do love them! In order to be careful, one needs to have a love in his heart for his work. Somebody who is enthusiastic in gardening, and loves to see the onions grow, would probably, without instruction, get the weeds out without making mischief. And so it is, dear friends, in weeding out the sin and evil that are to be found in this world—yes, in these daily lives of ours. I am inclined to think that most of those who read these pages are called upon daily, perhaps hourly, to instruct others, to rebuke and to reprove sin, and very likely to take to task those who have been remiss in duty. Oh what a glorious thing it is to have the spirit of Christ in our hearts—to have the grace of God uppermost when we undertake to right wrongs!

Let me give you some samples in daily business. There are certain things that greatly annoy and vex our clerks here in the office. Yes, and these things also annoy and vex the great world at large, more or less, also. Perhaps no one thing occasions more vexation here than to have people order bulky or heavy goods by express, and then refuse to take them when they get to

destination. I have told you before that, in order to facilitate rapid transit, we obligate ourselves to pay every bill of express charges on every thing we send out—that is, where the consignee *refuses* to pay; and our clerks have had so many trials and losses in this line that perhaps they are almost *too* ready to stand up for our rights. If one even *thoughtlessly* orders something by express that ought to go by freight, if he is not a responsible man it will, of course, be like any other transaction—he can not be made to pay for what he has ordered unless he chooses to. If the goods are refused, in due time the express company notifies us of the fact, and asks for a disposition, and presents a bill of charges. Now, if the man who orders the goods would write and tell us that he had refused them because the charges were more than he expected, it would make the matter better. But usually he refuses to pay the charges, and there drops it. We write and write; and when we can get no answer we ask the postmaster about him; then perhaps the commercial agencies hunt him up to see whether he is responsible. If the amount is considerable, an attorney sometimes needs to be employed in the case.

What has all this to do with the Bible text? you ask. Why, this much: In these days of Endeavor societies, young people's weekly prayer-meetings and revival times, it often happens that the one who ordered the goods is a Christian—perhaps a young convert; and I hardly need tell you that nothing quenches the spirit of Christ in the heart of a young convert like a quarrel—perhaps a lawsuit. Where one has *fairly started* out on the road from earth to heaven, something of this kind may cause him to settle back and give it all up. Now, then, how shall we take him to task for putting us to the trouble and sometimes large expense by his own thoughtlessness? Our usual way is to wait 30 days, or until the express company notifies us that the goods are lying at destination, uncalled for. Then we write the one who made the order, asking him why he refuses the goods, explaining the circumstances. If he still refuses to pay the charges after we have traced them up to see that they are correct, we then tell him that we hold his order in plain black and white, with his signature at the bottom, and that we shall have to *hold him* to his contract if he is worth enough to be responsible. Now, this is right and proper. As a rule, it does the young Christian, or *anybody else*, good, to hold him to his contracts. One can not be a Christian, nor even a fair business man, and repudiate his promises made in plain black and white. But the trouble with us here is, that we are in too much haste to take it for granted that somebody means to beat us out of our money. Then we go to work straightening him up, as I went to work pulling the purslain out of the onions. Our friend is made angry, and becomes soured toward us and toward the express companies also. If he is starting out to be a Christian, he may be soured toward Christ Jesus, and may be lost, and never make another start. Think of comparing

for a moment the loss of a few cents, or even a few dollars, to the loss of a soul!

We were recently notified by an express agent in Colorado that a package with a considerable amount of expressage on it was refused. We accordingly wrote as follows to the one who ordered the goods:

E. M. Beckwith.—

Dear Sir:—We understand from your agent at Rye, Colorado, that the package we shipped you June 23 is refused by you on account of excessive charges. You should have acquainted yourself with the expense of shipping before making the order. We filled the order just as you gave it; and in order to have express shipments forwarded promptly, we have to guarantee charges; and if you do not pay them, it will come back on to us, and we in turn will have to get it out of you some way, if possible, if you are worth it. You might just as well save all this trouble by accepting the package and paying the charges, and learn a useful lesson by which you can profit in the future.

It seems, however, that the express company had been hasty as well as ourselves. In due time comes the following letter:

Mr. Root:—In your understanding that I refused to pay the charges on your express packages, you are not correct. I never refused to pay the charges, but simply said that they were excessive. The package lay in the office during my confinement by sickness, some two weeks, but I sent the money to the agent before I was able to go for the packages. I had Mrs. Ellwell, of Pueblo, send last spring, a year ago, for your hives and fixings, which I am using. But your fear that you can not make the charges out of me will prevent me hereafter from getting my friends to patronize you, lest their deal with you be no better than mine.

Rye, Col., July 30.

E. M. BECKWITH, M. D.

You will see from the above that our friend did not refuse to take the goods; and, furthermore, that he has been for some years a friend of GLEANINGS, and has induced different individuals to send orders to us. No wonder he felt provoked when he received such a sharp letter as ours, simply because sickness prevented him from going to the express office. Do you not see how much better a mild letter of inquiry would have been in the first place?

You will notice that the letter opens up with "Dear Sir." Most of our correspondence, as you may have observed, commences with "Friend." But as we were vexed because the goods were refused, as we had been told, I presume the "Dear Sir" accorded more with our feelings. Looking back at the transaction now, it is very easy to see how much better something like the following would have been:

Friend Beckwith:—We are told by the express agent at your place that you have refused the package of June 23, on account of excessive charges. Perhaps you are not aware that we shall have to pay these charges if you do not. Of course, we do not know you; but we can hardly believe that you would willingly let the whole burden of this expense fall on us when we simply did exactly as you directed us to do. Will you not please let us hear from you at once?

Now, if such a letter as the above would not bring a courteous and gentlemanly answer, then it would have been time enough to suggest to him that he was legally responsible—that is, if he was a responsible man—for the consequences of his blunder if it was a blunder.

A little incident in the papers a few days ago read something like this:

A little girl propounded a question to her mother.

"Mother, which do you think is the worse—stealing, or telling lies?"

Her mother was somewhat puzzled, and asked her little daughter what she thought about it. She replied something like this:

"Why, I rather think that telling lies is worse than stealing; because, you know, if you steal any thing you can carry it back or pay for it; but if you tell a lie it just stays there for ever."

Now, my friends, there is a sad moral to the wonderful truth expressed by the little girl. We can atone for the loss of property by an apology; but when we hastily give way to the temptation to speak harsh or unkind words—words that cut and sting—it is a pretty hard matter to take them back. The express company thought it very likely that our friend refused the goods because of the excessive charges; and we, in a like manner, took it for granted that we had got to pay the tremendous express charges this long distance, and then get them home the best we could. "Is not easily provoked; thinketh no evil." What a grand little text this is, in view of matters like the above! Below is our letter of apology, but we feel that it will hardly heal up the wound we unwittingly gave to a friend of ours:

Friend Beckwith:—We beg pardon for having worded our letter quite so strongly. We have had quite a little trouble recently with parties refusing express shipments because they thought the charges too high; and from the way your agent stated the matter, we thought you presented a case of the same kind. We are glad to know that in this we were mistaken, and beg your pardon for having accused you falsely. We trust you will not cherish any ill will toward us because of this.

Another productive cause of trouble is *returning* goods without first writing to us and asking what disposition to make of them in case they are not wanted. It is very expensive shipping goods long distances, either by express or freight; and our trade is scattered so thoroughly that we can almost always order, to somebody near by, a thing that is not wanted, and thus save losses; whereas if the goods are sent back here, we are obliged to pay transportation two ways if the mistake is ours. If the mistake is our customer's, he is needlessly out of pocket; and I do not feel a bit better to see somebody else lose money than I do if I lose it myself. May be that is a pretty strong statement, but I *hope* it is true. Sometimes when I am vexed or provoked I am tempted to say, "It teaches them a good lesson;" or, "Perhaps it will help them to remember next time." But I always feel bad to see anybody lose his hard-earned money. I know what it is, dear friends, to work hard; and I am willing to work hard, but I do want a proper compensation for my labor. When I work hard and get nothing for it, it vexes me; and when anybody else works hard and gets nothing for it, it vexes me just as much, I am sure. And when somebody is so bad and wicked that he will, *without scruple*, take another's hard earnings without recompense, I am tempted to get into a fighting mood. At such times I might make haste to pull out the tares, and root out, also, good wheat. Well, in our price list we very emphatically request that noth-

ing be returned before first writing for instructions in regard to it. When you get something that does not please you, the proper thing to do is to write and say so, telling the sender the goods are *subject to his order*, and asking for directions for disposal. Now, please, friends, bear this in mind: If you decline to receive the goods, they are not *yours*; and if *not yours*, you have no business to send them *anywhere*. Just think of taking the liberty of sending goods that do not belong to you, without authority! Even an *express* agent has no right to return goods until he has instructions so to do from the owner. If he does, he is responsible for all charges. This we have settled by actual test; therefore please remember this, that, when you receive something that is not up to contract, or that, for some reason or other, you do not want, or did not order, neither you nor your express agent has any right *whatever*, nor any *authority* whatever, for sending the goods anywhere. Write to the real owner of the property in question, and ask him his pleasure in regard to it. If he does not reply, and the things still remain on your hands, you can, if you choose, make out a bill for storage and care for them. But *until* he does reply, they are *his* property intrusted to *your* care. You may leave them at the railroad depot or at the express office, if you choose, and while there the owner must pay for storage, if he does not give orders in regard to their disposal.

Some years ago some very good friends of ours—Christian people too, if I am correct—received something they did not order. Instead of waiting to hear from us they made haste to send the goods back to us by express. Now, it happened that these goods were the product of a manufacturer who agrees to make good every imperfection in regard to them; and his instructions are that every thing shall be shipped back to the factory. Our customer, without waiting to be informed of this, sent them back to us with heavy charges, when they could have been sent more cheaply to the factory where they were made. We had to pay the express charges on receipt of the goods, and then they had to be reshipped to the factory. I was provoked, and wrote him that we should have to ask him to pay the expense of his folly in expressing them to us without any instructions from us to do so. It was the old story—because of the loss of a small amount of money I pulled up the wheat with the tares. He became angry, and said that if such a letter as that was according to my ideas of Christianity, he wanted no further deal with A. I. Root, and never wanted to read GLEANINGS any more. I wrote him, explaining matters; but he was soured, and has never traded with us since (several years have passed), until I saw a small order from him during the rush of the past season. How glad I was to see the old familiar signature! Friend —, if this meets your eye, please forgive me for my hasty letter. I should have remembered that you had been for many long years a friend of ours, and a friend of GLEANINGS; and if you were hasty it was my duty to have reminded you of it in gentle terms, at least before writing harshly.

Most of you can recall instances where those who have been excellent friends for years have had trouble over some trifling matter, and, for some unaccountable reason, former friendly terms have never been renewed. I have seen people quarrel in a good-natured way as to who should be *permitted* to bear the expense of some little sum. Each one held the other in such friendly esteem that it became a privilege to pay 25 cents, or even a dollar or more, to show his friendship and good will. This state of affairs exists because the two parties have unlimited *faith* and *confidence* in each other. You, perhaps, have friends whom you feel so sure are the very *soul* of honor that you would entrust them with almost any amount, without even a thought of anxiety. You have *faith* in such a one. This kind of faith is beautiful to behold, and I am sure it would be better if there were more of it. When the two are brothers in *Christ Jesus*, such confidence and perfect trust are still more beautiful to behold. It is one of the things in life worth living for. Well, now, such a faith and such a trust may be upset and demolished, and ruthlessly torn to shreds by just this thing I have been talking about to-day. Even such people as the ones I have described, who are the soul of honor, are still human, and have their imperfections. As a faithful friend it is your duty, no doubt, to labor with them in regard to their faults and failings, and they will think all the more of you for it, providing you do it with a careful and loving hand. I remember one such friend now; and the very thing that makes him exceedingly near and dear is because he talks to me *plainly*. He says to me things that I would hardly dare to say to anybody else, and that perhaps nobody else would be plain enough to say to me. But he says them with such exceeding kindness that I never feel vexed toward him. Now, suppose he should some time, when vexed, or sorely tried with me (or perhaps with somebody else), forget himself so far as to speak to me in anger. Even if he did, I hope and pray that God would give me grace to remember the years when he has given me only sympathy and kindness and gentleness. It wants a Christian spirit on both sides. We ought to be ready and willing to *bear* with our friends, even if they do forget themselves; and they on their part ought to be very careful about *forgetting*. Every Christian should be prepared to do *more* than his part both ways. He should do *more* than his share of forbearing, and he should do *more* than his share in forgiving. In this way these misunderstandings, and words that hurt and sting for years afterward, may be avoided. In this same line let us be *slow* to think evil. I told the friend who expressed the goods back to me that we should have to ask him to pay the expense of what he had done without orders. Under other circumstances I would have paid the amount twice over rather than appear ungentlemanly to one whom I had known so long, or rather than to appear *small* in deal. A dear friend of mine, who is not a Christian man, once saw a storekeeper and customer using hard words ove

a matter of 25 cents. He commenced to reprove them, when each party began to tell his story. He interrupted them something like this:

"But, my friend, the amount in question is only 25 cents."

One of the two asked him if he would be willing to be *beat* out of 25 cents. He replied, "Why, I would lose 25 cents *any time* rather than to use hard words, and talk to each other as you have been talking."

They were both silenced, and hung their heads in shame. The two who were quarreling were Christians. The man who said he would give 25 cents any time rather than have a "wrangle," was not a Christian. I often think of his words, and they have done me good. Let us look out for our rights, and in a good-natured way defend ourselves, even in small matters. But, dear brethren, do we not often make a great ado over something comparatively small and unimportant? Sometimes I get hold of letters written by the clerks, where the circumstances are aggravating. Sometimes I say, "Look here, my friend, all you say is no doubt true; but will it not be a great deal better to cross out this sentence, and that, and that? The letter will be just as well without it, and I know by experience that it will save hard feelings. Let us *never* stir somebody up needlessly. Let us not say severe things, even though they may be true, unless we are certain that some good is going to come from them. If it will be the means of leading this poor friend to *Christ Jesus*, by all means *let it go*; if not, strike out these passages, and have the letter written over again." Remember the wheat that may be rooted up and destroyed when we undertake with ruthless hand, and without due thought and proper care, to pluck out the tares.

EDITORIAL.

He that is soon angry dealeth foolishly; and a man of wicked devices is hated.—Prov. 14: 17.

S. W. MORRISON IN COLORADO.

FRIEND MORRISON desires us to state that he is now located in Colorado Springs, whither he has removed on account of his wife's health. He also says he is out of the queen-rearing business.

GARDENING FOR AUGUST.

If you have good ground, well enriched, worked up fine, there are several crops that may be put in now with profit. Eclipse beets; celery, if you have good strong plants; Grand Rapids lettuce, but the plants would be better than the seeds if you can get them; Egyptian onions; Early Frame and Chinese Rose Winter radish; and purple-top turnip. The latter may be somewhat doubtful; but with plenty of rain they will doubtless make a nice size for table use. Last, but by no means least, winter spinach. Last fall we sold bushels and bushels of spinach at from 5 to 10 cts. per lb., and didn't have enough. Few if any one in our community had used spinach until we introduced it, and now it is quite a staple article. It will probably take a full acre to supply our demand during the coming fall,

winter, and spring. If sown now it will get to be large and stocky, well prepared to stand the winter; yet there will be no danger of its starting to seed until in the spring. And, by the way, spinach is an excellent feed for poultry. They will feed on it all winter, as you may find to your sorrow, if you don't have your patch far enough away from their range. We can furnish the best American Savoy or Bloomsdale seed at 5 cts. per oz., or 30 cts. per lb.; 5 lbs. or more, 25 cts. per lb. It needs about 10 lbs. per acre. We sow it with a common wheat-drill, using phosphate, just as we do for wheat. Southern Prize turnip may be sown this month or next.

THE STRAWBERRY-PLANTS WE SELL, AND THE WAY WE RAISE THEM.

THE demand for the four kinds of strawberries we offer has been beyond any thing heretofore known; but so far each order has been filled by return mail. Perhaps you would like to know how we raise the plants. The original plants were set out just about a year ago. This season, just before the runners began to set, the ground was harrowed between the rows until very fine. Just at this time our large compost-heap had to be removed on account of our new building. In order to avoid handling the stuff twice, I told the boys we would put it all between the strawberries. Then we harrowed the ground again to work in the manure. After that, about two inches of ashes were spread over the surface, and this was again thoroughly raked into the soil. Then the boys went to work and spread the runners out so as to cover the ground, putting a lump of dirt (or manure if they could get hold of it) on every runner. As soon as they were rooted sufficiently to fill orders, we went through, took all that were rooted enough, pulled the others up, and swung them around in order that we might give the ground *another* tremendous harrowing. Then the boys went through again, placing the runners that had been pulled up, as before. It was a great amount of work; but had we not done it we should never have been able to meet the tremendous demand our friends are making on us for plants. The Gandies and Haverlands seemed to catch hold of the idea at the same time their roots caught hold of the manure and ashes; and, oh my! how they have just put in the time and made roots and runners! About the middle of July some of these first plants were taken up with the transplanting-tubes, and moved to a new plantation, and some of these young plants in the new plantation, in just four weeks have now four or five strong plants of their own. All the plants have been grown so far without irrigation, as sufficient harrowing has been made to take the place of it; but unless it rains very soon, the windmill will have to be called in to *help* fill orders for plants. Please remember that both Bubach and Haverland are pistillate varieties, and must have a row of Jessies, or some other staminate variety, near them.

ALFALFA HONEY.

WE make the following extract from the Lakin Index, published at Lakin, Kansas:

How doth the little busy bee improve each shining hour, and maketh honey every day from the sweet alfalfa flower! Farmer John Troutman, being the pioneer "bee-man" of Kearney County, drove into town on Saturday last, and disposed of a nice lot of that fine-haired luxury called comb honey, retailing the delicate golden sweet at 15 cents

per pound. He did not wait for customers, but his stock was eagerly taken. Our eastern friends may talk about their basswood and alsike-clover honey, but the Western Kansas man, with his fields of constantly blooming alfalfa, can exclaim, "Eureka!" and down all competitors with a marketable product of the industrious bee, made from the alfalfa bloom.

It is true, that alfalfa honey is destined to take the front rank. It has a most delicate and beautiful flavor, and all who taste it are quite willing to acknowledge that it has a little the finest flavor of any honey they ever tasted. One peculiarity of it is, it leaves no burning sensation to sensitive throats, of which some people complain.

JUDGING A QUEEN BY HER LOOKS.

WE had supposed that the day is passed when any one would undertake to decide by a queen's looks whether she produces pure bees—whether she was imported or not, etc. But, twice this season we have had customers who claimed and presumed to call a queen not what she was represented to be, simply from her looks, after an exhausting trip through the mails. One man says he showed her to all the best judges in his neighborhood, and they all pronounced her to be a hybrid. In the other case, our customer had received an imported queen, which, after a while, failed to lay. On being informed of this we at once sent him another best imported—in fact, one of the best queens we had in our apiary. Without introducing her at all, he looked at her, then carried her to a friend of his who was presumed to be a judge, and they together looked at her, and decided that she was just like the old one, because she *looked* like her; whereupon these two wise friends mailed her away to Medina again. We are glad to say that she came through all right. We do not propose to take any more risks in trying to satisfy such unreasonable people. Now, please let us have it understood, that, if you are going to judge of a queen by her looks, you had better not send to us. Our queens are to be judged by the workers they produce, and the work that these workers do. Of course, we like to have a good-sized queen; and if she is light in color, we are well aware that it goes a good way with some people. Very few queens, after a long trip through the mails, look very bright or large. When the queen is received, if there is any life in her at all, give her a chance, and do not complain until there is something to complain of.

Moral.—When anybody claims to be so wise as to be able to tell what a queen is worth, simply from her looks, set him down either as very ignorant in bee culture or very dishonest.

SPECIAL NOTICES.

COMB AND EXTRACTED HONEY FROM ARIZONA.

We have just received from the Bee-keepers' Association of Maricopa Co., Arizona, a carload of very fine extracted and comb honey. There is only about a ton of comb and about 16 tons of extracted. It is principally alfalfa, and of very fine flavor and color. The comb honey is in 24 and 48 lb. cases, with no glass, and the price is 17 cts. per lb. In lots of 5 cases or more, 16 cts. The extracted honey is all in 60-lb. cans, 2 cans in a case; the price is 10 cts. per lb. by the case of one or two cans; 3 cases or more, 9 cts. per lb. Those wanting 1000 lbs. or more will please write us for prices. From the number of inquiries for comb honey that we have, you will have to speak quick if you expect to get any of his.

We are negotiating for a carload of comb honey to arrive from Reno, Nev., between the middle and last of September. This is to come from W. K. Ball, from whom we received some alfalfa of last year's crop several months ago, which is the mildest, most palatable honey we ever tasted. The honey offered above is very much like it.

SOME STATISTICS IN REGARD TO BUSINESS AT THE HOME OF THE HONEY-BEES.

It may be of interest to many of our readers to learn something of the extent of the bee-keepers' supply business as carried on at the Home of the Honey-Bees the past year. As we have had to collect statistics for the census bureau, we give you some of the results of our investigations. We give figures in round numbers, within a very few of the actual count, and more easily remembered. The whole number of hives of the five styles we make was a little over 36,000, of which we sold 20,000 Dovetailed, 10,000 Simplicity, 3000 Portico, 1700 two-story chaff, and 1450 one-story chaff. The previous year, when the Dovetailed hive was introduced, about March, it reached a sale of 4200, and 12,000 Simplicity were sold. This shows that the Dovetailed hive has taken its place rapidly at the head of the list, and made the whole number of Simplicity diminish when every thing else has increased.

For convenience we will arrange the statistics in the form of a table, comparing a few items with the number produced a year ago, which was our largest year until the present. By this you will see the great increase, and the reason for our being (for a time) so behind on orders, and having to run day and night to fill them.

	Quantity produced and sold from Sept. 1888 to Sept. 1889.	Sept. '89, Aug. '90.
Dovetailed hives	4,200	20,000
Simplicity hives	12,000	10,000
Portico hives	2,000	3,000
Two story Chaff hives	1,100	1,700
One-story Chaff hives	900	1,450
Brood frames, Simp. size	360,000	500,000
One-piece sections	5,000,000	6,500,000
Weight of freight shipments	1,350,000 lbs	2,250,000

The number of shipments by freight or a year is about 7000, and by express 3000. The average number of hands employed for a year has been 100, and the amount paid them, \$40,000. We have turned out 20,000 Clark's smokers in a year; and 75 casks, of 600 lbs. each, of sheet zinc, has been made into queen-excluding metal, making about 80,000 sq. ft.

Of the six and a half million sections sold, we bought from other makers 1,310,000, and would have bought many more if we could have got them, rather than send out many made from dark and poorly seasoned lumber that we had to send in order to fill orders at all.

PREPARATIONS FOR THE FUTURE.

We have now well under way another two story brick building, 37x100 ft., to be used on first floor for making comb foundation and for a machine-shop, and on the upper floor for tin-shop, japanning room, and making smokers. This will give us the whole of both floors in the building 44x96, erected in 1886, for wood-working machinery. As our 90 H. P. engine is inadequate to run so much machinery we are putting on a larger cylinder to increase its power to about 150 H. P. Our Mr. Warner has been to Michigan and secured a shipload of pine lumber from which we expect to make a better quality of hives than some we had to send out the past few months. We are trying to secure sufficient basswood lumber so that we may not be caught again as we were last spring with the season before us, and not half enough dry lumber. We are beginning already to make up a stock of goods for next season's trade, and as usual we will from this date allow a

DISCOUNT FOR GOODS FOR NEXT SEASON'S USE.

The terms are just the same as they were a year ago. You can refer to back numbers of GLEANINGS, or old discount sheet; or if you write we will mail you terms. The discount will be 5 per cent up to Nov. 1, when it will drop 1 per cent each month till it has all vanished. The discount is allowed only on goods of our manufacture, bought now for next season's use, and does not apply to honey-packages, counter-goods, and the like, that you will use this fall, and which are already sold at close prices.

CONVENTION NOTICES.

The Southwestern Wisconsin Bee-keepers' Affiliated Association will meet Oct. 8, 1890, in Platteville, Wis., at the residence of E. France, to commence punctually at 10 A.M., sharp. There will be a large turnout of prominent bee-keepers of the State. A question-box, free to all, in which any subject you wish discussed can be presented and answered. Let every one be on hand and bring in his report for 1890 starting at spring count, or May 1. There will be blanks sent to each member for this purpose, in due time, by the secretary.

N. B.—The date of the above convention has been changed from the 1st to the 8th.

Boscobel, Wis. BENJ. E. RICE, Sec'y.

HOME EMPLOYMENT. — AGENTS wanted everywhere, for the HOME JOURNAL—a grand family paper at \$1 a year. Big cash premiums. Sample FREE. THOS. G. NEWMAN & SON, 246 East Madison Street, CHICAGO, ILLS.

KIND WORDS FROM OUR CUSTOMERS.

The queen and bees you sent arrived in good condition, after their long journey. In my estimation they are worth twice as much as they cost.
St. Johns, Ariz., July 3. C. P. ANDERSON.

BUCKWHEAT IN BLOOM LESS THAN 30 DAYS FROM SOWING.

The buckwheat I bought of you was sown on the 20th of June. It is now in bloom, and the bees work on it from morning until night.
Ludersville, Md., July 19. L. C. BENTON.

QUEEN RECEIVED AND SUCCESSFULLY INTRODUCED. The queen was received all right, and in very good order. I pinned her on the combs the 4th, and she stayed there until the 6th. I lost the cage, and she crawled down the combs all right; and on the 7th she had laid a dozen or so of eggs. The work was done according to the A B C.
Marvinville, Ark., July 7. G. C. LEWIS.

GLEANINGS AS AN ADVERTISING MEDIUM. I think this is the fifth or sixth time I have advertised in GLEANINGS, and I have never yet failed to get plenty of replies to my "ad." I am all sold out now—needn't insert again. I. FERRIS PATTON.
Laureneburg, Ind., Aug. 20.
[So it seems that GLEANINGS is not always a failure, after all. In looking up the advertisement we see that friend P. advertised to exchange canary birds for Italian bees or queens. Now, very likely among the readers of GLEANINGS there are more who have Italian bees to trade or swap than who wish to buy bees or queens.]

HONEY COLUMN.

CITY MARKETS.

ALBANY.—*Honey.*—White, selected, 1-lb., 18@20; 2-lb., 17@18; white, as runs, 1-lb., 16@17; 2-lb., 15@16; mixed, selected, 1-lb., 15@16; 2-lb., 14@15; mixed, as runs, 1-lb., 14@15; 2-lb., 13@14; dark, selected, 1-lb., 13@14; 2-lb., 12@13; dark as runs, 1-lb., 12@13; 2-lb., 12@12½. Aug. 25. HILBRETH BROS. & SEGELKEN,
28 & 30 West Broadway, New York.

KANSAS CITY.—*Honey.*—Receipts of honey very light at present; the demand is fair for comb. Fancy 1-lb. white-clover, 14@15c; same, 2-lb., 11@12. Dark, 1-lb. comb, 12@13; same, 2-lb., 9@11. Extracted in very little demand at present. *Beeswax*, 25@27.
Aug. 20. HAMBLIN & BEARSS,
514 Walnut St., Kansas City, Mo.

MILWAUKEE.—*Honey.*—This market now offers good encouragement to shippers of honey. The old stock of white comb is all gone, and new choice 1-lb. sections will meet with a sweet reception. Will now quote: 1-lb. white, choice, 15@16; 1-lb. white, good, 14@15; 1-lb. white, fair, 13@14; 2-lb. white, choice, 13@14. Extracted in bbls., white, choice, 7@8; in kegs and tin, choice, 8@8½; in bbls., dark, 6½@7½. *Beeswax*, 26@28, and 30.
Aug. 23. A. V. BISHOP,
Milwaukee, Wis.

BOSTON.—*Honey.*—New honey is commencing to come in, and we are selling at 18c. We are advised that the crop is short, but thought it best to start at 18c and work it up a little as the demand increases. Extracted, 7@8.
Beeswax.—Sold beeswax to-day at 30c for fancy yellow.
Aug. 15. BLAKE & RIPLEY,
Boston, Mass.

NEW YORK.—*Honey.*—Of comb honey there is neither old nor new, in this market. We have inquiries repeatedly for fancy 1-lb. new; and 14@15c could be realized probably. Common strained, Southern, 60c per gal.; extracted, 65@75. Palmetto and mangrove, well ripened, 7@7½ per lb. California, 6½@7. *Beeswax*, scarce, 29.
Aug. 21. F. G. STROHMAYER & Co.,
New York City.

ALBANY.—*Honey.*—We quote fancy white 1-lb. sections, 18; medium, 15@16; buckwheat, 12. Inferior grades and glassed sections, from 1@2c less than above price. We have received 22 half-bbls. of extracted honey which the consigner wishes held at 7c per pound.
Aug. 20. CHAS. McCULLOCH & Co.,
339 Broadway, Albany, N. Y.

CINCINNATI.—*Honey.*—Demand is good for all kinds of honey. All of last year's crop is sold, and new arrivals don't keep pace with the demand. We quote 14@16 for best comb honey, in the jobbing way, and 5@8 for extracted honey on arrival.
Beeswax.—There is a good demand, at 24@26, for good to choice yellow.
Aug. 26. CHAS. F. MUTH,
Cincinnati, Ohio.

NEW YORK.—*Honey.*—The comb-honey market is in fine condition—never saw it better, as the old honey is completely sold out. We quote the following, can sell at the following prices: Fancy white, 1-lb. paper caps, 16@18; fancy white, 1-lb., glassed or unglazed, 15@17; fancy white, 2-lb., glassed, 14@15; off grade, 1-lb., 13@14; off grade, 2-lb., 11@12.
Aug. 25. THURBER, WHYLAND & Co.,
New York.

KANSAS CITY.—*Honey.*—Receipts of comb honey light; demand good at 14@15 for 1-lb. white; no 2-lb. comb or dark comb in the market. Very little demand for extracted at present. We quote white, 6½@7; dark, 5@6. *Beeswax*, none in the market.
Aug. 21. CLEMONS, MASON & Co.,
Kansas City, Mo.

CLEVELAND.—*Honey.*—Very little honey coming into the market now. White-clover and basswood honey in 1-lb. sections sells readily at 15@16c.
Aug. 19. A. C. KENDEL,
Cleveland, Ohio.

ST. LOUIS.—*Honey.*—We have sold thus far of this season's crop about 18 tons, and find trade excellent. We quote: Extracted, in barrels, 5½@6; cans, 7½@8. White clover, comb, 1-lb., 13½@14½; inferior, 11@12. *Beeswax*, prime, 27½.
Aug. 20. D. G. TUTT GRO. CO.,
St. Louis, Mo.

DETROIT.—*Honey.*—New comb honey is selling at 14@15c; very little in market. Extracted, 7@8c. *Beeswax*, 26c for prime.
Bell Branch, Mich., Aug. 21. M. H. HUNT.

FOR SALE.—50,000 lbs. of extra fine sage honey in 60-lb. tin cans.
MERCER & SONS,
Ventura, Ventura Co., Cal.

FOR SALE.—400 or 500 lbs. of white-clover honey, put up in 12-lb. shipping-boxes, glass on two sides, for \$1.75 each. Three 5-gal. tin cans, two in box, of extracted white-clover honey, holding 5 gals., which I offer for \$5.00 each, put on board cars.
R. GAINES ROBERTSON,
Box 774, Marshall, Saline Co., Mo.

FOR SALE.—Fine white-clover and blue-thistle comb honey, 4¼x1½ sections, with separators; full weight, and fine goods. I can pack in crates of 120 lbs. each, so as to go safe by freight. I want 1½c for it here. H. W. BASS, Front Royal, Warren Co., Va.

FOR SALE.—About 500 boxes of white-clover honey, in 1-lb. boxes; price 13c on board cars.
L. D. WORTH, Reading Center, Schuy. Co., N. Y.

FOR SALE.—2000 lbs. well-ripened extracted honey.
W. H. S. GROUT, Kennedy, Chaut. Co., N. Y.

FOR SALE.—1000 lbs. of choice extracted honey.
F. W. MOATS, Brunersburg, Ohio.

FOR SALE.—Alfalfa honey, comb and extracted, quantities to suit. Address CHAS. ADAMS,
Greely, Ohio.

FOR SALE.—2000 lbs. extracted clover honey in 10-gal on ash kegs; 120 lbs. net, at 10 cents. 2000 lbs. comb honey in 1-lb. sections.
M. ISBELL,
Norwich, Chenango Co., N. Y.

FOR SALE.—Forty-five 24-lb. cases of white honey, first quality, at 15c per lb. cash, on board cars.
C. & F. OLMSTEAD, East Bloomfield, Ont. Co., N. Y.

WANTED.—One or two thousand pounds of nice comb honey. Write, giving amount on hand and price wanted.
A. D. ELLINGWOOD,
Berlin Falls, N. H.

WANTED.—White comb and extracted honey; state price, package, etc.
B. WALKER, 177d5
Capac, Mich., or Prairie du Chien, Wis.

ARE YOU GOING

—TO ATTEND THE—

MICHIGAN STATE FAIR?

If so, please call at "Bees & Honey Hall," and examine the "Golden Italian Bees," on exhibition by JACOB T. TIMPE, of Grand Ledge, Mich. For prices on Queens see Oct. 1st. GLEANINGS. Don't forget to call while at the FAIR. I shall also have other races on exhibition. Do not fail to see them.

Vol. XVIII.

SEPT. 1, 1890.

No. 17.

TERMS: \$1.00 PER ANNUM IN ADVANCE; 2 Copies for \$1.90; 3 for \$2.75; 5 for \$4.00; 10 or more, 75 cts. each. Single number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY

A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canada. To all other countries of the Universal Postal Union, 18 cts. per year extra. To all countries not of the U. P. U. 42 cts. per year extra.

SELLING SECRETS, ETC.

DR. C. C. MILLER GIVES US SOME FACTS FROM THE STANDPOINT OF A PHYSICIAN.

Friend Root:—It is so many years since I had any thing to do with the practice of medicine that I hardly count myself one of the medical profession; but I think I can help you a little to understand why little or nothing is said by them about what you evidently consider a fit subject for ventilation—the Dr. A. Wilford Hall matter. In the first place, his case does not stand out as prominently to their minds as it does to yours. It is only one of a hundred. Indeed, in some respects it is of a better type than common; for at a guess I should say that in many cases the man who pays \$4 for the secret gets the worth of his money, or at least is not harmed by it. I have just now picked up the first religious paper that comes to my hand—and it is one of the best of its class—and looking at its advertising columns I find a medicine offered as a sure cure for consumption. I very much doubt whether any one ever was or ever will be cured of consumption by this medicine; and I suspect that it may do harm in a great many cases, where the Hall treatment will not. These things are common. You see them every day, and every day the people are paying out a good many four dollars for things worse than the Hall business. If a physician should try to expose every thing of this kind he would have his hands full; and, moreover, people would say he had an ax to grind in so doing. Good honest people are found in plenty who believe in such things, and resent any word said against them. A somewhat similar case came within my knowledge in the sphere of bee-keeping. A certain party had been doing a business of some extent, selling at \$20 a colony of bees not worth half that, and other things as bad or worse. I felt that something ought to be done to prevent people being defrauded, and I wrote some very plain words about it for an influential publica-

tion. Would you believe that the good editor, with misdirected charity, squelched the thing, saying that he thought the party was doing better—a kind of “better” that every thief uses who changes his tactics whenever it makes him safer from detection? Perhaps Dr. Hall will do better—take \$3 instead of \$4 whenever he thinks he can make more by so doing.

But there is another reason why physicians don't say any thing against Dr. Hall; and that is, they don't know any thing about his treatment. Every one who gets the secret agrees to keep it; and, however strongly I may think Dr. Hall a humbug, if I don't know positively what his treatment is I am not wise to say any thing about it. I received from him an offer of the secret, practically free, on condition of my keeping it secret, and I suppose it is his tactics to offer it in the same way to all physicians. This helps to keep their mouths shut, and some among them will act as “agents,” thus increasing his receipts.

I admire your pluck, friend Root, in attacking error; and whilst there will always be those who are anxious to be humbugged, I suspect your words may be the means of saving to some their four dollars. C. C. MILLER.

Marengo, Ill., Aug. 16.

Friend M., very likely you are right. This makes the matter sadder still. Is it indeed true, that the people of our nation—those who are out of health, and possibly those who are at the same time overworked—are continually investing vast sums of money for something that does no good whatever, and oftentimes, as you state it, a positive harm? Why can't our experiment stations furnish some facts for the people out of health, just as they have furnished facts to the farmer who has been in the habit of paying over his hard earnings to quacks and swindlers? It seems that this matter of medi-

A GLIMPSE OF FLORIDA IN JULY.

AN APIARY UNDER THE GRAPEVINES AND PALMETTOES.

cine and medical treatment to the human family is as important as that of protecting our domestic animals from the errors of quackery. As an illustration of current superstition, I want to mention the following: A few days ago a very good and intelligent farmer, who is at present taking care of our cow, came to my wife for some salt and pepper. Then he wanted some turpentine. He said the cow had got the "wolf-tail," or something that sounded like it, and that the only thing to do was to split the end of her tail and put in some salt and pepper. Then some turpentine must be rubbed between her horns, and she would be all right. And poor bossy had to submit. When I heard of it I began to remonstrate. The man who drives the market-wagon, and who, by the way, has for many years *taught school* in winter, joined in, and declared that splitting the cow's tail was "orthodox" and right. He said he had a cow in that same fix, and a good farmer told what the trouble was as soon as he saw her, and the treatment cured her *right straight*. Now, the probability is that the poor cow had been overfed, and that is why she could not eat her supper. If simply let alone, she would have come out all right. The question that occurs to my mind in such matters is this: Who in the world had the wonderful *acuteness to discover* this remedy? Through what process of study, invention, and *reasoning*, did *any* human being arrive at the *astounding fact* that *salt* and *pepper* (nothing else will answer, mind you, and one alone would not answer—you must have both), are needed? Furthermore, the application must be made to the *end* of the cow's *tail* after it is split open. Then turpentine (nothing else *here* would answer, mind you) must be applied between her horns. In the present case, of course no money was wasted; but if it is really true that the laboring classes of our land are continually paying out a large part of their earnings in a blind and senseless way, and for that which does little or no good, is it not a sad thing to contemplate? By the way, Dr. Hall has occupied a large space in his periodical for August, to call myself and Dr. Kellogg names. He has, however, paid me so great a compliment in putting me side by side with so celebrated a physician and author as Dr. Kellogg, I feel well enough pleased to let the matter drop where it is. Yes, it is probable that GLEANINGS has saved whole neighborhoods from investing their money. I hear of it continually from agents who have, like Othello, found their "occupation gone" because somebody got hold of a copy of GLEANINGS, and carried it around, before the agent got in his fingers the four dollars from each family. Now, please do not gather from the above that I do not approve of Dr. Hall's treatment. I feel sure it has done and will do much good; but it is not his invention, and he has no legal nor moral right to receive money for something that does not belong to him.

Friend Root:—I send you by this mail a photograph of a corner in my bee-yard, taken from a window in my bee-house. My object in taking the picture was to give Prof. Cook a photo of the cabbage palmetto in full bloom, but I haven't done it. This picture was taken last Thursday, July 17, to test my plates, preparatory to taking some palmettoes when they come out in full flower, as I expected them to do in three or four days; but as the buds began to blight and drop immediately, from the effects of a severe drouth we have been having, I made this negative answer rather than to score an entire failure. The trees in this picture would have shown double their present bloom if they could have perfected the buds. I cut a sprig of bloom from a neighboring tree, however, and, setting it on the ground beside me, held its top over my head. This will give you an idea as to its size and form.

To my left you see a section of one of my beehives, covered by succupernong grapevines. This family of grapes needs but little pruning, and grows enormously; and bears by the hundred bushels in some cases. You will notice that they are going over the palmetto-trees, shutting off the view beyond. They make almost a perfect shade for bees; and the Thomas variety is one of the sweetest grapes known. Having a rather thick skin, and growing in bunches of 4 to 12 berries only, they can never compete with the Delaware and other fine bunch grapes for table use, though many prefer the Thomas to eat out of hand. The berries are very large, often measuring $3\frac{1}{4}$ inches in circumference, on thrifty vines, and no insects or diseases trouble them, though the mocking-birds are very fond of the Flowers variety, which is enough smaller so that they can handle it.

This year, for bees, has been an abnormal one. The spring flow was very light on account of dry weather and the burning of the woods. Not a normal swarm was reported during the usual swarming season from February to the middle of May, and considerable feeding had to be done in April to prevent loss of colonies. I had many colonies that had plenty of honey in the hives to carry them through, but I fed all, as is my custom, in April, to prepare the bees for the summer flow. Probably my bees were in better shape than almost any others here when the flow commenced. I started the season with 93 colonies; worked 92 for extracted honey, and have taken 15,000 lbs. to date. I shall probably make it 8 tons by the time I get through this round of extracting. I have had 22 swarms right in the mangrove-honey flow (very unusual), and have had my bees draw out 400 frames of foundation during the past four weeks.

Friend Poppleton caught 25 colonies of black bees from the pine woods, where they had a little better spring forage, just at the beginning of the mangrove bloom, and he has taken ten barrels of 400 lbs. each from them. I think he had one swarm which absconded. The rest of the bee-keepers have been quite successful about here, and are feeling in good spirits. The quality of the honey is even finer than usual this season, as there was very little besides the mangrove crop gathered, and the weather has been very dry throughout the whole flow. My own crop has gone through my evaporator as usual, and is A No. 1 in quality.

Having never made a report of my crops for 1888 and '89, I will here state that, in 1888, with about 100 stands I took 5500 lbs.; and in 1889, with 96, spring count, 4500 lbs. Both years were

W. S. HART'S APIARY, HAWKS PARK, FLORIDA.

considered very poor, and my average was as high as was made, I believe, while some bought honey of me to feed in the fall, having failed to get enough to carry the bees through.

Hawks Park, Fla., July 22. W. S. HART.

Friend H., we are exceedingly obliged to you for the magnificent picture you have given us. We congratulate our artists on having copied the photograph so well. The palmettoes have always been a class of vegetation wonderfully attractive to me, both in my trip to New Orleans and the late one to California; and I assure our readers that no picture can exaggerate the beauty of vigorously growing specimens of many of the varieties. Friend H., we are very glad to know that you have made so good a report during this season, while so many have given us such discouraging accounts. If your hives are not Simplicity, I should judge they come pretty near it, from their looks in the picture. What a pleasant place that must be to work! I suppose the ground under the trees and around the hives is sandy and clean, as it usually is in the home of the palmetto.

A GLASS PAPER-WEIGHT SHOWING THE MATHEMATICS OF THE HONEY-COMB.

A TRUE DODECAHEDRON.

We have finally succeeded in getting a thousand glass paper-weights, such as are described in our heading. Before we could get them, the order had to be sent to Germany to have them made, and it has taken a little over a year and a half to get them out. The adjoining cut, taken from the A B C book, shows what they are like.

A TRUE DODECAHEDRON.

This beautiful figure has exactly 12 sides; 6 of the 12 sides are exactly on the angle of the cell of the honey-comb; and the 12 lozenge-shaped sides are exactly the shape of the figure the bees make in building perfect cells. The paper-weight is a little less than $1\frac{1}{4}$ inches through its longest diameter. It is made of beautiful crystalline glass, and is ground so that it sparkles like a huge diamond. They are the prettiest objects that can be found to grace a writing-table, or even a center-table or ornamental bracket. The usual price is 50 cts. each. By having them made to order in thousand lots, we are enabled to sell them for 20 cts.; 2 for 35 cts.; or in lots of 10 or more, 15 cts. each. If wanted by mail, the postage will be 3 cts. each, or we will furnish one as a premium to everybody who sends us a subscription to GLEANINGS from some one who has never taken it before. This beautiful figure will be of interest to bee-keepers, as it exemplifies and illustrates so clearly the problem the honey-bee solved in making this lozenge-shaped figure with its angles so mathematically exact. In

giving lectures, or even in giving a talk on this wonderful problem, this little figure illustrates the subject most beautifully. See the A B C book for full particulars.

ANOTHER REVERSIBLE EXTRACTOR.

THE REVERSING DONE AUTOMATICALLY WHEN UNDER FULL MOTION.

There is a demand among bee-keepers who run business on a large scale, for a high-grade extractor that will extract the combs on both sides without stopping to reverse the baskets. Some attempts have been made to get up such an extractor in this country, but so far they have not been a success, because they tried to reverse the baskets *against* centrifugal force. I send drawings of the inside gear of a new extractor which reverses the combs by *centrifugal force while going at full speed*.

MCINTYRE'S PROPOSED REVERSIBLE EXTRACTOR.

Fig. 1 shows the extractor ready to receive the combs full of honey. When the baskets are full you take hold of the little crank on the axle of the basket and turn it half way round, when the baskets will appear as in Fig. 2. Turning one basket turns all at the same time. A pin drops into a slot in the hub of the center-wheel, which holds all the baskets from turning out again until the first side is extracted. When ready to reverse, this pin is drawn out of the slot by means of a little rod running up in a groove in the center-axle, and terminating in a knob above the gearing. The combs, being heaviest next the top-bar, will cause the baskets to start, when they will all fly out as in Fig. 1, and extract the other side. It will not be hard to stop when all the honey is out of the combs; but a brake can be put on if thought necessary. It will have to be geared, because the radius distance is much less than in the old-style reversible, even when the baskets are out, as in Fig. 1. It will require a can about the same size as the Stanley extractor. The large wheel in the center is 11 inches in diameter, and the wheels on the axles of the baskets are 4 inches in diameter. The baskets should be $1\frac{1}{4} \times 10 \times 1\frac{1}{2}$ inside for the L. frame.

The readers of GLEANINGS will understand that this extractor has never been manufactured. The figures are drawn from imagination; scale, $\frac{1}{16}$ for the L. frame. I am not in the supply business, and never expect to be. If any one should manufacture them, and find them a good thing, a complimentary extractor will pay the inventor for the idea. J. F. MCINTYRE.

Fillmore, Cal., July 1.

The idea, friend M., is quite ingenious. Of course, it remains to be seen whether it will work as well in practice as it does on paper. Yes, there is a demand for an extractor for large honey-producers.

AN INTERESTING LETTER FROM THE OLD WORLD.

TEMPER OF THE EGYPTIAN AND OTHER ORIENTAL BEES.

Mr. Root.—In GLEANINGS for May 15, you say you are surprised that I say nothing about the vindictiveness of the Egyptian bee. I think most bee-keepers will agree with me in what I am going to say. In the first place, the bees I saw in Egypt, and some in very considerable apiaries, were very quiet, not to say docile, though we did not handle them; all we did was to walk in front of the hives and look in at a hive. They showed no more disposition to sting than our Palestines. I fully agree that our Oriental bees—Cyprians, Syrians, Palestines, and Egyptians, are more difficult to handle, especially for the beginner, but they *can* be handled after all; and when we remember it is not more than ten years since these races have been imported largely (except the Egyptians) there has hardly been time enough to weed out the most vindictive, and strike just the good qualities required—docile, prolific, large, yellow-tailed. Mr. F. Benton and myself laughed one day at a man desiring all such qualities. It is rare to find all these combined. I know some one will say, "Why did you not do it?" Because, in the first place, Benton was the only man I know of who worked to any extent in the raising of Oriental queens; and although he may have weeded out the worst, he never stayed long enough in one place to find out all the desired qualities; and then, again, a nucleus may be handled without smoke and veil; but as soon as this same nucleus has grown to be a full-sized colony, things take another turn, and the bees seem very angry and almost impossible to handle, if all necessary precautions are not taken. A full-sized colony is never to be handled without smoke, though you can a nucleus. A few puffs from the smoker will perfectly subdue the same colony at one season of the year; while in another, a good Bingham is necessary to blow almost continually while manipulating.

It is only four months since I saw the first Bingham smoker, which I received from the Home of the Honey-bees; and it is only half the work to subdue our bees during the orange-blossom honey-flow, when with us the bees are wildest. We could not work them at all without veils while extracting, and it was very difficult to do so even then without gloves during the orange-blossom season; but we do it, and extract orange honey and feel well protected all the while.

MOVING BEES WITH CAMELS.

In May and June we moved our apiaries to the land of the Philistines, in the tribe of Dan. Owing to the scarcity of thyme in one place, I divided my apiary, consisting of 100 hives, into three. They are about $1\frac{1}{2}$ miles apart, very near the village of Ekron. You know the camels kneel down, and the hives are put on their backs without a stir from the camel, and then the clay hives, or those made of mud, as in Egypt, are exceedingly strong, and would bear any thing. The only danger is the bees getting out. We also move all our bees on camelback, and I suppose we have just as much or even more trouble than you have with horses and wagons. When it is time to move we put a spacing rack in the bottom of the hive, and two in the center, made so as to hold the frames below as well as the frames of the super. There are 13 frames in each hive and in each super. Then the super is put on and fixed on both sides by clasps, the clasp being screwed on the super, and a hold for the clasp is screwed on the hive.

A quilt is now put on, and the cover screwed on. The hive has ventilating holes covered inside by wire screen. In years gone by we moved to the mountains, and it generally took us two or sometimes three nights to arrive at our destination. Only two nights the camels had to go faster, and we traveled an hour or so by daylight, which plan we left altogether, on account of some terrible adventures we had to undergo.

One evening in the last decade of June, on Thursday, we started from Jaffa with 13 camel loads of bees (104 hives). The hives were all supposed to be well arranged; and with a good supply of all necessary implements we followed on horse and on donkey. We lost a good deal of time loading. The night was far advanced; and with the slow movements of the camels, morning came before we had got far enough, so we decided to continue by daylight. I shudder when I think of it. Somehow or other one hive got loose, and every one had to flee for his life. The camels got wild; some threw off their loads; the hives were tumbling about; my friend and myself were running about with open knives, cutting ropes, and helping the poor animals away. When all the animals were galloping away in the distance, together with their drivers, we had to look out to ourselves and hives. We were stunned with stings, being unprotected. Our veils, gloves, smokers, etc., availed us very little, for not only had all the hives to be lifted up from the ground, but a good many were cracked, and bees were furiously streaming out; but we had also to open the hives; for in the boiling sun, surely they would have been suffocated by night. It was not before four o'clock in the afternoon when the bees had forgotten about the terrible events of the morning, and we had rested, and again neared the hives with "fear and trembling." We repaired all the damages, and started again to loading camels, the stung camels being very fidgety. After a good deal of tying, screaming, howling, and what noises imagination alone can conceive, we again drove fast in the direction of Jerusalem. We arrived in this town at daybreak; but we had to go beyond Bethlehem, four miles distant. We decided to go, not having had enough of our lesson the day before. It was Whitsunday morning, and we had hoped to arrive early enough to take our rest. We hurried on. The camels were walking behind each other, when we had just passed the convent of Elijah the Prophet, a place held in great veneration by Christians and Moslems. In the rock is the place where the great prophet slept when he fled from Ahab, king of Israel; for from the holiness of his body tradition made him sink into the rock, as though it would have been a bed of down. No Christian passes but makes the sign of the cross, and stoops down to kiss the hallowed place. The road is now closed in by high stone walls, to prevent animals or people getting into the olive-yards belonging to the convent. The last of the camels got frightened and leaped toward its fore-camel, and a hive got loose. The bees streamed out furiously, and attacked the camel, then the one before it; but the other eleven could flee together with their burdens. I slipped on a veil, handed the donkey to my brother, and with open knife I ran for the camels' lives. The ropes tying the hives were cut; they fell off, and only 16 hives were now thrown on the ground. My brother put the animals hardly 200 paces away, and came running to help me. The camel got countless stings and galloped off. When we had set up the hives we just climbed the walls, jumped into the olive-yards; and, folding all our clothes faster, we had to remove the bees from the main road. The Christian

inhabitants of Bethlehem and Betjala were going in numbers to Jerusalem, while French pilgrims were on their way to Bethlehem. Our animals now got loose and galloped toward the bees. The horse galloped past; but Grey, finding the upright hives a good opportunity to rub off the bees, roused the interior bees more and more. I jumped back and tried with all my might to send him away. Beating and pushing availed nothing. He was now literally covered with bees; and although only five minutes had elapsed, he could hardly move on. We now got him far enough to put him near the stung camels, and had now to carry the hives over the walls to clear the road. They weigh between 70 and 80 lbs. per hive. We managed to clear the road, but the bees were still more furious; and with veil and thick leathern gloves on we stopped the passers-by, one at either end of the lane. Some protested, some asked why, and many, in fact, were frightened by our strange looks. The most of them could not understand the trouble. We had to call out in all languages at the top of our voices, "Bees! danger! destruction! get away!" and gesticulating meanwhile to indicate what we meant. They had to turn round the olive-yard, taking considerably more time. One Turk could not understand the trouble; and although I could find a few Turkish words, he insisted on its being the Sultan's road, and I had no right to interfere. But the bees interfered with him, and he understood that language better, for he turned round and fled.

It was late in the afternoon. The bees had quieted down so that we allowed first one and then all to pass. I was expecting some government notice, but it passed unnoticed. We arrived at our destination. The donkey died two hours after he got stung. The first camel died a fortnight after. I could not bear to hear anybody shouting, and for many weeks I started up from sleep by imaginary sounds, as knives, camels, bees, and such implements as we had to protect ourselves. It was very ruinous, those dreadful adventures. It decimated the bees, unnerved us, and several animals were killed. Happily we found good pasture in this vicinity, and it is here I now move to every year. It takes the camels only one night. At daybreak they put down their loads; the hives are put in rows, and the bees not yet roused, so the hives are opened, and all goes on peacefully, of course. In the evening, while loading, the bees now and then got out by some crack, or badly fitting super. It was then quickly unloaded and rearranged. Stinging is, of course, a secondary matter, for both man and beast get their share; but these disagreements will have to be overcome as long as we have hives and supers; and there comes in a question. I hope some of our bee-keepers will tell us their opinion: Will a hive give the same amount of honey if the 26 combs are on a level instead of being on halves above each other? or if a frame is made bigger, so as to give 15 frames the same amount of square inches in comb.

PH. J. BALDENSPERGER.

Jaffa, Syria, July 24.

Friend B., I believe you have had more experience, or at least more disastrous experience, in moving bees, than any one else among us. If any reader of GLEANINGS has ever had any thing to match this, let him stand up and speak. Having a row with bees and horses in your own country, where you can use your own language, is surely bad enough; but among a traveling people, who speak all languages, who can imagine your worry and trouble? I think,

if I had been you, I should have declared, with considerable vehemence, that I never wanted to transport bees any more. I can not help pitying the poor camels. I suppose you do not have any humane society around there to arrest you for cruelty. By the way, how much is a camel worth, say compared with our horses? Friend B., I know exactly how you were unstrung about the time you dreamed of the *melee* as soon as you went to sleep. Our new east and west railroad has just been invading my market-garden grounds. They go entirely through it the longest way; and the cut they make is from 6 to 12 feet deep. I made friends with the bosses at the outset; but the teamsters, a great part of them, are a reckless, blasphemous lot. I tried a little to stem their torrents of profanity; but when the boss got mad and swore too, it was pretty up-hill work. Finally when a dozen teams with drivers and helpers invaded our grounds, and threatened to spread their poor clay soil from the deep cut all over my enriched land, I fought for my property and my gardens. Of course, I had plenty of helpers, and our own teams kept just before them moving the rich surface soil out of their way. But when night came I was not only thoroughly tired, but I caught cold by being out in the rain without any coat. I woke up in the middle of the night, with a headache; and as soon as I tried to sleep, the curses of the teamsters, the rattling of the scrapers, and the general clamor, followed me in my dreams until there seemed no peace, either awake or asleep. I opened my eyes wide and tried to consider the matter with reason; and when that did not stop the noises I tried to drown them in sleep. Then I began to think how thankful I should be if I were once again just free from that racking pain in my head. And I began wondering if I had not forgotten, in the many long years, of the blessing of *health*, and the ability to sleep *sound* every night. I did finally thank God then and there, and in a little time peace stole over my troubled senses. In the morning I awoke, refreshed and free from pain, and nothing remained but the memory of a couple of hours' misery in the middle of the night. Your mention of starting in your sleep reminded me of it.

AN A B C SCHOLAR'S EXPERIENCE.

A LADY WHO HAS HAD SUCCESS WITH BEES.

I sent to you for two Simplicity hives about two years ago. I have had six more made, and now have them filled with bees. I had three swarms last month. There is little or no white clover here, but lots of willow, plum, grapes, and basswood, in the ravines close by. Then the prairies are full of different varieties of goldenrod, besides the immense plots of corn and pumpkin blossoms grown by the farmers; also the buckwheat. There are only two people besides myself who keep bees here. One is a farmer about two miles out. He has only box hives, and his bees swarm a great deal, but he

gets no surplus. He turns a small box over the hives for the surplus, and has a small hole through the top of the hive for the bees to pass to it, but the temperature there is so low that the bees do not even go into it to rest. He had three large swarms come out nearly all at once, and they all clustered together. After hanging about half an hour they took French leave, and went into a hollow scrub oak in the ravine near his house. He told my husband, about two weeks after they had swarmed, that he might have them for \$1.00, as he did not know how to get them out. So we went at once, and my husband cut down the tree and split open the trunk, which was about a foot in diameter, and ten feet long, and all hollow. They had about 15 lbs. of lovely honey. I took out some of the comb, and all the brood; and having a Simplicity hive at hand we fastened all in, took it home, put a 30-lb. surplus box on top (without any bottom to it), putting starters of foundation in top, and in about three weeks it was filled with white basswood honey. I took it off and put another on, which they again filled. So you see our dollar was well invested.

I winter my bees in the basement of our barn. We had one end partitioned off for them, where it is dark and quiet. The temperature is apparently about right for them. I put chaff cushions on top. I sold a colony this spring for just what I paid for them—\$6.00.

Clark's smoker works all right, but I seldom use smoke in opening hives at this time of the honey season, for the bees pay no attention to me. It does not take to exceed ten minutes to move the frames from one hive to another, for I keep my hives perpendicular, and the combs very seldom require any attention in straightening.

I do think that bee culture is a delightful occupation for any one. It is not too laborious for a lady; besides it is such a pleasing study, and the returns are very large in comparison to the outlay.

I began with two colonies two years ago. They were in old boxes when I got them, so I just let them swarm (got 3 swarms), and sold the old colonies for what I gave for them. So you see I am considerably ahead.

Mrs. A. C. MONAGHAN.

Gary, South Dakota, July 1.

CLEANSING FOUL-BROODY HIVES, ETC.

FRIEND DOOLITTLE TELLS HIS OPINION AND EXPERIENCE.

A correspondent writes: "I have had foul brood in my apiary, and, as far as I know, I have eradicated it by the plan given by the late M. Quinby, which is similar to that recommended by D. A. Jones, of Canada. The bees were all placed in new hives, and now I want to know what to do with the old ones, so that I can use them again another year, for I do not feel able to lose them."

In replying, I beg leave to answer this question through GLEANINGS, as such answer may be of use to some of the readers besides the correspondent. The plan I used on the most of my hives, when I had foul brood during the seventies, was to scald the hive by plunging it all over in boiling water, in a large kettle which was used on the farm for cooking food for the hogs, heating water for butchering, etc. The hives were put in first and scalded, and afterward the frames of combs, thus scalding the frames and making the combs into wax at the same time; for as I made all of my frames by hand then, I thought I must save them. However, in these days of machinery I do not think

that it would pay to bother with the frames, for this scalding process makes them untrue and in poor shape for use again, so that new frames are much the cheaper in the long run. Later on, a bee-keeper living several miles away called me to his apiary to see if he had foul brood. I found it in several of his hives, and told him how to treat it. After he had cured it he scalded the hives by pouring water from a boiling tea-kettle on to the inside of the infected hives, and no foul brood was the result afterward. If you are sure that the hot water hits every nook and corner of the hive, I do not know why this plan would not answer where nothing holding boiling water is at hand large enough to put the whole hive in. The first would be the safest, however. Some claim that the hives do not need scalding or doing any thing else with them, if they are allowed to stand outdoors exposed to the weather through one winter. They say they believe that the freezing and thawing of one winter is amply sufficient to destroy all the spores or germs of foul brood about any hive. I should be inclined to go slow on this, trying only one or two till I had proved for myself that there was no danger from such hives.

While I am on this subject of foul brood I wish to especially emphasize what has been lately said in our bee-papers against sending samples of supposed foul brood to different bee-keepers for their judgment in the matter. Only lately I received such a sample, which might have worked me untold injury, if not some one else near the postoffice. Being very busy that day I did not go for my mail till late at night; and as a friend brought out the mail for me it was placed in the buggy without much thought, save to take it home. I came near leaving the mail in the barn with the buggy, but finally thought to take it to the house. In taking it out in the dark, I felt a package in a dilapidated condition; but not wishing to strike a light it was left on the table till morning. Imagine my feelings when I found, the next morning, a package of torn and soiled paper, saturated through in places with thin honey and mashed brood, giving off a scent while being undone which told me at once what it was. I was not long in consigning it to the fire and thoroughly washing every place where it had touched. As it was a time of scarcity, if I had left it in the barn, as I came near doing, in all probability the bees would have found it before I went out to feed the horse, as I do not feed him early, feeding but twice a day. Then the postoffice window is near where the mail is distributed, where again a neighbor's bees, who lives in the village, were exposed to this same contagion. Now, friends, whoever reads this, don't do such a thing as to send foul brood in the mails as samples, for by doing so you are liable to expose your brother to the same ills which you are so anxious to be rid of yourself. The books of the present day are sufficiently explicit in describing this disease, so you should be able to tell it yourselves without a reasonable doubt, with this additional test: Whenever you find something which you think is wrong about the brood in any hive in your yard, the first thing you are to do is to close that hive as quickly as possible, so that there will be no chance for other bees to get at the honey, and go and wash your hands and all else which you have used about the hive. This examination will tell you whether the bees are strong enough to repel robbers; and if so, the entrance should be contracted so you are sure no robbing can occur. Now leave the hive entirely alone till near night some day, about ten days from that time; and after the other bees are done flying, open it and examine it closely, washing your hands, etc., as before.

If you still think there is a chance of its being foul brood, leave the hive closed again for two or three weeks, providing it has plenty of bees to resist robbers, when you are to examine it again.

Now bear in mind that genuine foul brood is *aggressive*, and never *retrograding*, so that, if you find more of it than you did at first and second, together with the symptoms the books describe, that colony should be burned up at once, and gotten out of the way, before any of the rest have a chance to carry off any of the honey. If, on the contrary, it does not perceptibly progress, or there is not as much as before, keep watch of it till you are assured there is no harm in it. In no case change combs with any other hive, or expose any of this honey till you are sure it is not foul brood. Unless at least one-fourth of the apiary had foul brood, I should not attempt to cure it save by burning all up, for I do not think it would pay any one to run the risk he would have to in trying to cure the disease for less than that number.

G. M. DOOLITTLE.

Borodino, N. Y., Aug. 18, 1890.

In Ernest's absence I should say that we heartily concur with all that has been said in the above. The principal difficulty in curing the disease is that the average bee-keeper has no comprehension of the care and nicety required to avoid spreading the contagion.

QUEEN-EXCLUDING ZINC.

ITS USE IN FINDING QUEENS AND PREVENTING SWARMS.

Since the invention of the queen-excluding board, many new and useful ideas have presented themselves, and many more will in time come into use. I conceived the other day that it might be made useful in finding the queen, and made a box the size of the hive, 1½ inches deep, with bottom, but one end out. I nailed on top a piece of zinc. We now have a box 1½ inches deep, of the size of the hive, with one end out. To use, set it in front of a hive with the open end near the entrance of the hive in which we are to find the queen; lift the combs carefully, and shake into an empty hive without top or bottom, which is placed on the excluder-box, and you will smile to see the workers slip through, and, attracted by the noise in the hive, march in; and you will smile again to see the queen examining the different holes to see which is the largest. Why, all you need to do is to shake down the bees and help yourself to the queen. Another plan works equally well; that is, to place between two hives a piece of zinc board, and shake the bees in the upper hive as before.

For non-swarmling extracting, when the hive is full of brood, and honey begins to come, place a set of empty combs or foundation below with the queen, the brood above, and the zinc board between, and they will roll in the honey if it is to be had, and will fill the upper story as the brood hatches, and the outside combs below. By extracting and changing every two or three weeks as above, we need not fear swarming, and we can rear queens above very nicely without cost. I have a number hatched out in the upper story, with their entrance in the opposite direction to the hive below. With this plan I believe we can requeen and increase or not, as we desire, and have no swarming.

Oswego, N. Y., June 13. F. H. CYRENIUS.

Both of the uses of zinc (viz., in finding queens and preventing swarms) have been before sug-

gested, but that does not alter their usefulness. With black colonies the zinc method can be used to pretty good advantage at times. In Italian or Carniolan stocks it would not pay to bother with the zinc, as the queens can usually be found on the second or third frames removed.

WALKING-STICKS, ETC.

PROF. COOK TELLS US MORE ABOUT BUGS AND INSECTS.

The insect sent by James Crafton, Canada, is the common walking-stick, *Diapheromera femorata*. At Mr. C.'s request I send a description for GLEANINGS. This insect is well named, as it looks like an animated stick, with stick-like legs attached. It never has wings. When young it is green, and rests upon the green leaves on which it feeds. When older it assumes a more sober, gray, or bark-colored hue. Now it rests on the twigs which it so strongly mimics both in form and color that it is very difficult of discovery. This specter-like insect feeds on vegetation, but is rarely common enough to do any appreciable mischief. Sometimes they are so common in forests that the falling of their eggs, which are let drop, are said to resemble, as they strike upon the leaves, the falling of raindrops. These insects, like the crickets and locusts, to which they are related, are possessed of jaws. They are entirely harmless, and may be handled with no fear of harm.

THE LUNA MOTIL.

S. C. Gordon, Georgetown, Ohio, writes: "I have no 'snaix' to send you, but I send by to-day's mail a couple of moths and some of their eggs. Please, if your busy life will permit, give history and description in GLEANINGS."

These beautiful, green, long-tailed moths are the luna moths, *Actias luna*. They are our handsomest silk-moths. The larva is a fine green caterpillar, with hairy tubercles, and oblique yellow bands. It feeds on walnut, hickory, maple, etc. Although each moth lays scores of eggs, yet so few escape their bird and insect enemies that they do no perceptible harm to our finest shade-trees. The cocoon is rounded, and much like the cocoon of our oak silk-moth. The moths are of a very delicate green hue, and each hind wing has a long tail-like projection. I think these are by all odds our finest silk-moths. It is difficult to conceive of an insect more beautiful, either in color or form.

THE COMMON CICADA, AGAIN.

Mr. M. J. Langord, Highland, Minn., and H. C. Grover, Loyd, Wis., each sends the common cicada (*C. Tibicen*), the same that I described for GLEANINGS yesterday. These cicadæ are very common this year. I took my class a few days since to Grand Ledge, a deep cut through the rocks on Grand River. We found these cicadæ very noisy and common at that place.

BUMBLE-BEES IN DISGRACE.

The black nude insects received, one from R. E. Ashcroft, Brookside, Mich., and the other from M. J. Langord, Highland, Minn., are bumble-bees that have got into the bee-hives, probably while the hives were open; and the bees, in dragging them from the hives, have pulled all the hairs out of them. I have often seen just such cases in our own apiary. Often the bees in their rage will not only strip the poor bombus of its hair, but of its legs and wings as well.

The long black handsome beetle, with paral-

tel sides and impressed punctured lines on its wing-covers, sent by J. E. Dart, Connesauga, Ga., is *Passalus Cornutus*. The last name is given because of the horn on the center of the head of the male. This beetle is common in Michigan, and extends to the Gulf. The grubs live in and feed on rotten wood. This insect is closely related to the common stag-beetle, or "pinch-bug," and has similar habits. I comply with Mr. D.'s request and answer in

GLEANINGS. A. J. Cook.
Agricultural College, Mich., Aug. 15.

RAMBLE NO. 27.

NIAGARA FALLS AND STEUBEN CO.

Our continued journey led us through Charlotte, on Lake Ontario, a famous summer resort for the Rochester and Western New York people. Our westward career was to end in Rochester; but being so near Niagara Falls, and thinking we should never again have the opportunity of seeing them, we resolved to spend a day there, and were providentially favored with a beautiful sunny day, and rambled and photoed to our heart's content, making some fine shots, with which we can revisit Niagara while cosily seated in our study. Our stroll across the bridge, with camera in hand, was interrupted on the Canada side with the question, "What is that ere camera thing you have in your hand?"

"Yes, sir," said we, "this is a camera thing. Any objections to my taking views?"

"Not the least, sir, if you are going to return soon; but if you are going on you must pay duty."

I gave him my proposed route to Horseshoe Falls, then down to the railroad Suspension Bridge, and back to the American side. He looked us critically in the face, and as much as said, "I know you are an honest man;" then audibly, "You can pass, sir."

We felt very happy, and smiled so benignly on the next hackman we met that he offered to carry us for 10 cents. We had been mad all day at hack-drivers on the American side for trying to prevent us from earning three dollars with our good walking apparatus. We had made up our mind, however, to keep out of hacks, and did so to the end of the day.

About as restful an experience as we had at Niagara was riding uphill backward on the inclined railroad. We felt so well over it that we were on the point of walking clear down the long stairs to ride up again; but a quarter for a ride was too much for us, and we gave it up. Our honest looks let us across the other bridge without an episode, and late in the evening we were landed in Rochester. We have no regrets for our Niagara visit. It is a work of nature that grows upon a person as he contemplates it in all its magnificent proportions.

After brief stops in Lockport and Rochester we were safely transported into Steuben Co., and dropped down at a little deserted way station near Bath, where silence and the darkness of a moonless and cloudy night were our sole companions. We felt somewhat discouraged; but when we made a dive for somewhere and ran into a barbed-wire fence, we felt most wretched, especially where we ran against the fence. We collected ourself together, so to speak, and after meditating around in the mud and against various kinds of fences for an hour, we at last found the house we were seeking—the poorhouse. We were saluted with a husky, spasmodic bark of an overfed dog, who said, "Tramp! tramp!" just as plain as talk. Tramps of all sizes, and variegated colors and

conditions, call nightly upon this institution; and as the dog could not see our honesty he was perhaps excusable for calling us "tramp, tramp." We turned our camera up endwise and sat down on it to rest and consider. The governor of the institution, however, put in an appearance, and learning that the Rambler was the benighted traveler we were happily entertained, and all owing to the fact that the keeper's wife was the Rambler's cousin; and we found a home here, off and on, for nearly two weeks.

Bath is conceded to be one of the pleasant villages of Western New York. It is characterized by broad shady streets and many beautiful residences. The town is chiefly noted from the institutions established here, among which may be mentioned the Davenport Orphan Asylum and the New York State Soldiers' Home, the latter accommodating in its many fine buildings about 1200 old veterans, and the beauty of the grounds and cleanliness of the buildings, and abundance and quality of the rations supplied, it is a home indeed. Bee-keeping is not a very extensive industry in and around Bath. Mr. J. H. Hadsell has an apiary in the suburbs of the village, where he attends to bee-keeping and fruit culture. His small farm is almost entirely devoted to small fruits. He uses the old-time Kidder hive, which in external appearance is much like the Dual hive recently adver-

J. H. HADSELL'S APIARY.

tised in GLEANINGS. He uses the hive both single and double walled, and winters on the summer stands. Mr. H. uses an old-style 1½-lb. section in pairs, which must be sawn apart before putting upon the market. Comb honey was selling at 10 and 12 cents per pound. Mr. H. was very pronounced in his opinions about small bee-keepers who allowed grocers to set the price upon their products. He could sell extracted honey at as good prices as comb honey, and proposed to raise more of it in the future. He said sulphured honey was liable to produce colic, and cited several instances to prove his position. As a substitute for fuming, he prevented miller-worms by keeping comb honey in a cool dry room, in a temperature not above 60°. Mr. H. invented and patented a honey-strainer several years ago, but the sales did not amount to much, and he evidently looked upon it as a past folly, and did not wish to say much about it. Thus, how often our pet schemes of one period become a thorn in the flesh later on! There were other bee-keepers in the vicinity of Bath, but mud and rain prevented the extension of our acquaintance in that line. Mr. Henry Peacock, a helper at the county house, should not be passed, for his apicultural experience was brief but thrilling. A few swarms of bees were under his management; every thing went well until one day, while hiving a swarm, an old dead apple-tree limb caught the hat and

veil from his head, "and," said he, "it seemed as though half the swarm made a dive for my head."

"I suppose you rushed for the nearest bushes, or the cellar, to get rid of them."

"HEN" PEACOCK IN THE WATERING-TROUGH.

"No, I didn't. I went for the nearest thing, and that was the watering-trough, and plunged in all over."

"Ha, ha! that was splendid. Did it get the bees off?"

"Oh, yes! it cooled them off, and me too. I soon crawled out and ran for the barn, where I combed a few out of my hair. I have never managed bees since, and want nothing to do with them."

"Lucky Peacock!" thought

THE RAMBLER.

VERTICAL VS. HORIZONTAL BEE-ESCAPES.

THE DIBBERN ESCAPE A FAILURE WHERE THE OLD-STYLE REESE SUCCEEDS.

Since reading friend Doolittle's unfavorable opinion of the utility of bee-escapes in GLEANINGS for Aug. 1, I feel it a duty to give my experience. After a fair trial I found the horizontal has been a failure; while the vertical cone, as I use it, is all that I can desire. Without its aid I could not have managed my bees without assistance. I am a practicing physician, and it so happened this summer, that, just as white clover opened (our only source of surplus), an epidemic of measles and dysentery visited us, keeping me on the road almost continuously during flow. Only a few of my queens being clipped, most of my swarms went to the woods. But, to my subject, bee-escapes:

Having given Dibbern's horizontal repeated trials with failure, and being compelled to have some aid along that line. I at once made several vertical (after Reese's plan). With these I find two things necessary for perfect work: First, there must be an air-space between the escape-board and brood-nest. Second, the opening at the apex of the cone must be of good caliber, not less than $\frac{3}{8}$ of an inch.

Take a board the size of your section-case, and in its center insert a wire cone having a $2\frac{3}{8}$ -inch base, 3 inches deep, with an opening for exit at the apex not less than $\frac{3}{8}$ of an inch. Tack the board on an empty case, and you are equipped for business. Now, just before sunset go to your hive having sections ready to come off. Don't take a smoker with you; lift off gently the full super, bees and all. Set the escape in its place on the honey-board, or, in its absence, on the brood-frames. Set the full super on the escape, then put on the cover. Very early next morning, take off your case and

take it to the honey-room. Now remove the escape, and with a gentle puff or two of smoke drive the bees below the honey-board. Put on your case of empty sections, and the work is done, and with no loss of time to the bees, and comparatively none to you. I would say to friend Doolittle, that there will be no young bees remaining behind to be lost. In taking off over 500 lbs. by this method I do not think the average was half a dozen bees to the case, sometimes only one or two of what my wife fondly styles "baby bees." I am possibly oversanguine, but I really believe that, in the near future, even now, the procuring of comb honey will be attended with less trouble and expense than extracted.

WM. S. ADAMS.

Guys, Md., Aug. 18.

BEE-ESCAPES A SUCCESS.

I have been looking for some time in the different bee-journals for some reports of the horizontal bee-escape; but as yet not much has appeared; and I am a little surprised to learn that some have met with failure. I became much interested in them last winter, when so much was going the rounds in the bee-journals, and looked forward with much interest to the time when I could test them. I thought if they would work as represented they would be a great help in taking our surplus honey. I sent 50 cts. to Mr. Dibbern, and procured a sample of his horizontal escape. It was very nicely made, and looked as though it would do all that was claimed for it. But I did not like the exits being on a level with the tin, to which it was soldered; and I could not see but that a single cone would work just as well as a double one. I made five or six after my own plan, with single cones, the cones projecting away from the tin, with the intention of testing all of them when the time came. Now for the result:

In the morning, while it was yet cool, I took my smoker and escapes, and went into the beeyard. I went to a hive on which was one or more cases filled, or partially filled, with honey, which I wished to take off. I removed the top case, and placed the escape on top of the other, or on the top of the hive, as the case might be. I then replaced the case of honey on top of the escape. I proceeded in this way till my supply of escapes was all gone; and then in the afternoon, or late in the evening, I went around to each hive on which an escape had been placed, and took off the cases of honey, and carried them to the honey-house, a great many of them without a single bee in, and some with a few bees in, with the exception of three or four cases. These I left on for two or three days, and then took them off with a good many bees in. I can not tell why the bees did not go out of them, unless they were mostly young ones. I had the Dibbern escape in use all the time with the ones I made myself. The Dibbern escape did not seem to clear up a case of bees as soon nor as clean as my own make. The bees seemed to find their way back in. On one occasion, when I had taken the Dibbern escape off a hive, a considerable number of bees were on the under side of the escape. I held it in my hand a few minutes to see if any of the bees would find their way back through the escape, and in that short time four or five bees found their way back through the escape. The exits being on a level with the tin, and the exits of both the cones being directly opposite each other, and so near each other, if a bee finds its way in through the first cone it passes on directly through the other cone and back into the super. In my escape the exit is away about a bee-space from the tin; consequently it is not so easily found by the bees.

Perhaps I should say just here, that I made

another escape that worked very well. It is simply a frame the size of the top of the hive, and about 1½ inches high, with two or three cones made of common wire cloth tacked over so many three-fourths-inch holes in one end of the frame. The cones were made about 1½ inches long. These escapes were put on the same as the others, with the cones turned to the front of the hive. In about half an hour the bees could be seen rolling out of the cones as fast as they could get out, and down over the front of the hive, into the entrance below. The only objection to this kind of escape, that I could see, was, robbers might find their way in, but I think not to amount to anything, and they are not so easily taken care of, as the cones are in the way, and are in danger of being mashed.

I regard the bee-escape as one of the best inventions of the day. What the improvements will be in the future, remains to be seen.

Millsboro, Pa., Aug. 14. OSMAN MCCARTY.

FURTHER TESTIMONY.

In response to the editor's call for experience with bee-escapes in getting bees out of supers, I am able to report that the *new* Dibbern horizontal bee-escape is a success. The escapes are to be adjusted under the supers, and left on over night. In the morning the supers will be found nearly or quite rid of bees. In one case, three stories of my hive full of honey and bees were cleared in one night, so that there were only a dozen or two bees remaining. There seemed to be no disturbance to the colony, and work was resumed as if nothing had happened.

The supers are, however, not so quickly or so completely emptied, as a rule, when the escape rests only ¾ of an inch above the frames as where a rim one or two inches deep intervenes between the escape and the hive. With the shallow rim beneath the escape, the supers will generally be found cleared of every bee the next morning. The rims I used were 2 inches deep, and have various other uses in the apiary, as in the introducing of queens, in shipping, etc.

It is somewhat remarkable that the bees do not bite into the cappings of the honey by the new mode of clearing supers. This fact alone is worth considerable to the bee-keeper, as by no other method except one can the bees be prevented from mutilating the cappings. Every one of the plans recommended by friend Doolittle, on page 555, are open to this objection, and are regarded as impracticable to bee-keepers in general where the honey is to be taken expeditiously and in good order.

There is but one plan I know of to get bees out of supers with smoke successfully, and it is as follows: Make a frame 4 inches deep for a stand, and wide enough so as to stand the supers up endwise. Nail at each corner a leg one foot long. Place this stand near the front of the hive. Now light a good smoker, lift the cover of the super off, and smoke the bees down. Hand the smoker to an assistant, and lift off the super and place on the stand. While the assistant works the smoker, vigorously throwing the smoke through the sections, the apiarist takes a hand brush-broom, and by quick movements brushes off the bees in front of the hive as fast as they come out of the super. In less than two minutes every bee can be driven out. The assistant then carries the super to the honey-house, while the apiarist takes off another super and places on the stand, or moves to the next hive. By this plan the surplus honey of a large apiary can be taken off in one day, and in the best of order, and without bother from robbing.

The objection to the plan is the rough and cruel treatment necessitated to the bees. I con-

fess not to have been in favor of the introduction of bee-escapes; but the Dibbern bee-escape overcomes my anticipated objections; and believing that our bees deserve humane treatment at our hands, I shall use it hereafter in taking off my honey.

Dr. G. L. TINKER.
New Philadelphia, O., Aug. 15.

STILL FURTHER TESTIMONY.

On page 556 I find the following: "I hope, if they are not already what they ought to be, that some inventive genius may find out where the trouble is, and give us an escape that can be placed under a case of sections or an extracting-super at night, and rid it of bees before morning."

While I think that Mr. Doolittle will find that we can never get an escape to work just as he has stated in the above sentence, I wish to say that that "inventive genius" has already put in his appearance. I have been using bee-escapes all summer, and they have given me such satisfaction that I feel safe in saying that such escapes as I am using will give as much satisfaction in a practical way as T supers or bee-smokers. While bee-smokers will occasionally go out or burn out just about the time we need them most, they are indispensable to success in keeping bees. So with T supers: while they are objectionable in some respects, we can not dispense with them until we find something better to take their place. And we have a bee-escape that will get the bees out of surplus-receptacles, and *keep* them out; but I have found, that, when the escapes are placed on the hives late in the evening, or even after the middle of the afternoon, but very few, if any, of the supers will be cleared of bees by daylight or sunrise the next morning, simply because the bees appear not to be inclined to change about or leave the supers during the night.

I have taken off over 1800 lbs. of comb honey with as little inconvenience, and less trouble with bees, than I usually experience in taking off 100 lbs. By adjusting the boards in the morning, say from 7 to 9 o'clock, the supers will usually be ready by 1 or 2 o'clock in the afternoon; and, if the boards are immediately adjusted under another set of supers, these can be removed early the next morning, thus using the same escape twice in one day. The honey-flow, conditions of the weather, and the disposition of different colonies of bees, all these have their influence, and tend to make up a varied experience in the use of bee-escapes. Colonies that are quiet and not easily disturbed are slow to move out of the supers; and hives that are overcrowded with bees, if the weather confines them to the hive, will so choke up the outlets of the escapes that the bees in the supers appear for a time to be unable to force their way out. But these are exceptional cases; and in the latter, two escape-boards, placed one on top of the other, soon clear the super.

The cone escapes can not be made satisfactory. I have used cone escapes that are much superior to the Reese or Dibbern patterns, which have worked reasonably satisfactorily under ordinary conditions, but in every-day work the bees find their way back through them more or less. What is wanted, and what I have been using for nearly three months, is an escape that will permit the bees to pass out easily and rapidly, and at the same time allow no bees to return. The inventor of these escapes is a bee-keeper of this county; and while he is endeavoring to get up something that is of practical utility, he is in no hurry to offer escapes for sale, preferring to give them the test of a whole season's operations.

S. A. SHUCK.
Liverpool, Ill., Aug. 23.

MORE ON HORIZONTAL BEE-ESCAPES.

In regard to the working of the horizontal bee-escape, friend Dibbern's four-point escape is not a success. Mr. D. has a new tin escape that works nicely. I have been testing it for two weeks. It will rid an extracting-super in two to three hours, and the bees stay out. It will clean the bees out, even with brood in combs; but they are longer in leaving. The hives were full of bees, and I did not put on an empty super, so you see they went down into the hive already crowded with bees. I was much pleased with the first one Mr. D. offered for sale, and I made up a lot of 25; but I was soon disappointed, for they did not clean a case of honey in a week. But I found a use for the boards, and will keep them for introducing queens, feeding, and covers for super cases.

Unionville, Mo., Aug. 16. E. F. QUIGLEY.

HORIZONTAL BEE-ESCAPE A SUCCESS.

You ask for accounts of the use of the horizontal bee-escapes. I am very much pleased with the working of mine. With them I can take off my honey without any use of smoke or disturbing the bees, or exposing the yard to robbing. I prepare the board to fit in the inside of a super, resting on the tins which support the frames. An assistant takes the super thus prepared, and stands ready to slip it on the hive as I lift the super with honey, and then place it on the super containing the escape. The whole operation takes but a moment. The next day I take the top super away undisturbed, and leave the escape till I prepare them for winter. A small piece of burlap takes the place of the tin; and this covered with a woolen quilt, the winter work is done.

G. A. ADAMS.

Perrysburg, O., Aug. 14.

HORIZONTAL BEE-ESCAPE ALL RIGHT.

I see by GLEANINGS that the horizontal bee-escape is not working satisfactorily for friend Doolittle and others. I am using it, and with good results. I made my escape-board so as to give a double bee-space between it and the sections or frames below. The escapes were made so as to give $\frac{3}{4}$ of an inch space between the sides of the inside and outside escape. If I make any more escape-boards I shall try a full inch space between it and the hive or case of sections below. The bees will not cluster so thick on the escape, and will not be so apt to find their way back into the upper case of sections.

My bees are doing well. I have secured 150 pounds clover honey (comb) from five colonies, spring count. I expect twice that amount from buckwheat and fall flowers.

D. I. WAGAR.

Flat Rock, Mich., Aug. 8.

ANOTHER FAVORABLE REPORT.

As you ask for reports on bee-escapes, and as I used six Dibbern improved escapes, I report that I found them a success under section honey every time. When used under extracting-cases I met with two failures; but on examination I found in one case there was brood; in the other case, no perceptible cause, so I count only one failure. Of course, there were sometimes from 12 to 20 bees that had not worked out—never more, and frequently none. Few inventions are perfect. With me the bee-escape is as near perfect as the bees themselves, for they have failed here right along. From 40 colonies, spring count, I have 1200 lbs. extracted and 350 lbs. comb, and no rain to insure honey. Never before have I had unfinished sections of comb honey enough for bait the following spring; but I have them now to spare. Well, they are not the trouble I expected them to be. I cut

them out and fill the cracks with extracted honey, and they go like hot cakes in my home trade. I shall have no other this year. In fact, I shall lack at least one ton of enough extracted honey, and probably be 1000 lbs. short on comb honey. I have been trying to buy, but so far I have not succeeded in getting an article that I felt justified in buying at prices asked.

Moberly, Mo., Aug. 9.

J. RICHARDSON.

BEE-KEEPING IN NORTH CAROLINA.

A VISIT REVEALING EXCELLENT TERRITORY,
WITH FEW BEES AND POORER METHODS.

As per promise, I will send you a few notes gathered from a tour of the mountain counties of this State. In company with a friend I took leave of this, a rather central location, to see what could be found of interest in the line of the bee-industry. The first thing to impress us was the extreme scarcity of bees. This fact is the more striking when we are forced to conclude that these mountain counties are the very paradise of the honey-bee. The famous sourwood, which is the basswood of the South, abounds on every hand. Then there is a long list of nectar-producing plants and trees that give an almost continuous flow from February till frost. There are immense tracts of forest that will remain such, as the lands are not fertile. We found a few bee-keepers who had in use the Mitchell, or "adjustable" hive, and the old American. All claimed to be using patent hives, for which they had paid.

The first call we made was with a good brother bee-keeper who claimed to have 150 colonies, all in the Mitchell patent division-board-adjustable-reaction hive. He said he was very much wedded to this hive, but he said his confidence in the inventor was not as strong as in days of yore. We were so completely dumbfounded when this friend told us that he had never used a bee-smoker, nor taken a bee-journal, that we forgot to hand him a copy of GLEANINGS from our grip, and also to show him a Clark smoker we had with us. In justice to this friend, we must say that he owned up to having had a copy of King's text-book, but that he had not seen it in years. We will take leave of our good host when we say that his success in bee culture is not the kind that succeeds, taking his own statement for it.

We made a few minutes' call on another bee-brother who has about 20 colonies in the American hive. His bees were too high for the weeds to trouble. His crop of honey last year was fine, but had in a measure failed this season. On being asked if a good crop once in two years did not pay him to keep bees, he said it did. We gave this friend a copy each of the *American Bee Journal* and GLEANINGS. These men are about a type of the bee-keepers of this, as good a field, all things considered, as can be found south of the Mason and Dixon line. Almost all have the black bee.

We heard the most remarkable stories in regard to the fall of honey-dew during last winter. One reliable man told of his pants becoming coated while rabbit-hunting in the sedge-fields. We should like to hear what Prof. Cook has to say in regard to a winter crop of honey-dew.

Our bees had begun to nose around the cotton bloom before we left, and, to our pleasant surprise, we found them fairly rich, all from this source. One-third of this time was very rainy too, so bees had only about ten days to get from a starving condition to a comparatively prosperous one. This was so only with colonies that kept brood-rearing right along through June.

I am glad to say my dish was nearly right side up. Our cotton honey is excellent in quality. I will mail you a sample soon.

The Dovetailed hive is being introduced here, and will, I think, become popular. Friends Cauthen, Simpson, and myself, have been using this hive for several years—the same except the dovetailed corners. A. L. BEACH.

Pineville, N. C., Aug. 14.

POPULAR.

CAN WE FIND A SUBSTITUTE FOR BASSWOOD FOR SECTIONS?

I have noticed considerable stir among our Northern bee-writers in regard to the consumption of basswood timber for sections and other purposes; and some are taking measures to withhold this rapid destruction of the timber, and suggesting substitutes for it. This is certainly the proper thing; but we should move slowly, be sure we are right, and *then* we can go ahead with the minimum of friction.

I greatly fear that those who have discontinued the use of basswood sections, and adopted poplar (or tulip) as its substitute, have not bettered the matter very materially, so far as the general welfare of the bees is concerned. Our Northern friends do not seem to realize fully the real value of the poplar as a honey source, perhaps on account of its scarcity there. While basswood is *very* scarce here in Southern Ohio, poplar fills its place, and fills it well. I do not know very much about basswood as a honey-producer except as I read what is reported through the journals; but I should not hesitate to say that poplar will at least "hold its own" with basswood, every time. White clover is perhaps at the head of the entire list of honey-producing plants, as A. I. Root says in his A B C. Yet bees in this locality gather as much honey from poplar in fourteen days (the average length of time of poplar bloom) as they do from clover in fifty days (the average length of time of white-clover bloom). I feel certain that the fully developed blossoms will average half of a teaspoonful of nectar; and when the trees are in full bloom, the bees get themselves all daubed, just as they would if they were taking honey from a dish. So those to whom the poplar is a stranger can form some idea of its honey-yielding properties. But the honey is not such a fancy article as that from white clover or basswood. In color, it is a little dark, or golden. After all, this is no serious thing; for coming, as it does, between fruit and clover bloom, the bees make use of most of it in filling up the brood-chamber, so we do not get a great deal in the sections.

But here is the point: There is a period of about three weeks between fruit and clover bloom, during which the bees could not get enough to run them, and would have to be fed during the whole time to make them prosper properly. But as it is, we are not compelled to feed. We have just the thing we want. Instead of feeding to keep up brood-rearing, the bees are rolling in the dark poplar honey until they have the brood-chamber crammed full, and many are already up in the sections ready for the whole crop of clover honey, which follows close, for surplus.

It is hardly worth the space to say that our poplar is, and has been for some time, meeting the same fate as the northern basswood: indeed, a *worse* fate, for, as every one knows, poplar timber is being used for purposes almost innumerable. J. C. ATKINSON.

Nelsonville, Ohio, Aug. 18.

Friend A., your points are well taken. The

destruction of the forests is certainly going to have a marked effect on bee-keeping as an industry; and unless forests are planted, or fruit, or some other honey-bearing trees, in sufficient quantities, there is trouble ahead.

DO BEES CHANGE NECTAR?

PINE-TREE HONEY.

In your reply to D. A. Rothrock, July 1, you say that bees do not change the nectar in carrying it from the flowers to the hive. Last winter I sent you some samples of pine-tree honey-dew, and I now send a sample of honey made from it. I know it is genuine, as I placed an empty comb in the hive, and extracted the honey from it; and as it was in the winter, there was no possibility of their getting honey from any other source. You will observe that it has a "honey" taste, while the honey-dew tasted more like sugar syrup. It is darker (it was not as dark, however, when first extracted), having stood in a bottle since March. The honey-dew I had collected in vials soured; this does not. When the honey-dew had collected on the bark and evaporated, it left a lump of what looked and tasted like white sugar. I don't think this will. If you feed bees honey, what can they store but honey? and if it is scorched, or bad in any way, of course it remains so; but I can not think they store any thing but honey, no matter what they collect, and said honey is of different quality and taste, according to the substance from which it is made. You are very positive and earnest in denying charges of the

ADULTERATION OF HONEY

by feeding bees. Are you sure that some of the large quantities of sugar that we read of some apiarists feeding to their bees is not taken out and sold as honey, and that there is not enough margin for a fair profit between the prices, when sugar is bought by the wholesale? We have had no surplus honey as yet, as there was but little of any kind of bloom in the spring, and the honey was mostly consumed in breeding, which was very early and profuse. The honey-dew appeared again, however, about July 15, and they are now booming.

Amherst, Va., July 31.

J. OSBORN.

Friend O., we are all very well aware that bees evaporate, or ripen, honey in the combs; and we also know that well-ripened honey is very different from the raw nectar, as gathered from the flowers. This ripening process can be done artificially, nearly if not quite as well as the bees can do it. The raw nectar from the spider plant has a green, sickish taste, or something that way, when you gather a spoonful or two; but hold it in a spoon over a lamp until it evaporates, so as to be as thick as thick honey, and it has a very delicate, pleasant flavor.

In regard to feeding bees to get honey, all that is needed to show the folly of such a course is to try it. See what is said in the A B C book in regard to feeding honey back to get sections filled up. I don't think there has ever been a time when any bee-keeper could make it pay to feed his bees sugar so as to sell it for honey after they had sealed it up in the combs. The matter has been discussed in our journals for 20 years back. We may feed cheap

sugar to keep the kees raising brood so as to make it pay, without question; and many bee-keepers do this, but no bee-keeper is now feeding sugar in order to get something to be sold as honey. He will surely become bankrupt if he keeps on at it.

QUEENS LEAVING THE HIVE.

DO THEY DO IT?

Do laying queens ever leave the hive, when not accompanying a swarm? My experience is, that they sometimes do. The present season I have about thirty hybrid colonies that I bought last spring; and wishing to raise queens to sell I am using an Alley drone-trap on each hybrid colony, to keep the drones shut in. In the past week I have found the queens of four colonies dead, in the upper apartment of the drone-trap. It is possible, but not probable, that the queens died and were carried there by the bees. They were all young laying queens, raised this year, and were purchased of one of our most eminent queen-breeders, and had been introduced and laying at least three weeks.

My bees have been working on buckwheat, and swarming, the last two weeks; but I have never been out of sight of the bees long enough for them to swarm without my seeing them, so I do not think it probable that they got into the trap by going out with a swarm.

By removing the wire nail that closes the opening between the upper and lower apartments of the drone-trap, the queen could return to the hive; but that would let the drones back too, and one would be obliged to keep the traps on all summer to keep the drones in.

In C. C. Miller's article in GLEANINGS, Aug. 1, page 559, he asks, in conclusion, why the queen does not lay drone eggs in incipient queen-cells where they surely would have elbow room. In my eight years' experience in queen-rearing I have found queen-cells built on drone comb several times, and that, too, when the bees had worker eggs in plenty to build cells on. As I was anxious to know what kind of an animal they would hatch, I watched them closely, but they invariably failed to hatch at all, the larva always dying in the cell before hatching.

ELMER HUTCHINSON.

Rogersville, Mich., Aug. 19.

NOTES FROM RHODE ISLAND.

THE HOFFMAN FRAME, ETC.

Although "Little Rhody" is not much of a honey State, its bee-keepers pride themselves on keeping abreast of the times in the apicultural world. They are constantly trying new paths and short cuts, and endeavoring to outstrip their neighbors of "wooden nutmeg" fame, and leave behind "ye pilgrims of ye olde Baye State." We bee-keepers about the shores of beautiful Narragansett find we must modify systems successful elsewhere, to fit our climate and flora, which, to say the least, is often erratic.

This year there was a good flow of honey all through July, coming from an early variety of goldenrod and two varieties of spirea. This July flow is unusual, bees generally having to live on what they have laid away. To be always ready for these irregular flows we have to keep the queens constantly at work. August and September seldom fail to bring good flows. Perhaps when I say that, in three of the best apiaries in the State, the Hoffman frame is

used to the exclusion of all others, you will think some of us are progressing backward. Be that as it may, the owners of these apiaries will now tolerate no other style, except for experiment.

If you will try the standard Hoffman frame beside your modified style, you will, I think, be convinced of the points of superiority of the standard as explained by Mr. Hoffman in GLEANINGS for July 1st.

I find the same trouble with a deep ($1\frac{1}{2}$ inch) space under the frames as does Mr. Hatch (Aug. 1, p. 561). During the past three seasons, with from 1 to 20 colonies so arranged, the result was always the same.

If Ernest will take foundation partly drawn out, and try his experiment of stretching while it is yet warm and soft from the heat of the hive, the result, perhaps, will be different.

As for the way bees build their comb, they do not always go "according to Hoyle." I took from a colony a few days ago a new comb, one-third of which was built as it should be, and the other two-thirds as it is said it should not be. It was built on a new clean frame without any foundation or guide whatever, and by a good thrifty colony in normal condition. That colony evidently needs educating. But once have I had drones driven out in June (1889) when honey was fairly plentiful. I ascribed it to an unusual scarcity of pollen; for as soon as that became abundant again, the drones were undisturbed.

ARTHUR C. MILLER.

Providence, R. I., Aug. 9, 1890.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

HONEY FROM COBEA SCANDENS.

One fine morning I noticed on my porch some drips that I couldn't account for; porch rather dusty, and there were the drops, eight in number, and not a sign of any thing to show from whence they came (I thought). It was mysterious to me, as my folks had been away from home some two months, and I thought more or less about it all day. The next morning I found the porch fairly spattered with it; and tasting, I found it honey. In a moment it flashed on me (flowers). Covering all the porch are luxuriant vines of *Cobea Scandens*, whose bell-shaped flowers are daily loaded with honey, clear as crystal. It took the bees about two days to "tumble;" but now as many as five at a time can be found in a single flower, and every morning the drops hang and glisten so plentifully you can gather it with a spoon. It is something new to me, or at least I've failed to notice it heretofore.

The season is poor for surplus, fair for increase; some few swarms coming, even this late. As usual, Italians in the lead.

Portland, Or., Aug. 7.

E. J. LADD.

A NEW USE FOR PERFORATED ZINC.

The honey crop is small this year. From 200 hives, fall count, I have extracted 1500 gallons; cause, too much swarming late in the season, when they should have been gathering honey. I have found a new use for your perforated zinc. I place one on a weak two-story hive. I have the small swarms in the common wooden water-buckets, and set them on the zinc. The bees will go down through the zinc and leave the queen on the zinc. By doing this, weak hives can be made very strong. I then keep putting on top hives, and hiving small swarms, and I have no trouble about fighting, as the bees are

gathering honey. The above is very old to the veterans, but new to the A B C's.

I see much in the bee-papers about planting for bees. Almost all say it doesn't pay. I have been experimenting a little on that line. I got half a bushel of white-clover seed of you. I sowed it in February and March, 1889. Not a seed has been seen since. White clover does grow here. Bees work a great deal on mustard. It is almost a constant bloomer, if planted, say, every 15 days. J. W. PARK.

Columbia, Tex., Aug. 14.

FROM 2 TO 7, AND 100 LBS. OF HONEY.

I received the queen in good condition. She now has the hive full of brood and eggs. I was much surprised to find I had sent too much for her. I have never had a pure Italian before. I started last year with two colonies of blacks in rack hives. I got from them 7 swarms and 100 pounds of box honey. They wintered well, but I lost one this spring. I have had 12 new swarms this year, but will get no surplus, on account of the dry weather. It has been very dry. I had to feed during white clover. I think they will winter if we get some rain. My bees, both blacks and hybrids, are very gentle. They hardly ever sting unless I pinch them. If my queen lives I am going to try Italians another summer. I hear them praised so highly I will report how I like them. E. J. BARBER.

Corinth, Miss., Aug. 13.

ARE BLACK BEES LESS LIABLE TO DISEASE?

I have 100 hives of black bees. I don't doubt but that the Italians would make more honey. I have never seen a case of foul brood, nor heard of any in this part of the country. Possibly there is no connection between having all black bees and no foul brood. Won't you please answer briefly the following questions?

Are not black bees proof against foul brood, sometimes, when Italians are not?

If Italians are more prolific than blacks, are they not also more inclined to swarm frequently? J. S. CALLBREATH.

Rock Rift, N. Y., July 4.

Black bees are no more proof against foul brood than Italians. In England and Germany, where black bees are the prevailing race, foul brood has made its mischief for many years.

As Italians often get honey when common bees do not, they sometimes swarm when common bees do not.

A CORRECTION IN NOMENCLATURE.

I have just been reading GLEANINGS, and I notice an article on page 526 upon "Apicultural Nomenclature," in which the writer, in trying to correct one error, has fallen into another. The writer states that "cottonwood, balm of Gilead, and quaking aspen, are all different trees, though very nearly allied to each other. The poplar is of another and distinct type." Partly right and partly wrong. Botanists, for convenience, have grouped all plants, including trees, into families; and again some of these families are divided into sub-families. The willow family is one which has a division, and one of the parts, or sub-families, is called *Populus*. In this division are found several members—two aspens, the American and large-toothed; five poplars, the downy, balsam, white, Lombardy, and necklace (the last of which is called cottonwood), and the balm of Gilead. These are all different trees, but closely allied, as Mr. T. states, only he should have included the poplar. He says the poplar and tulip-tree are the same. Now, the tulip-tree belongs to the magnolia family, and that is about as near

like the willow as the rose is like the milkweed family. Prof. Asa Gray says, that in the West the tulip-tree is wrongly called the poplar. There is no tree named whitewood, but it would seem as if all trees whose wood is white are in certain places called whitewood.

Geneva, N. Y., July 25. PATTIE MASON.

MAKING HIVES AND FIXTURES BY HAND; BEST HONEY SEASON.

I have made 100 hives, all of the frames, and 2000 sections and 1600 separators, all sawed by hand power, so you can see that I wished I had a good engine more than once. I have now 118 stands of bees. I took off 340 lbs. of honey, and have about 1000 lbs. to take off this week, all in 1-lb. sections. The honey is the whitest I have had since I have had bees, and the best honey season so far.

THE WORK OF BAD BOYS, AGAIN.

I had to go out and fix up a hive that two boys were trying to steal honey from about an hour ago. It is 12 o'clock at night now. I hope you have not any boys of that sort out there. If they had wanted honey, and had come to the house, I would give them all they wanted to eat. As it was, the bees were not asleep, and they lost their honey, and had a lively run.

Dover, Mich., July 28. A. N. WHITLOCK.

QUEENS LOST ON RETURNING FROM THEIR WEDDING FLIGHT.

I have been losing a good many virgin queens during mating this summer. I had a nucleus in an observatory hive, and saw the queen take a flight about four o'clock. She came back in about five minutes, successful. Immediately on entering the hive she was balled; and as I did not suspect any thing wrong she was killed in a few minutes. Is it a common occurrence, and is that the reason I have been losing so many virgin queens?

The horizontal bee-escape has worked well with me this season, nearly all the bees being out of the sections in the morning, if put on at night—perhaps a few in one or two sections.

LLOYD SECHRIST.

Pleasant Home, O., Aug. 6.

Friend S., such things are not very common, although they do happen, especially when there is a dearth of honey. I have never known it to continue long enough to do much harm. I have sometimes thought it was caused by placing hives so close together that the bees were in the habit of mixing, until they get into a quarrelsome frame of mind.

CATCHING QUEENS BY MEANS OF THE PERFORATED ZINC.

Here is a quick way to catch black queens, and it will work equally well on any kind of queens. Take one sheet of your queen-excluder, say 13x20, make a box two inches deep, with bottom and sides of thin stuff—no cover. Now make one the same size out of 1½ stuff, ¾ wide; now nail on zinc excluder for the bottom, and the thing is made. Take it out into your bee-yard; set it down about a foot in front of a hive, the deepest part first; then put on the zinc with the rim up, to keep the bees from running off the sides; then use a little smoke. Pick up the frames with the bees all on. Now, do not stop to look for the queen, but give it a quick shake in the box on the zinc, then take another the same, and so on, as fast as you wish to, and you will soon see the queen on the zinc. The bees have gone through as fast as shaken on in the box below, leaving the queen in plain sight. Pick her up, shut up your hive,

pick up your zinc, shake it in front of the hive, the box the same. All can be done inside of two minutes. It is quick, easy, and robber-bees have no time to find what you are at before the thing is done. We have caught 16 in two-story hives, in 28 minutes. Try one; and if you do not laugh, charge it to me.

Fulton, N. Y., Aug. 12. OSCAR DINES.

Friend D., the use of sieves with a bottom of perforated zinc is very old. Quinby described it, if I am not mistaken, in one of the first editions of his book. Your arrangement, however, seems to be a very convenient one. We have used such devices to some extent; but as *we* ordinarily find our queens in less than a minute, it would hardly pay us in our business. *Our* colonies, for the purpose we use them, and with the *metal corners*, are very easily looked over.

WHAT WOULD BE PROPER RENT FOR 500 COLONIES?

If I should own an apiary of 500 or 1000 colonies, and should not desire the care of it, for what could I rent it in cash, the renter to have honey yield and none of the increase? Would it be best to have so many colonies of bees together, or would it be best to separate into apiaries of 500 each, several miles apart? My apiaries would be in Colorado.

MISS LIDA WINSLOW.

Carthage, Ind., June 28.

My friend, I do not know how we can answer your question. In the first place, I do not believe in renting bees. Sell them outright at some price, and have it done with. If, however, nobody around you is willing to buy, but is willing to rent, I would put it like this: For instance, the renter is to take 500 colonies of bees, and turn them over to you in one year, in as good condition as he found them. Let him pay you as rent the ordinary rate of interest on the value of the bees, as nearly as you can give on a fair valuation. Then let him have every thing he can get out of it—honey, increase, wax, and every thing else. If you undertake to put in a lot of conditions you will complicate the matter and open the way to no end of dissatisfaction and complaint, perhaps on both sides.

SELLING HONEY BY THE SECTION; WIRING FRAMES, ETC.

The grocers in Middletown, this county, so far as I know, buy honey in sections by the pound, but many of them sell by the section, and not by weight. I have tried to convince some of them it was not a fair way of selling, but it is less trouble, and that suits them.

I have a nephew in business in Honesdale, Pa. I was there last winter. He was selling sections at 15 cts. each; paid 12 cts. per pound for them. They did not average near one pound in weight. As far as my observation goes, fully as many sell by the piece as by weight.

In using tin bars in wired frames I set the edge of the bar against the foundation and not the flat side. It takes up little room, and is not in the way, for the bees build up to it and cover it all over. I use 7 instead of 6 upright wires, having one in the center, the tin bar on one side of the sheet, and the wire on the other. Your old way of wiring frames can't be bettered.

Will some one who can do it, please tell in

GLEANINGS how to get the bees to carry the honey from partly filled sections to the body of the hive when they need it for winter stores?

I have a fair crop of honey this year. I have been in the business here for 11 or 12 years, and in that time have always got some surplus, and with the exception of two seasons, have had good crops.

E. D. HOWELL.

New Hampton, N. Y., Aug. 8.

Friend H., I fear I shall have to give up that honey is sold by the section a good deal. Notwithstanding, I think it is a wrong way of doing business. But it seems to me that the dishonesty lies on the grocer and *not* on the bee-keeper. We can not well make our sections to average a pound, very closely, or any thing very near it.

NOTES AND QUERIES.

DIBBERN. BEE-ESCAPE—A GOOD REPORT FROM.

I would say I have used the Dibbern bee-escape, and it gives good satisfaction by putting it on in the evening. The bees were all out of the T super excepting about $\frac{1}{2}$ dozen the next morning.

D. BECKMANN.

Wheatland, Iowa, Aug. 7.

HANDLING BEES WITHOUT SMOKE.

You speak of handling bees part of the time without smoke. I believe that with a little practice, any person could get along without smoke. I can handle hive after hive without it.

Lewiston, Mo., June 30. H. MANSPERGER.

[You can get along without smoke at times, but it takes more time. A little whiff over the tops of the frames will so mollify the bees that you can work faster ordinarily.]

QUEEN-CAGES FOR LONG DISTANCES.

What kind of cage or device do you consider the best for shipping queens long distances (say 18 days' journey)? Is it absolutely necessary to supply queens with water for such long journeys?

WM. STYAN & SON.

San Mateo, Cal.

[We prefer the Benton cage for long distances. We formerly put small tin bottles of water in the cages; but within the last few years we have not found it necessary.]

CONTRARY TO NATURE: A NUT FOR DOOLITTLE TO CRACK.

Not long since a pioneer bee-keeper was passing through my apiary; and observing a large bee (it was a drone) he said they were the *she* bees. He said he did not believe in killing such bees, as it was "against nature." Shades of Doolittle! Somebody is certainly behind the times. Doolittle says he cuts their heads off in the combs. Leading lights sometimes disagree.

Shiloh, O., July 19.

T. F. KIMEE.

[Friend K., I have got to be a little suspicious of anybody when he goes to preaching "against nature;" that is, when somebody complains that you are against nature because you *use* the intelligence that God has given you.]

NAILS AS SPACERS FOR FIXED FRAMES.

I have watched the discussion on fixed frames, to see the different methods of spacing. I take some of those wire nails, drive in the top-bar about an inch from each end, just far enough to space the frames. I have a gauge, and lay it beside the nail and drive until it is

even with my gauge. I do not remember the width of the gauge without going to measure, but that depends upon the width of the top-bars. The nails answer every purpose for me.

Shreve, O., July 18.

C. B. WAY.

THE NEED OF THICK TOP-BARS.

I lost a valuable colony of Italians by the Simplicity hive becoming so sealed between the first and second story, and not being able to separate. When the bees were dead I took severe measures; and after separating, I found the worms had taken possession. This colony had given me over 50 lbs. of box honey each season.

A. FAMARISS.

Beverly, N. J., June 14.

[This is why we look forward to thick top-bars as doing away with all this trouble. The trouble was not in the hive, but in the thin top-bars which allowed burr-combs to be built.]

SPACE BETWEEN FRAMES; IN FAVOR OF NARROW SPACING.

In getting brood into my little combs for fertilizing hives, I have experimented a great deal on space between combs, and have come to the conclusion that $\frac{3}{8}$ (a little scant) is about correct. At this space all the combs are filled to the top-bars perfectly flat and smooth. In order to maintain the space accurately we use little spacers to attach to our finger, like a thimble. All our frames are one inch all around, and cut with perfect accuracy.

Marlboro, Mass.

E. L. PRATT.

[Thanks for the result of your experience. I am pretty sure that $1\frac{3}{8}$ from center to center is not too wide, and perhaps we can do with less.]

OUR QUESTION-BOX.

With Replies from our best Authorities on Bees.

QUESTION 167.—*Will it be safe for me to ship off comb honey without brimstoning it? 2. Did you ever know worms in sections where there was no pollen?*

It may and it may not be. 2. Yes.

Ohio. N. W.

A. B. MASON.

Yes. 2. Yes, but not very often. Worms can not live long on pure beeswax.

Illinois. N. W.

DADANT & SON.

I have never shipped comb honey. 2. Yes, a few.

Wisconsin. S. W.

E. FRANCE.

Yes, if shipped early, and if it contains no pollen. 2. No, I think not.

Vermont. N. W.

A. E. MANUM.

I don't know. I have never brimstoned any. 2. Yes, brood will bring worms; occasionally a worm without.

New York. C.

P. H. ELWOOD.

Usually, yes; occasionally, no. If eggs are laid on the combs they will hatch with or without pollen. I do not think the larvæ would mature without pollen.

Michigan. C.

A. J. COOK.

The least honey we get is brimstoned. I would not brimstone my honey unless it were necessary. 2. I generally found pollen in the combs that had bee-moth in.

Ohio. S. W.

C. F. MUTH.

Yes, sometimes; sometimes no. 2. Thousands of them, where there was no visible pollen; but the microscope reveals pollen where it is not seen by the naked eye.

New York. C.

G. M. DOOLITTLE.

I have not found it safe for me to do so. 2. Oh, yes! lots of times. They are very apt to come on the edges of cells close to the wood. I have even seen them come on foundation.

Illinois. N.

C. C. MILLER.

I think so. I have raised and shipped a number of tons of comb honey, and I never brimstoned a pound of it. 2. No, nor did I ever see fifty sections with worms in from any cause.

Illinois. N. C.

J. A. GREEN.

If it has been kept for some time in a warm room I should prefer to fumigate it before shipping in very large quantities. 2. Yes, except what was contained in the honey.

Ohio. N. W.

H. R. BOARDMAN.

I am not an extensive comb-honey producer, but I have not brimstoned what little I have had. I heard no complaint from the 2500 lbs. that I sent out last season. 2. To some little extent.

Wisconsin. S. W.

S. I. FREEBORN.

If taken off in hot weather and shipped immediately there would be danger of worms unless brimstoned. 2. I have known the surface of sections to be webbed over and the cappings destroyed in many crates where there was no trace of pollen.

New York. E.

RAMBLER.

No, not at this season (early summer). 2. Yes! i. e., where there was no pollen practically—no cells of pollen; but there is a little floating pollen in most, if not all comb honey. Sometimes the amount is so small as to be undiscernible to the naked eye, and would probably cut no figure in the moth or worm question.

Illinois. N. W. C.

MRS. L. HARRISON.

Yes; if you have the right kind of bees, such as we think we have, and use proper care about your apiary and buildings, you will have no use for brimstone. I do not think I have seen a worm in any of my comb honey for many years. I believe it is a physiological fact, that the moth-worm can not develop without the use of pollen.

Michigan. S. W.

JAMES HEDDON.

I think that in most apiaries the sections are rarely troubled with worms. I would not fumigate unless there were reasons to apprehend trouble. 2. I do not positively know it, but I have the impression that they do sometimes occur. I believe it is several years since I have noticed a worm in my comb honey at all. I lay it to my farming neighbors not keeping bees, and tolerable care on my own part not to breed the mothers of the mischief.

Ohio. N. W.

E. E. HASTY.

I think I have said in the A B C book, that I would never go to the trouble of brimstoning honey until I discovered the minute worms somewhere about the honey; and I have also said, further, that with the Italian bees the fumigation is seldom if ever necessary; and I believe that a majority of the answers above pretty nearly agree to this. It just now occurs to me, that, if the moth-worm can not mature without pollen, is it very strange if the larva of

the bee can not, in a like manner, mature without pollen as well as honey for the nurse-bees?

NOTES OF TRAVEL AMONG YORK STATE BEE-KEEPERS.

AT G. M. DOOLITTLE'S.

The ride by boat on the beautiful Lake Skaneateles to Borodino was fine. The water was so clear that, just before starting, I could see large fish at a depth of 12 or 15 feet off the dock. As we steamed out into the lake, the beauty of the scenery became more and more manifest. The shores rise gradually from the water's edge, and off in the distance little towns are pointed out.

"Over in that direction," said the captain, in answer to my inquiry, "is Borodino."

Doolittle has a beautiful location, I thought. There are never any mosquitoes around this lake, I am told; and the water is so clear, and the shores so inviting, it is a wonder that the lake is not more visited by pleasure-seekers. In about half an hour I was landed on the Borodino dock. As it was rather late I put up at the hotel. The following morning found me on the wheel, sailing toward the home of Mr. Doolittle, for his place is about a mile out. I looked along the road to see if I could pick out Mr. D.'s home. That place doesn't look exactly like it. Finally, from the top of a hill I see a very pretty country residence. Every thing about the place shows neatness and taste, and the buildings are well painted. I wonder if *this* is not the place. As my bicycle travels noiselessly along, suddenly an apiary looms up in the rear. Yes, there is a bee-cave. This *must* be the place, and so I turn in. I lean the bicycle against an overspreading apple-tree by the side of the house.

"Is Mr. Doolittle in?" I inquired of a man in the barn.

"He is in the shop and will be out presently."

I strolled into the apiary meantime, wondering whether my friend would recognize me. After waiting a moment somebody steps from the shop. He has a sandy beard, and he looks like a portrait I have seen somewhere.

"Good morning!" I said. "This is Mr. Doolittle, I suppose?"

"And is this Ernest?" said he, grasping my hand. "I had not expected to find you wearing glasses."

"I have been using them ever since I left school, five years ago, and ought to have begun wearing them sooner."

Together we went into the shop. I noticed he was very careful to close the door after him; and the fact that there were no robbers about was pretty good evidence that this was his habit.

As I expected, every thing was orderly. In one end of the shop was a small boiler and engine; near the center of the room, a saw-table; beside the windows, a work-bench. Two rooms were partitioned off. One was a bee-proof honey-room, and the other a general study, or sanctum, where he can be in seclusion and write his articles for print. In the latter room he showed me his Hammond type-writer, the machine that does the nice work he sends out. I found it was very simple, and easily operated. A large telescope, mounted upon a substantial tripod, occupied a space upon the floor. The owner not only studies the handiwork of God as he finds it among the bees, but he is delighted with what he learns and sees beyond the vale of this world.

"Mr. Doolittle," I said, "I notice you are in-

terested in one of the branches of optics. Why don't you take up photography, and so illustrate your articles occasionally?"

"Well," said he, laughing, "I had thought of that very thing, but I came to the conclusion that Doolittle had no time with all his other work, to fuss with it."

When it is remembered that he does *all* his work in the apiary, wraps and directs all his queens, answers all his correspondence without the aid of a stenographer, writes regularly for several periodicals, makes all his supplies, keeps up a good garden, takes care of a horse, to say nothing of the services he renders to his church and town, we comprehend somewhat the force of the remark, that "Doolittle has no time" for another branch of optics.

He is precise and methodical in all his work, especially so in queen-rearing; and as it is not an easy matter to get help possessing all these requirements, Doolittle prefers to do Doolittle's work.

Upstairs in the shop Mr. D. has a collection of bee-implements, old and new. He showed me a box containing some old - style honey-boxes, which a few years ago, out of the kind intentions of a supply-dealer, had been sent him by *express*. The charges were \$7.50. There was no letter of explanation. Mr. D. paid the charges, and the boxes he has used for kindling-wood. At other times hives and other implements had been sent him, charges paid. He had never even opened some of these packages, as he had no use for them. I take pains to mention this right here, as we have been many times served in the same way. While all this is prompted by kind intentions, don't send stuff without first writing to see whether it will be acceptable.

But, to return:

Mr. Doolittle lighted his smoker, a Bingham.

"I suppose," said he as we started, "you don't wear a veil."

"Oh, yes, sir! I do. It's my father you are thinking of."

At this I pulled out my veil, for I carry one with me everywhere, and we together went among the bees.

We looked at the progeny of some of his breeding queens. They were very beautiful. The bands were of a deep yellow, and four in number. Although our friend made no claims as to the fifth, the latter (or what looked like it) showed faintly. The bees from his breeding queens were as handsome as any I ever saw. He did not claim to have originated them, he having obtained them of a bee-keeper who is now out of the business. Mr. L. C. Hearn obtained one of these queens of Mr. Doolittle, and Mr. Timpe, in turn, of Mr. Hearn.

"Now," said Mr. Doolittle, "what next would you like most to see?"

"Suppose we look at some of the cells reared in upper stories. I have my camera here, and I should like to see and show to our readers whether you practice what you preach."

We selected cell-building colonies at random. In the first one we examined there were almost perfect rows of cells built on the artificial bases.

"Hold on a minute," I said, "and I will take a shot at it with my camera. There, I've got it."

"Why," said he, "as quick as that?"

"As quickly as you can snap your fingers," I replied.

So on we examined and photographed four or five other lots of cells; and as soon as I can I will present you with a fair sample of cell-building, in the shape of a half-tone engraving. And so all through, Doolittle practices what he preaches.

"You have your apiary in an orchard. I believe I like that better than grapevines."

"I don't like too much shade," said Mr. D. "I have noticed that those colonies under those very heavy shade-trees do not breed up as early, or do as well as those less shaded. There are two trees" (pointing to two very densely foliaged apple-trees) "that I shall have to cut out."

About this time Mrs. Doolittle desired him to get some vegetables from the garden. In the meantime I got off upon high ground and took views of the apiary, house, and general premises. The bee-cave had "caved" in recently, on account of the moisture from the bees rotting the boards. To prevent any recurrence of such a thing, Mr. D. proposes to use flagging for roof-boards, and then cover with dirt as before.

At dinner we had one of those unconventional bee-talks, in company with another bee-keeper whose name I do not now recall, but who happened to be visiting Mr. D. at the same time; and even after dinner there were so many things to talk about that it was hard to break away.

ON THE WHEEL AGAIN.

I oiled my bicycle, fastened the camera under the seat, and was soon on my way spinning past the shores of another beautiful lake, Otisco by name. This lake, like Skaneateles, is only a short distance from Mr. Doolittle's home. After leaving the lake I wended my way to Marcellus, the home of a once prominent bee-keeper. I continued on my journey, passing teams, until I found myself back in Syracuse. I made the distance in about 3 hours. I remained in the city over night. Next morning I was in doubt as to whether I should take the train or the wheel. My next run was to be a long one, and I had thought of taking the cars to save time. As I paid my bill at the hotel the clerk told me that

A STRIKE

on the New York Central R. R. had been inaugurated during the night, and that it was doubtful whether any trains would run during the day. As far as I was concerned, I did not care much. As the depot was near at hand I went over to satisfy my curiosity. Yes, the trains were stopped, and the agents would sell no tickets to would-be passengers. The strikers were scattered here and there. A company of militia were stationed at the depot. One passenger was cursing and swearing. He had got to make an appointment, and his anger knew no bounds.

"I wish I were fixed as you are," addressing me as he saw the bicycle.

I did not stop to swear and curse with him on the event, but started across the track, and, approaching one whom I took to be a striker, said:

"Are you going to pull out to-day?"

"Guess not, sir."

"Well," said I, "this train of mine hasn't struck yet, and I think I'll pull out;" and with this I started toward Starkville, thanking good fortune that "strikes" don't stop all the wheels of progress, for my wheel at that very moment was spinning along at a rapid rate. I continued until I had gone about 30 miles. I went a little out of my way on account of imperfect directions as to the road. It being Saturday, and as I could not reach Starkville, the home of Mr. Elwood, without riding on Sunday, I concluded to ride to the next station on the Central R. R., if I could get aboard of the cars. I found that there was a *chance* of getting on a train, and fortunately was able to get to Fort Plain toward evening. Starkville, I was told, was about 9 miles from Fort Plain. As I saw the hills, some of them fully a thousand feet high, my heart sank within me.

"It is late," I said to myself, "and to go over

an unknown and lonely road among those fearful hills is not inviting."

I buckled up my courage and started; and, to my surprise, in about an hour's time I was before the door of Mr. Elwood, the man who manages successfully over 1300 colonies. The hills were not as bad as they looked, and the road was not as lonely as it seemed.

AT P. H. ELWOOD'S.

I met with a hearty welcome from our big bee-keeper—large in several senses of the word. It was a little embarrassing on my part to come upon a family I had never seen, just at supper time, Saturday night; but when I went to the hotel at Starkville I was informed that Mr. Elwood had left word that I should come straight to his home, early or late; and accordingly I turned the wheel about, and was soon shooting down (or, rather, up) the road leading to the Elwoods. Their home is situated at the base of a range of hills (I wanted to call them mountains) of anywhere from 500 to 1000 feet above the valleys. To an Ohio boy this was all new, and I feasted my eyes on the scenery to my heart's content.

The next day was Sunday. I threw off my bicycle suit, and put on ordinary civilian's clothing. As my luggage on the wheel had to be compressed into a tight bundle, my clothing, I fancy, looked as if it had been through a—well, a crimping-machine or something of that sort. I was glad to go to church with the family; and it didn't matter at all, even if their denomination was different from mine. We all love the Lord, and we differ only in unimportant details as to beliefs. I enjoyed the services, and enjoyed, also, being in a God-fearing family for the Sabbath.

The scenery about Starkville, to an Ohio boy, is grand. While the country is not really mountainous it is very hilly. From many of the higher summits the whole Mohawk Valley spreads out before you, and off in the distance the dim outline of the Green Mountains can be seen.

Mr. Elwood kindly offered to take me around the country; and accordingly, the following Monday morning, one of the bee-wagons was hitched up, and we took a ride through the surrounding country, to take in some of the sights, and of course, in the course of the day, visit bee-yards. After driving to the top of one of those high hills and taking a general survey of the Mohawk Valley and adjacent country (a magnificent view, by the way), we visited a beautiful glen where there were some very curious rock formations—caves, waterfalls, and running springs. My Kodak was in readiness, and I took a number of shots (i. e., views). Vegetable matter that remains for a few years in the water of this glen petrifies. Among the specimens we selected were almost perfect petrified beach leaves, fragments of moss, etc. It was here first that I noticed what seemed to be true of all this section of country; namely, that the basswoods seemed to grow much more thrifflily than in Ohio. The leaves were enormously large. One we measured was 14 inches long, nor did this seem to be exceptional. At Mr. Doolittle's I noticed that the basswoods were of larger and better growth than with us, while on the sidehills of Starkville they were even more so. We started on our journey again, and were discussing as to whether the large-leaved basswoods were any better for honey than the smaller-leaved trees, when we drove up to the apiary of J. R. Tunnicliff, of Vanhornsville. Mr. T. owns some 400 colonies in three or four out-yards. He formerly used the ordinary hanging frame; used it faithfully for 50 years. Finally, in 1878, he adopted the closed-end frame, which he is still using. This frame, instead of *stand-*

ing upon a flat tin on the bottom of the hive, hangs in an ordinary wooden rabbit by means of a projecting headless wire nail jutting out from the top-bar. In other words, it is a hanging frame with closed-end bars. In connection he uses a wooden thumb-screw to reduce propolis accumulations. Mr. Tunnicliff was very enthusiastic over this arrangement. He declared it the best frame extant. As to the thumb-screw, he owed Mr. Heddon nothing for it, for he borrowed it of Mr. Manum, who had used it for many years before Heddon. He did not consider Mr. H. the first one to use closed-end frames in a tight-fitting box, for he had used them both in combination since 1878.

He had 400 colonies on these frames; and to show me how nicely they worked he handled several hives. They certainly did work nice, and, as Mr. T. said, he adopted them to save time in handling. The swinging frame took too much time in spacing and too much time all around. He was very enthusiastic over his hive. I took a Kodak view, and will perhaps give you a picture of it later.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

That art on which a thousand millions of men are dependent for their sustenance, and two hundred millions of men expend their daily toil, must be the most important of all—the parent and precursor of all other arts. In every country, then, and at every period, the investigation of the principles on which the rational practice of this art is founded ought to have commanded the principal attention of the greatest minds.

JAMES F. W. JOHNSTON.

THE VALUE OF STRAWBERRY-PLANTS TURNED UNDER.

On the 15th day of July we plowed under a bed of Sharpless strawberries that had borne an excellent crop of fruit, and had made a prodigious growth of foliage, runners, etc. Before turning them under, however, the ground was covered with a heavy coat of stable manure. With the manure and vines together, the plowman had considerable trouble in getting them all turned under nicely. In fact, a man had to follow (with a hoe or similar tool) to push the tangled vines from under the plow-beam. When it was all turned under, however, it was harrowed and rolled until fine and compact. Then a heavy coat of ashes from our steam-boilers was put on. These ashes were mostly from coal. Considerable basswood and pine, however, goes in with the coal. In order to get out the coarser portions we run it through a sieve, or riddle, such as is used for sifting sand or gravel. These ashes were put over the surface, from one to two inches deep, and harrowed lightly into the mellow surface soil. In this we sowed, the same day, radishes, lettuce, and turnips. Well, on the 15th day of August, just thirty days from the day the seeds were put in, beautiful radishes were ready for the market—in fact, the finest I ever saw. A nice shower fell soon after the seeds were sown, and the ashes had sufficient strength to destroy all insect enemies. Not even a flea beetle punctured the first leaves of the young radishes. They grew with a rich dark green, and a rapidity I never saw them grow with before. Neither have I ever had *good-sized* radishes fit for market in just thirty days, before. The varieties were Early Frame, Chartier, and Chinese Rose. The roots were beautiful, glossy, scarlet, straight, and true. In fact, we could easily have made a bunch of Chartiers equal to the colored plates sent out by the originator. The Early Frame may have been a little ahead of the Chartier; but three days later, the Chartiers

were much the larger and finer. In three days more (thirty-three in all) we had Early Bloomsdale turnips fit for the table. They, too, were wonderfully handsome, both radishes and turnips being crisp and sweet, far beyond the ordinary. The Grand Rapids lettuce was also fit to put on the market-wagon in thirty days. Of course, it did not make large heads in that time, but the leaves were as large as one's hand, and the plants made very fine basket lettuce. How much of this is due to the strawberry-plants and how much to the manure and how much to the ashes, we can not tell; but I think just about the combination was needed for the results noted. Mr. E. C. Green, of the Ohio Experiment Station, looked them over yesterday, and he said he had never seen anything to excel it in the way of a crop, in only thirty days. It should be remembered, that the ground was our best creek-bottom ground that had been enriched and worked over for the past four or five years.

Adjoining the above patch are some of our rows of strawberries which were also put out with the transplanting-tubes on the 15th of July. We did not think best, however, to put strawberries where strawberries had been the season before. These strawberry-plants, in 30 days have sent out runners and made little plants so that some of them are well enough rooted to bear removing from the parent plants; that is, by the aid of the tubes. Now, these few results give one a glimpse of what is possible in market-gardening, as well as in strawberry-raising. In forty days the radishes can easily be cleaned off, and another crop of something else can be turned off before winter. I am planning to transplant some of the Grand Rapids lettuce where the radishes are taken off, and thus get large heads before winter. With this high-pressure treatment, manuring, and tilth, there are quite a few crops that can be taken off the ground in forty or fifty days. *The energetic, go-ahead gardener, should have them right off promptly the very day the crops have arrived at their best, and more seeds or plants should take their place within one hour.* I know from experience that it is a very hard matter to push things like this; but I tell you, my friends, it pays.

On another piece of ground, when I saw the crop had almost reached maturity I allowed the weeds and purslain to grow for a while. It did not take the weeds more than a week or ten days to cover the ground with a wonderful growth while the crop was ripening; and just as soon as the crop was removed, weeds, tops, and all refuse matter were plowed under. In doing this, you want to be very careful that no seeds of purslain or of any thing else have become matured enough to grow; for if you do not, you will seed the ground with weeds. Keep your eye carefully on the weeds, and a good many times you can have a heavy growth to turn under, almost as well as not. Be careful, also, that this heavy growth does not take any thing from the maturing crop. A great many times it is better to wait a little until the crop is mature enough to be gathered, rather than to undertake to clean out the patch from weeds, etc., just before maturity. In fact, the nicest way in the world to make *sure* with purslain is to turn it under out of sight. Keep the cultivator going, however, so that no chance sprig stuck up through the dirt shall get on top of the ground and grow again. At this season of the year (Aug. 21), if any piece of ground, enriched as we have ours, is left idle for a week or ten days, the weeds will make their appearance. I would rather have the Acme cultivator go over the ground, say once in five or six days, if we can manage to have it.

GARDENING FOR SEPTEMBER.

During this month is the time to put out cabbage-seed for cold-frames. The Jersey Wakefield is the only kind we use for this purpose. Sow the seed in good rich soil, rather thinly, so as to get nice plants. When the leaves are as large, say, as a half-dollar, they are ready to transplant to cold-frames. I always enjoy this kind of gardening in the fall of the year. It looks nice to see these plants, so fruitful and bright and fresh, just when frost is ruining so many other things. If you have not put out your spinach yet for over winter, now is a good time to sow it. Corn salad can be put in at the same time, and both may be transplanted to cold-frames for use during winter. Now is a good time to sow Grand Rapids lettuce seed in view of having lettuce for Thanksgiving. In cities, nice crisp lettuce at Thanksgiving has got to be quite the fashion. Now, we are quite willing that people should follow the fashions just as far as they like, providing it runs into nice garden vegetables. Winter onions can be put out now tiptop. It is too late to sow turnips; but if you have ground in nice order, and turnips that need thinning out, you can get very nice ones by transplanting. One season we raised nearly a hundred bushels of turnips by transplanting them into cucumber ground after the frost had killed the cucumbers.

COLE'S NEW AGRICULTURE AT THE PRESENT TIME.

In excavating for our new building, it became necessary to go right down through the reservoirs of the new agriculture. Now, as you may know, I have been somewhat disappointed in the working of the reservoirs that cost so much money. A good many plants do not seem to do very much better over these reservoirs than anywhere else. But I have every year noticed this: After we get through with them, and they are abandoned on account of the lateness of the season, squash and melon vines are sure to spring up and grow with unusual luxuriance. This year a single squash-vine was growing with a rapidity, right under the glass, subject to the intense heat of the sun, that I rarely if ever have seen equaled. Although it had no water at all, and the top of the ground was intensely hot and dry, this vine scarcely wilted under the midday sun. Well, when we came to dig down through, although it was a very dry spell, we found the reservoir full of water, and the roots of the squash were down and spread out in the water. They had gone through at least 4 feet of earth, and then between the loose stones, to find water. This vine has now 13 great Boston Marrow squashes, and is still growing at a tremendous rate. A single banana muskmelon-vine near by has now covered perhaps an area of 10 feet square, and 7 great melons lie almost touching each other. When Father Cole spoke about having the reservoirs 6 feet deep, I thought he was down altogether too low; but I now discover it is not a bit too low for certain kinds of vegetation; and, furthermore, that at this depth the reservoirs in the clay soil will keep constantly filled with water; that is, if made with the overflow so as to keep just two feet of water in the bottom. It looks funny to see such rank vegetation growing up through a soil parched with intense heat, and as dry as dust.

GETTING STRAWBERRIES FROM RUNNERS BEFORE THEY ARE ROOTED.

One suggestion in respect to strawberry-plants. It is almost always so dry here that we can not get any plants, and I have wished there might be some way to do so. About two weeks

ago I cut a lot of runners and put them in a 4-inch soap-box near the well, and they are doing nicely. Why would not this be better for some of us than taking up the plant, as you suggested in Aug. 1 issue?

S. T. WALKER.

Forest Grove, Or., Aug. 11.

Friend W., your plan is already in use. By shading the ground and keeping it constantly wet, you can make the buds start before they show any root at all. This, however, requires considerable care and skill. After very small roots have formed, they may be put out in beds. By keeping them watered and shaded you will very soon get nice plants. You do not say that you watered them often, but we infer this from your expression of putting them near the well. The advantage over setting at once in the field is, you can put a good many plants in a small bed of very rich ground. After they get strong roots they can then be put out in the field.

STRAWBERRY-PLANTS FOR THE GARDEN: HOW CLOSE CAN THEY BE PUT?

I want to plant a small strawberry-patch for family use, about 30 by 40. How close can I plant them? I will fertilize them well. How will it do to mulch them with fine straw so deeply that not a weed can show its head?

L. A. DUGGAN.

Cuthbert, Ga., Aug. 21, 1890.

Terry, in his strawberry book, directs to thin the plants out in the fall, so that none of them shall be nearer to each other than 6 inches. From this I gather that, where ground is valuable, plants may be set in the fall as near as 6 inches, leaving a path one foot wide between beds 3 feet wide. When put so close, however, you would need to keep off every runner; then mulch the beds with cut straw, and the paths with long straw, and you will have pretty nearly the Terry system.

WINDMILLS AND TANKS: SOME SUGGESTIONS.

I am thinking of having a windmill and tank. I see from GLEANINGS that you have one of each, and I desire, if you please, to have your opinion as to the kind that is best; and is there any solution of the difficulty with wooden tanks, that, if they get even partly empty, in a short time the upper portion of the staves shrinks, and they leak when the water is pumped in again? Do you find that to be a drawback?

E. CALVERT.

Nashville, Tenn., Aug. 12.

Friend C., almost any of the windmills advertised in our agricultural papers, made by responsible men of good standing, will answer your purpose. The first one we bought was the Eureka, made by Smith & Woodward, Kalamazoo, Mich. Our larger one is the Eclipse, made by Fairbanks, Morse & Co., Cleveland, O. During a very dry spell this summer, when there were several days that no wind blew, our big tank did get a little dry around the top; and when a brisk wind came up suddenly I noticed the water coming through the cracks so as to run a small stream in several places. This was on the south side, where the sun struck the staves. As soon as the sun went down, however, the leaking was reduced to

drops, and by the next morning there was not a single drop. If the tub is properly put up, and the hoops drawn up with appropriate bolts, I think there will be no trouble. Don't drive the hoops to get them tight. Have them drawn up with good heavy bolts.

REPORTS ENCOURAGING.

120 LBS. FROM ONE COLONY.

I took off 120 lbs. of comb honey from one swarm last season up to August 31.
Winfred, S. Dak., July 22. J. W. CHAPIN.

A GOOD REPORT FROM CALIFORNIA.

The flow of honey is good here now. I get from 1000 to 1200 lbs. each week from 180 colonies. My crop will be from 8 to 10 tons this year.
Armona, Cal., Aug. 19. G. W. CAMP.

15,000 LBS. FROM 200 COLONIES.

I have taken this season from 200 stands, 15,000 lbs. honey, principally extracted.
Riverside, Cal., Aug. 19. L. SARLES.

FROM 39 TO 100, AND 3000 LBS. OF HONEY.

I have taken 3000 lbs. of extracted honey from my bees this year, all white clover—the nicest honey I ever got. I had 39 colonies, spring count; increased to 100.
Buffalo, N. Y., Aug. 2, 1890. FRANK M. JONES.

15,000 LBS. FROM 80 COLONIES.

I am working about 80 swarms for section honey, and it looks as if I would make pretty near 15,000 sections (1 lb). The bees are working well now, and have been working in the sections since the last of March. I am working about 15 swarms for extracting; they are doing well.
Acton, Cal., July 25. A. B. MELLE.

198 LBS. FROM ONE COLONY.

I began this spring with 15 swarms, and now have 30, and have taken nearly 2000 lbs. of honey up to the 9th inst. From one hive I have taken 198 lbs.; beginning to extract July 1, 60 lbs.; July 11, 40 lbs.; July 22, 33 lbs.; July 30, 37 lbs.; Aug. 9, 28 lbs.
Salt Lake City, Utah, Aug. 11. E. STEVENSON.

A GOOD REPORT FROM NEW JERSEY.

I have taken GLEANINGS since last February, and in that time I have not seen any thing in it from New Jersey. I see it stated in your last issue that the honey crop would be short. Well, I have some bees here. They are Italians and albinos, and I have one of Siberian. They have done very well so far this season. Some of my swarms have made over 100 lbs. this season, and none less than 50 lbs. We had no swarms in May this year in this part of the State, that I can hear of. Our white clover has been a good crop. It ran about six weeks, and now our fall flowers are coming out, with prospects of a fair crop. I have four swarms from three last year's colonies, and I had to use a bushel basket to take them from the tree in, and they filled it within two inches of full, which is the largest swarm in South Jersey, that I can hear of. One swarm of albinos swarmed twice; second swarm not so large as the first. My Italians have swarmed but once this season. Our bees in this section have been carrying pollen since last Christmas. The man I got my bees of has

been in the business, or had bees, for 16 years, and this year, he says, beats all he has seen for work. Bees do not swarm this year until they fill their hive, pound sections and all. We do not extract any honey here, but all pound sections is what we want. It brings a fair price. There are some black bees in this section, and we are trying to get rid of them, which will be a good thing if we succeed. There are not many here that keep more than ten colonies over winter, but I intend to see what can be done here with the little workers. I intend to have about 75 colonies, and then I can tell what there is in the business here. I think I am on the right road to make it pay here.
Vineland, N. J., Aug. 11. L. S. JONES.

REPORTS DISCOURAGING.

The honey crop is very short, one-fourth of what we had last year. *
Boscobel, Wis., Aug. 20, 1890. AUSTIN DEXTER.

If bees in our part of Nebraska get enough honey to winter on they and their owners will be in the biggest kind of luck. So far they have not got one quarter enough.
Dorchester, Neb., Aug. 17. C. F. THOMAS.

Honey crop a failure this year with us. I don't think we shall have over 500 lbs. of honey from 200 colonies, spring count.
Girard, Pa., Aug. 18, 1890. RANDALL & SEARES.

Our honey harvest this year so far is very poor. Basswood not a quarter of last year's crop. Clover is worse, if any thing. We have a very poor show in Fayette County, for 1890.
Randalia, Ia., Aug. 1, 1890. A. F. RANDALL.

The honey crop here is a complete failure. I shall not take 50 lbs. from 50 hives. My neighbor, who has 180 hives, has not taken a pound. What is the matter? Only 8 new swarms, and some of them weak.
Mona, Ia., Aug. 16, 1890. W. F. COBB.

No honey. New swarms would have starved if they had not been fed, and old ones made only about enough to carry them through the dry spell, which has recently closed by reason of plentiful rains. We had to feed cattle and horses through July and the fore part of August, just as we would in winter. Pastures and meadows are all burned up. We had very few swarms of bees, and scarcely any use for the goods we got of you this year. We lost many bees and plants which were growing finely when the dry weather set in.
Marceline, Mo., Aug. 21. W. H. COMBS.

Bees have done very poorly this year, but are working in buckwheat very fast now. I have one hive which I have extracted 104½ lbs. of honey from. This is more than double the quantity any other hive gave. These are pure Italians, dark leather-colored ones, very gentle. If this hive has not a honey queen, what one has? I have 43 hives of nice bees now. They have done very poorly in this locality this year; no swarming to speak of. I should no more think of going without GLEANINGS than I would without bees. As I am a young man, only 22, I have a great desire to settle in Colorado and run the business to its full capacity.
Manchester Bridge, N. Y., Aug. 11, 1890. EDGAR BRIGGS.

MYSELF AND MY NEIGHBORS.

I pray not that thou shouldest take them out of the world, but that thou shouldest keep them from the evil.—JOHN 17: 15.

While I write, an east and west railroad is building through our town; and yesterday 22 teams and 30 or 40 men were employed in making a cut through our own grounds. As this cut is from 2 to 12 feet in depth, it has required quite a force of men for about two weeks; and during these two weeks it has been my privilege to get pretty well acquainted with the average gang of railroad employers and employees, with their horse teams and mule teams, with their plows and scrapers, their pick-axes, and necessary adjuncts for camping out along the line. There is, I need not tell you, a general prejudice against this class of people. Many look down upon them; and perhaps a good many who take their ease and wear fine clothes say in their hearts as they look down upon them as they work in the deep cuts going through the hills, something as the Pharisee said in the parable: "God, I thank thee I am not as"—these men who have to work in the dirt to earn their daily bread. I know this is not the prevailing feeling in all hearts, for most good people look upon these friends as the pioneers, or those who go before and prepare the way for this great machinery of traffic and commerce. Great crowds of town people come down and gaze upon the ruin this railroad has made through my market-garden. The finest crop of bush lima beans is right in its pathway, and they would have been ready to pick in a week or ten days. But the men and teams could not wait. One of the finest patches of Ford's Early corn I have ever raised was also right in the pathway, and this would have been fit to pick in a week. But it had to go. When people expressed sympathy, and said it was too bad, I told them that we were glad to remove the garden-stuff for something so much better.

"Why, do you consider the railroad so much better than a garden?"

I have explained the matter so much that I fairly get tired of talking it over. To be sure, I consider the railroad better than a garden, or else I would not have given \$2500 to have them come through. Not only this, I gave them a strip of ground right through the center of our grounds, that was worth to me, under the circumstances, nearly if not quite \$2500 more. For six months back I have been expecting the work; and while I have been anxious to see them, there has been at the same time a feeling of dread. In some way, from what I had heard I had got an idea that the railroad-construction folks were a class of people without hearts or souls; but in some respects I have been agreeably disappointed. The chief engineer and the surveyors are very nice people indeed. In fact, some of them are boys who graduated from our own town. The chief engineer kindly consented to spare my carp-pond, although the right-of-way line went right through the middle of it; and they also arranged so as to save my fruit-trees. Not one had to be cut down or removed. In Ernest's absence I fear I neglected business somewhat, in order that I might improve the opportunity to get as well acquainted as possible with these people who carry the lines of progress in their hands. It was two weeks ago this morning (to-day is the 27th) since they commenced. I had just finished my breakfast. We had read our Bible-lesson, and I had prayed for grace and strength to take up whatever trials the day might bring. As I passed down the walk toward the factory I

knew there might be trials in store for me, greater than I expected, but I was glad that I did not know what they were. Before I reached the factory, however, one of the boys said, "The railroaders, with a great string of plows, scrapers, and other tools, are marching down to your garden."

I made a short cut, found the boss, and told him that, while every thing was at his disposal, I should be very glad if he would help me a little in protecting my crops, and also asked of him the privilege of removing the surface soil before they commenced their excavations. In a few minutes he surprised me by his hearty good will and emphatic directions to the teamsters.

"Why, Mr. Root, we will do every thing we can to avoid unnecessary damage to your stuff; and as to the surface soil, if you will stay here and boss it we will remove it for you."

From that moment pleasant relations have been kept up until the present time. May be you begin to wonder why I go into all these details about something comparatively unimportant. Perhaps you wonder what it has to do with the text. Just this: I knew by past experience, that, as soon as the men got well at work, cursing and swearing would be the order of the day, and I was not mistaken. I had resolved to be with the men in the outset, and get acquainted with as many of them as possible; and I wanted, if I could, to manage to remonstrate at the first oath that was uttered. I think I did, and for some time I was greatly encouraged to see how pleasantly they agreed with me, and gave me a sort of half promise not to swear, even if things did go wrong. It was not very long, however, before some pretty loud calls came from the factory and different parts of the grounds. I could not give my whole time to the new railroad. Before the men got thirsty I showed them my little spring, and got one of our boys to carry around water, with a dipper and pail. I lent them an ax and hatchet, a chain and a pick, and a shovel; and I kept men near by to assist them. I turned the cow and the pony outdoors, and let the men have the use of the cow-barn to stable their horses; and I succeeded without difficulty in winning their friendliness and good will. But, alas! it seemed like a drop in the bucket to attempt in my own feeble strength to teach men that a railroad could be built without cursing the God who made them. The scraper we brought on the grounds to remove the surface soil was rather small for a big team, and not exactly the right shape. The boss suggested right away that we could have one of his if we would have a little repairing done on it. Our blacksmith soon did the repairing, and, in fact, we have had quite a trade in repairing their tools for them right along. When I took their scraper I removed their clevis, as we had one of our own. That it might not annoy anybody, I hung it on a stake. Somebody else took it and laid it in one of the wagons. Finally somebody drove his team up to the scraper to hitch on. The clevis was missing. By the way, dear friends, have you ever had any experience in the amount of swearing that has been called forth by the loss of a clevis? We do not swear here on our own grounds, but I have been sorely vexed many times to find the team away off in the lots, the plow or harrow all in readiness, doubletrees on hand, and no clevis. On this account we have a lot of them hung up in a special place in the tool-house. Well, this man began to swear about the delay, and then he cursed the one who took the clevis away. By this time I was right before him, with my hat off.

"Look here, my dear friend, it was I who took that clevis. I hung it on that stake, in

plain sight, but somebody else has taken it since then. Now, please do not swear this bright beautiful morning. Before night we shall have many other trials and vexations. Wouldn't it be a great deal better to take every thing coolly and patiently? You know that the Bible says, "He that ruleth his own spirit is greater than he that taketh a city." He softened down, and laughed a little. By the time the man who put the clevis in the wagon had fetched it he was disarmed, and the victory was mine for the time being. Oh how I do love *such* victories! I like to come out ahead in any thing. When I used to fight by my own strength I would almost die rather than to be whipped, especially is I felt that my cause was right and just. But, how much better—how grand and glorious it is to conquer through the spirit of Christ Jesus*—to win by gentle words and by love; to catch a kindly and pleasant look from their countenances; to make them smile when they have been under the influences of an evil temper! How that little prayer wells up from my heart, "Lord, help! Lord, help!" as I think of these battles! By this time the boss was a very good friend of mine. He had not used a bad word in my presence, and I began to hope he would help me. But pretty soon I came up to him behind his back. He was swearing terribly at the awkwardness of some of the green teamsters. A crowd was around him, and there was a regular din—yelling at the horses, calling others to get out of the way, and cursing the stupidity of somebody else. It seemed almost out of place to interfere. But something had to be done, or I must give up the field. I hardly had time to breathe my little prayer. I did the best I could, but he did not take it very graciously. He muttered something about circumstances justifying extreme measures. I saw I had lost my hold on him. In the afternoon, however, he asked me who owned the lot adjoining, where they were to work next. I told him, and then he added:

"Mr. Root, I wish that lot belonged to *you*. In all my experience in my life of railroad building, I have never before found a man like you. I have never found a man before who seemed to think that we railroaders are human. Why, if I had you to deal with, a great part of my troubles would be nothing. You seemed glad to have us here in the first place; whereas everybody else regards us as enemies, and tries to beat us and come some game on us continually. Now, if there is any thing you want us to do, or any privilege we can grant you, just name it and we are at your service."

Pretty soon the contractor came around. He had a couple of ponies and a carriage. The boss and the contractor, of course, had quite a talk about the progress of the work—the prices they paid, etc. The contractor is a swearing man too, but his remarkable friendliness showed that the boss had made a good report in my behalf. I wanted a roadway on top of the heap of dirt, on their own ground. I asked if it would discommode them. The contractor replied, "Why, bless your heart, Mr. Root, why didn't you speak about it sooner? I would have had the men lay the dirt all in order for you. It is most entirely at your service; and when you want any privilege of the kind, do not be at all bashful—just talk right out, and give us a chance to show you that we appreciate the many kind favors you have shown us since we have come on to your grounds."

Now, friends, how much are such things worth from these officers and men in charge of our great railways? Don't you believe it will

really pay to invest a few dollars in showing that you are liberal-minded, and disposed to be brotherly and human? Before they came here, different ones told me that the gang would steal every thing in the neighborhood. They said our garden-stuff would be literally cleaned out. Well, just across from our spring is a row of extra-early watermelons. They were just getting ripe when the railroad came. I supposed that I should lose some if not all of them. By and by, when picking a lot for the market-wagon, my path lay right through these men at work. Shall I tempt them by letting them see the nice melons, and that they are already ripe? or shall I take them some round-about way to escape observation? The melons were pretty heavy, and I decided to wheel them right through the crowd. There was some joking as I passed by; but, dear friends, it really does my heart good to be able to say that not a thing in the shape of vegetables or eatables has been touched since these men came into our neighborhood. I have watched the melons there, and they have remained till fully ripe. One day the pony went to one of their wagons and ate up a peck of their potatoes that are worth \$1.20 a bushel. It was Sunday morning, and the campers had no means of buying any more. I told them to go into the garden right close to their camp and dig as many potatoes as the pony ate. But they declared it was their own carelessness, and I think not a potato was taken. Please do not think I am boasting of my skill in such matters. I boast not of myself, but of Christ Jesus. Paul says, "Yea, of myself I will not glory but in mine infirmities." I am glad to witness and testify to the power of the spirit of Christ Jesus, even amid the din and clamor of ungodly men.

I now want to speak of a subject that lies very close to my heart during the time of this matter of railroad-building: It is, cruelty to the mules and horses that construct our railways. And, dear friends, I have just made a discovery. The discovery is this: The key to most if not the cause of all the cruelty shown to horses lies in profanity. Profane swearing is at the root of the whole matter. One teamster gets mad and begins to curse his team. Another one takes it up, and by and by a dozen teamsters are striving to *outdo* each other in horrid oaths and curses. Then the whip begins to be used, and finally clubs; and these poor over-worked dumb friends of ours are urged beyond reason, when if the oaths and curses could have been stopped they would have worked reasonably and not beyond their strength. I wonder that those who own the teams do not see this. Now, I do not know how many of the readers of GLEANINGS are in the habit of swearing; but the idea may be new to you, that it costs you money every time you take God's name in vain. The money is a small part of what it costs, but it is a point where great corporations may be appealed to if no other. Where their pocket-books suffer, they are interested. I may as well tell you that I had to give up, mostly, trying to stop the swearing. When they had only four or five teams there was not any of it when I was in sight; but when it came to 20 or 30, where they were backed up by numbers, some of them seemed really to take a kind of pleasure in letting me know that I was whipped out. Oh, but I am not whipped out, dear friends! If you will not listen to my words, the great God above will hear my prayers. I *know* there is a time coming when railroads shall be built without swearing. Yes, I feel pretty sure there are godly contractors and bosses who are doing this very thing now; and I expect to hear some of the readers tell me of instances where it has been done. The horses would do more work,

* Not by might nor by power, but by my Spirit, saith the Lord of hosts.—ZECH. 4:6.

and the men would do more work, and God's blessing would follow in every department of railroad work if it does not follow now. Accidents and loss of life would be averted, and the peace of mind that follows a conscience at peace with its Maker would give an enjoyment that is worth more than all else in this world besides.*

On account of the Sunday-school picnic to be held to-day, our regular weekly Thursday evening meeting of the Endeavor society was changed to last evening. This appointment was made without considering that the last Wednesday evening of every month is the regular time for a union prayer-meeting of all the churches of Medina. It was not discovered until it was too late to have either of the appointments changed, and therefore part of us must go to one meeting and part to another. Toward the close of the Endeavor meeting, however, I suggested that we adjourn and all go over to the union prayer-meeting at the Disciple church. By the way, there is something fresh and reviving about the Disciples and the Disciple church. I have sometimes thought that their services were a little more in the line of every-day experiences than most of the other churches; and their hymns, some way, seem to wake one up, and give him a feeling of enthusiasm that he does not always find. You know, of course, without my telling you, that I am an earnest advocate of union meetings. "By this shall ye be known of all men that ye have love one to another." If our churches could not act in accordance with the above, what a sad thing it would be! So many were coming in toward the close of the meeting, the leader was again induced to mention the subject. It was something like this: The way to get good ourselves is to be busy doing good to others. I told the friends briefly of my experience in fighting profanity among the railroaders. The leader remarked that it was demoralizing, and almost dangerous, to hear such constant blasphemy. By the way, here is a point I have not emphasized. I know by experience that it is terribly demoralizing to be obliged to be present where such talk is going on. Why, I am really ashamed to confess that, after the conflicts I have been telling you of, sometimes, when tired out and sorely vexed at something, these foul words intrude themselves upon my thoughts, and I can hardly resist the temptation of thinking how some of those horrid oaths would fit under peculiarly trying circumstances. Unless you are fortified by constant and earnest prayer, and unless you fight with all your might and mental strength against it, your peace of mind will be in danger by simply being obliged to *hear* such blasphemy. Somebody suggested that our Medina boys, many of them unused to such talk, were obliged to hear it. And another suggested that the contagion had already got into our streets, and was possibly keeping away young converts from the regular appointed meetings. Then came up the subject of our text: Shall we be more pure in heart by keeping away from these places, and closing our ears to what is going on? Then suggestions came, that I should keep on laboring among these people, while others should stay away. The meeting was prolonged beyond the

usual closing hour. The real point of our text was the matter under discussion: Shall we go right into the clamor and turmoil and wickedness of the great business world, or shall we keep ourselves pure in heart by holding aloof? The answer that comes to me is something like this: The one who goes among these men and undertakes this work should be fortified and clad in the Christian armor, by an honest and sincere purpose to do these men good, and he should be fortified by earnest prayer in his closet by himself. He should go with the love of God filling his heart to overflowing; and he should pray meanwhile to be kept from Satan's strange power over those who even *hear* blasphemy against God. Unless one has this preparation he should keep away from scenes of this kind as much as possible. To go out of idle curiosity, and because one has heard of their goings-on, is dangerous; but to shirk duty, or to neglect *necessary business*, because we are thrown in contact with such scenes, would be folly. God's grace is amply sufficient to sustain his devoted followers through any such trial. I have told you of my many off-recurring temptations. Now, when I am engaged in revival work—when I am pleading for souls—then my heart is filled with that gift of the Holy Spirit which is so abundantly promised, and I am out of danger. Satan's old temptations and allurements sink into nothingness. And right here lies the secret of being delivered. I think, all at once from the great besetting sins. When the heart is full of love to Christ, Satan can find no lodging-place, and can make no headway. At just this point in our meeting, when I was praying that God might put into my heart some of these bright promises in the shape of a pertinent text, the organist, who is one of the leaders in the Endeavor society of the Disciple church, suggested the old familiar hymn,

"Am I a soldier of the cross?"

All at once it was taken up as the audience realized that here was the true solution of our discussion, and the plain and unmistakable hand of God pointing us to duty. As I look over the words I discover they were written by Dr. Isaac Watts in 1720. The tune, Mount Pisgah, was one I have heard my father sing over and over again, away back in the days of childhood. Memory came rushing fast as I listened. My poor old father, as I well remember, was sorely beset at times by Satan; and the reason why he loved these words was because they came to him bidding him gird up his loins and *bear* the cross. Here are the words; and I am also happy to be able to give you the "air" of the music. This was engraved specially for the occasion by one of our own people. The plan is one of his own originating:

Am I a soldier of the cross—
A follower of the Lamb,
And shall I fear to own his cause,
Or blush to speak his name?

Must I be carried to the skies
On flowery beds of ease,
While others fought to win the prize,
And sailed through bloody seas?

*The time has come sooner than I expected. Since the above was put in type, I am told that in the neighboring town of Lodi, this county, there is a gang of men and teams with a boss who is a Christian man. This boss told them, when they hired out, that there was to be absolutely no swearing. The gang is doing excellent work, and there has been no trouble in keeping out bad words entirely. They simply *started right*, with a Christian man to watch over them. May God be praised for it.

Are there no foes for me to face?
Must I not stem the flood?
Is this vile world a friend to grace,
To help me on to God?

Since I must fight if I would reign,
Increase my courage, Lord;
I'll bear the toil, endure the pain,
Supported by Thy word.

Now, if you have not learned this good old tune, please do so. If you are afraid to sing around other folks, go off in the lots and sing it by yourself until it brings the blessing to your heart, it has brought to mine. Then sing it to your friends. Do not be bashful or backward. Be a *brave* soldier. A simple little hymn like this, sung in your own way, and after your own fashion, will have a power you have no conception of, if you *sing* for *Christ Jesus*. Use the hymn to vary the usual plan of asking a blessing at the table. Get mamma to sing, and the little ones, and afterward explain to them what it means to be "a soldier of the cross, a follower of the Lamb." Tell them that good *soldiers* do not get mad and swear, nor quarrel, nor speak bad about their neighbors. Tell the boys that, if they want to be *manly*, they must get up and *work*, and not be *carried* about. Tell them that we want men now to *fight* for God and the *right*, as we *never* wanted them before. Tell them that, before they can be *bosses*, or have *command* anywhere, they must learn to rule their own spirits. Tell them this hymn was written more than 170 years ago by the same good man who composed the little verse commencing,

"How doth the little busy bee
Improve each shining hour!"

Tell them it is the hymn that is making Uncle Amos happy just now as he fights his battles and takes up his burdens. Tell the boys that Uncle Amos is praying for *them*. And that they may fight against this sin of our national profanity and irreverence to God, bid them be *brave* soldiers in the battle for the right, and tell them it was Christ Jesus who prayed, *not* that they should be taken out of the world, but that they should be kept from the evil.

TOBACCO COLUMN.

CONDITIONS UNDER WHICH WE GIVE SMOKERS TO PERSONS WHO STOP USING TOBACCO.

First, the candidate must be one of those who have given up tobacco in consequence of what he has seen and read in this department. Second, he promises to pay for the smoker should he ever resume the use of tobacco in any form, after receiving the smoker. Third, he must be a subscriber to GLEANINGS. Any subscriber may, however, have smokers sent to neighbors or personal acquaintances whom he has labored with on the matter of tobacco-using, providing he give us his pledge that, if the one who receives the smoker ever uses tobacco again, he (the subscriber) will pay for the smoker. The one who receives the smoker in this case need not be a subscriber to GLEANINGS, though we greatly prefer that he be one, because we think he would be strengthened by reading the testimonials from time to time in regard to this matter. The full name and address of every one who makes the promise must be furnished for publication.

HAS QUIT, AND EXPECTS TO STAY QUIT.

I believe I am entitled to one of your smokers, as I have used tobacco ever since I was eight years old. I was thirty-eight last Friday. I quit last January, and still expect to hold on.

Lewistown, Mo., July 28. H. MANSFELDER.

A NEW SUBSCRIBER QUILTS THE USE OF TOBACCO.

Mr. E. L. Yarbrough, of Buffalo, Dallas Co., Mo., desires you to send him GLEANINGS. He has abandoned the use of tobacco, and desires you to send him one Clark's smoker. He says he will pay for it if he ever uses the weed again.

Bolivar, Mo., May 19.

A. J. LOWER.

A SMOKER FOR A FRIEND.

I want you to send a smoker to me to give to brother Cook. He has quit the use of tobacco. He used it over 45 years. He is a good man, and class-leader too. I will pay if he begins using it again.

A. C. BURNAM.

Camden, N. Y., July 22.

A USER FOR 20 YEARS QUILTS.

In consequence of what I have seen and read in this department, I determined to stop using tobacco, which I have used for 20 years. I gratefully promise to pay for the smoker should I ever resume the use of tobacco in any form, after receiving the smoker.

Mikado, Mich., June 16. WM. R. CUMMINGS.

TWO SONS-IN-LAW WHO HAVE QUIT TOBACCO.

If you still give smokers to those who quit the use of tobacco you can send one each to Willie Godbold and Ralph Watson, both of Bowerton, Copiah County, Miss. They are both my sons-in-law; and if they ever use tobacco again I will pay for the smoker myself.

Wm. BOLES.

Bowerton, Miss., May 12.

SNUFF-DIPPING AMONG THE COLORED WOMEN.

I see in the Tobacco Column that a lady has quit smoking. I wish that by some means the ladies of this section could be induced to quit the very disgusting habit of snuff-dipping, which is so prevalent here among both white and black women, and thereby elevate them considerably in the estimation of many good people.

S. F. HERMAN.

Tuscaloosa, Ala., July 21.

Dear friend H., I have heard a good deal about the snuff-dipping habit; and I should be very glad indeed if something could be done to awaken and rouse up these sisters to a sense of what they are doing.

A SMOKER FOR A FATHER WHO HAS QUIT.

I am very glad that I am able to ask you for a smoker, as it is just what we need. My father has quit using tobacco, and says if he ever uses it again he will pay you for the smoker, and give you all our bees, which are fourteen nice colonies. I don't think you will get the bees. Please send it to John Woods, Ayer, Adams Co., Nebraska.

CORA WOODS.

Ayer, Neb., July 28.

THROWS THE OLD PIPE AWAY.

I will throw my old pipe away if you will send me a smoker, and I will not use the pipe again as long as my name is Mary. I can use rags cheaper than tobacco. If you ever hear of my using the pipe I will pay you for two smokers.

MRS. MARY A. MORROW.

Stromsburg, Polk Co., Neb., July 21.

We suppose, friend M., that by throwing away the old pipe you mean not to use tobacco in any form, and so we sent the smoker.

A SMOKER FOR AN ORPHAN BOY.

Three months ago I quit the use of tobacco through the influence of GLEANINGS. I do not need a smoker, as I have one; but if you wish to send one I will give it to an orphan boy to whom I have given a colony of bees; and if I ever resume the use of tobacco I will pay for the smoker.

J. B. ALEXANDER.

Hartford City, Ind., Aug. 7.

We take pleasure in sending the smoker for the orphan boy. We hope the boy will be informed of the circumstances, and never use tobacco himself.

EDITORIAL.

Thou therefore endure hardness, as a good soldier of Jesus Christ.—II. Tim. 2:3.

GLEANINGS' NEW DRESS.

For fear you might not have noticed it otherwise, we call attention to our brand-new type and our "bigger" and plainer letters. How do you like it?

PROFANITY.

ARE any of the readers of GLEANINGS railroad men? If so, do you have swearing at your daily work? and won't you lend a hand in this battle for the right?

ERNEST'S RETURN.

ERNEST drops in upon us just as we go to press, Sept. 1, and his father is very glad to see him, and quite willing to turn over to him his share of the editorial burdens.

THE HAVERLAND STRAWBERRY.

It has turned out somewhat as I expected. The tremendous demand for the Haverland plants has run almost every plant-grower into a corner. Our own stock is just exhausted, but we have found a place away off in New Jersey where we are told they can be bought. Before using them to fill orders, however, we shall set them in our plant-beds and wait until they have made good new roots, so your Haverlands may be delayed a couple of weeks. All the others will go as usual by the first mail. By the way, if any of the readers of GLEANINGS have any of the Haverlands for sale, will they please tell us how many they can furnish and at what price?

ADVERTISING THAT DID NOT PAY.

JUST two more report that their advertisement did not bring them a customer. One is H. L. Fisher, of Milford, Ind., who advertised three-frame nuclei for \$2.25 each, in May and June. He paid us \$3.50 for the advertisement; but as it brought him no customer we return him the money. The other was T. L. Thomson, of Blairsville, Pa. He advertised bees at \$4.00 per colony. As he made no sales we returned his \$1.20. There is another fact that begins to come out here, friends; and that is, that a new comer in the advertising field is not as likely to receive orders as somebody with whom the people have become somewhat acquainted; therefore there is an advantage, to a certain extent, in getting people familiar with your name and address.

THE STRAWBERRY, AND ITS ADAPTIBILITY FOR INTERESTING INVALIDS, AND KEEPING THEM IN THE OPEN AIR.

I do not know of any other plant that grows that one can work with, propagate, and see grow almost every month, when the ground is not frozen, like the strawberry. As cold weather comes on, confine your operations to a piece of ground protected by hills or buildings, or

both; and if you still wish to have them make runners and start plants, cover your bed, or a portion of it, with sash, when the frost is severe. Whenever the weather moderates so as to enable you to move the sash safely, do so; and whenever it rains, the sash are better off than on. By taking pains you can see them thrive almost all the year round, and you will have your reward in getting fruit a month earlier than those not protected. Of course, by the aid of artificial heat you can make them bear fruit in the winter time; but this is a more difficult operation.

QUEENLESS COLONIES IN SEPTEMBER.

THIS month and the next are the ones during which the average novice gets frightened because he can not find eggs or brood in the hive. In many localities the queens become so small and insignificant after they stop laying, that they are difficult to find; therefore the beginner sometimes even orders queens when every thing is all right and no queens are needed at all. Where honey is coming from fall pasturage, of course queens keep right on laying; and if you want your bees to raise brood this month, you can easily start them by daily feeding in small quantities. If the colonies are already populous, and have plenty of stores to winter them over, I do not believe it will pay to feed. If feeding is to be done, however, and no honey is coming in, I would do all the feeding during this present month, so that it may be well ripened and sealed up before cold weather comes on.

A VISIT FROM THE EDITOR OF THE AMERICAN BEE JOURNAL.

LAST Saturday morning, Aug. 23, while dictating matter for GLEANINGS, I was agreeably surprised to see the genial face of our co-worker, Mr. T. G. Newman, editor of the *American Bee Journal*. He remained with us only a few hours, but they were very pleasant hours, I assure you. We felt sorry to have our friend see so much disorder all about us, consequent upon the new railroad and the new building, but I presume he knows how to make allowances. It was a privilege to us all to have him occupy the time and take charge of our noon meeting; and, by the way, every time I think of it, it gives me a new thrill of joy when I think what a grand thing it is to have such pleasant and brotherly relations between the editors of at least two of our prominent bee-journals. By the way, why *shouldn't* editors visit each other, compare notes, and find out how and by what means they may *assist* each other? Just contrast for a moment the effect it would have on our nation to see such a feeling among the editors of our land, especially editors who conduct what might be called rival journals, and in fields perhaps already overworked. The Bible says, "Give, and it shall be given unto you;" but Satan whispers, "You want to be constantly on the lookout lest somebody overstep a little

on your domain;" and then he urges, "An eye for an eye, and a tooth for a tooth." O dear friends, shall we not hold fast to the teachings of the Bible? I hope every member of our establishment will remember that, inasmuch as friend Newman's voice has (at least *once*) been heard in prayer at our noonday service, his name, and that of the journal he represents, may for all time to come be held by us all in reverence and respect long after the present editors have been gathered to their eternal home.

SPECIAL NOTICES.

TERRY'S BOOK ON STRAWBERRIES.

We expect this to be ready to mail within three or four days. I think it will pay every strawberry-grower who has a bed of fifty plants or more. The price is 35 cts.; by mail, 40.

GRAND RAPIDS LETTUCE SEED WANTED.

If any of our readers have any, please tell us what you have and what you will take for it, or send what you have by mail, and we will pay you a good price for it.

COIN-SILVER WATCHES.

We have in stock three solid coin-silver watches, stem wind and set, open face, 14 size, with seven jewels, Waltham movement. We offer them post-paid and registered for \$10.00 each. They have a plain 2-oz. case, and we warrant for 30 days.

TIN-CASED GLASSED OIL-CANS.

We are able to offer a tin-cased glass oil-can, to hold a gallon, for 25c each, \$2.80 per box of 1 dozen. These have a spout with stopper, a 1-inch tin screw cap for filling, and a bale to carry by. They would make an excellent article to sell extracted honey in; for when empty it can be put to good use.

MISMATED QUEENS.

We have a few mismated queens in our apiary that we should like to dispose of during the next two weeks. They are good thrifty queens, reared from pure Italian mothers, but their progeny does not show the full markings of Italians, and hence they have to go for hybrids. Price 35c each, or 3 for \$1.00, while they last.

EXTRA WHITE COMB HONEY.

We have secured about two tons of very fine white comb honey from Matthias Schneider, Jr., of Iosco County, Mich. About half of it is in 12-lb., the rest is in 24-lb. glassed cases. The net weight is about 11 and 22 lbs. each. We offer this at the following prices: Less than ten 12-lb. or five 24-lb. cases, 18c per lb. From 10 to 50 of the 12-lb. and 5 to 25 24-lb., 17c per lb. Above this amount, 16 cents.

HENIS FRUIT-PRESS ADVANCED.

We regret to be obliged to withdraw the present low price on this very convenient and useful household utensil that has met with such favor. Since we first offered it for sale about a year and a half ago, we have sold nearly 10 gross. Recently a new firm has taken hold of it; and as it is patented, they, of course, control the price. Their first move is to advance the price to nearly double what it was. For the present the price will be 35c each; \$3.50 per dozen, or \$9.00 per box of 3 dozen.

SECOND-HAND TYPE FOR SALE.

Our readers will discover that this issue of GLEANINGS is in a new dress of type. Instead of setting part in nonpareil and part in brevier we have fallen in with the general custom, and use only one size, called minion, the articles being set solid, and the answers leaded. This leaves us with about 350 lbs. of second-hand brevier type in fairly good condition, which we offer for sale at 20c per lb., which is about

half the price of new type. If you don't want so much, write, naming the amount you can use, and we will make a price. We would much prefer to sell all in one lot, and that is why we make the price so low.

ARIZONA HONEY.

In the two weeks that have elapsed since the carload of honey reached us from Arizona we have disposed of all the comb honey and nearly a third of the extracted. After writing the notice for last issue we found that there was in the car some 2d and 3d grades that we can offer a little lower. We find, also, that nearly half the car is mesquite, which is lighter colored than the alfalfa, and a better flavor, if possible. We will mail samples of any kind or grade free on application. The price is 10c per lb. for one to five 60-lb. cans; 9c per lb. for from 3 to 10 cases of 2 cans each. In lots of 10 cases (1200 lbs.) or more, 8c per lb. Second grade, ½ cent per lb. less; 3d grade, 1 cent per lb. less than 1st grade. These 2d and 3d grades are not far below the first; but if you hesitate about buying, send for a sample which we will mail free on application.

THE ILLUSTRATED HOME JOURNAL.

This excellent monthly home magazine is published by Thos. G. Newman & Son, the editors of the *American Bee Journal*. It is a 32-page monthly, fully illustrated on nearly every page, and brimful of good, clean, interesting reading. Every number, we notice, also contains a song with music. It is a journal that ought to be in every home; and to make it still easier for you to place it there, the publishers have made us a proposition whereby we can club it with GLEANINGS one year for only \$1.35, and all new subscribers will receive the *Home Journal* for the rest of this year and all of 1891. Just think of it! If you subscribe now for GLEANINGS and the *Illustrated Home Journal*, sending \$1.35, you will receive fifteen numbers of the journal for the extra 35 cents—only a little over 2 cents each. This is a magnificent offer that many should accept. We will club the *American Bee Journal* along with the two for \$2.25.

KIND WORDS FROM OUR CUSTOMERS.

I received the 24 pumps all right from Canton, and they give satisfaction. JOHN A. SARVER.
Morton, Ill., Aug. 21.

PROMPTNESS IN SENDING QUEENS.

The dollar queen ordered about July 18th came in good condition, and two days sooner than I expected. I am highly pleased with her, and with your promptness. W. J. TAYLOR.
Palo, Linn Co., Iowa, July 24.

THE DAISY WHEELBARROW.

We received the wheelbarrow all right. It pleases the whole family very much. We have all taken a ride on it, even to Mrs. R., who enjoyed the wheelbarrow very much, but thought her horse a little frisky and unsteady. ARTHUR T. REED.
Oberlin, Ohio, July 29.

OUR METHOD OF SHIPPING STRAWBERRY-PLANTS.

The 200 Jessie and 50 Bubach plants are at hand, and set out. They could not come in a better shape. You certainly deserve every order sent you, if treated as mine was; all are living, and I am satisfied with your exertions to do as you would be done by. Thanks for the few extra ones. GEO. W. BALDWIN.
Forest City, Mo., Aug. 20.

PLEASED WITH OUR FOUNTAIN PEN.

I am just in receipt of the Bateman fountain pen, ordered of you, and I herewith wish to express my satisfaction in using it. Fountain pens have been very extensively advertised in the papers for some years past, but I thought I could not risk to invest in one, until I saw the one recommended by A. I. Root. Then I was sure I should find one just as represented, and I ordered one forthwith. I can say that I am well pleased with it so far, and have no doubt but that it will continue to do good service for a long time. SAMUEL E. MILLER.
Bluffton, Mo., July 26.

CONVENTION NOTICES.

The Southwestern Wisconsin Bee-keepers' Affiliated Association will meet Oct. 8, 1890, in Platteville, Wis., at the residence of E. France, to commence punctually at 10 A.M., sharp. There will be a large turnout of prominent bee-keepers of the State. A question-box, free to all, in which any subject you wish discussed can be presented and answered. Let every one be on hand and bring in his report for 1890, starting at spring count, or May 1. There will be blanks sent to each member for this purpose, in due time, by the secretary.

The following is the programme:
 Implements in Apiary, F. L. Snyder, Orion, Wisconsin.
 Artificial Swarming E. France, Platteville.
 Natural Swarming, G. O. Miller, Bo-cobel.
 Comb Foundation, Benj. E. Rice, Boscobel.
 Best Way for Hives to Face, B. Bartholomew, Boscobel.
 Races of Bees, N. E. France, Platteville.
 Wintering, In doors or Out, Charles Zelmer, Wauzeka.
 Feeding Bees, M. M. Rice, Boscobel.
 Location of Apiary, Court Main, Bo-cobel.
 Size of Hives, W. H. Pradeaux, Bloomington.
 Queen-raising, Introducing, etc., A. Arhus, Hurlbut's Corn's.
 Marketing Honey, H. Evans, Wauzeka.
 Help by our Society, National, State, and Local, N. E. France.
 Honey plants, J. W. Van Allen, Haney, Wis.
 How to Extract our Beeswax, Edwin Pike, Boscobel.
 Robbing—Cause and Cure, A. E. Collie, Mount Hope.
 N. B. The date of the above convention has been changed from the 1st to the 8th.
 Boscobel, Wis. BENJ. E. RICE, Sec'y.

The Capital City Bee-keepers' Association will meet at 10 A.M., Sept. 26, 1890, in the supervisor's room, at Springfield, Ill. All are invited, especially the ladies. C. E. Yocom, Sec'y.
 Sherman, Ill.

The next convention of the Turkey Hill Bee-keepers' Association will take place at the Turkey Hill Grange Hall, near Wilberman's Station, three miles southeast of Belleville, Ill., Oct. 30, 1890. All interested are invited. S. BRAETUGAM, Pres.
 Belleville, Ill., Sept. 9.

MICHIGAN STATE FAIR?

If so, please call at "**Bees & Honey Hall**," and examine the "Golden Italian Bees," on exhibition by **JACOB T. TIMPE**, of **Grand Ledge, Mich.** For prices on Queens see Oct. 1st. **GLEANINGS.** Don't forget to call while at the **FAIR.** I shall also have other races on exhibition. Don't fail to see them.

50 COLONIES OF BEES FOR SALE,

In ten-frame Langstroth hives, \$3 per colony. Have plenty of honey to winter on. Also a lot of bee-supplies. JOHN CROMBIE, Columbus, Wis.

FOR SALE.

Good farm, $\frac{1}{4}$ section, on ten years' time, 8% interest. Small payment of principal, one or two hundred dollars, and the 8% in advance yearly, or semi-annually. Has fine grove; 5 acres, 100 bearing apple-trees; small fruits; nice evergreens in yard; good well; house 14x26, with L 8x16; barn 16x32; board-roof granary 16x16; all fenced; 3 and 4 fields, all in cultivation; no waste land; 3 miles to P. O.; 1 mile to school; 3 miles to 5 churches. This is fine farm; price \$4000. Also 80 acres finely improved; all kinds of fruit for this latitude; for sale on as good terms; 80 rods to school; 1 $\frac{1}{2}$ miles to M. E. church; good locality; all American settlers; also good stock; horses, cattle, hogs, and 100 col's of bees in Simplicity hives. A fine chance for some one wanting to locate in Neb. Reason for selling: We wish to go to the Pacific coast. For further information, call on or address R. R. RYAN, Bradshaw, Neb.

HONEY COLUMN.

CITY MARKETS.

CINCINNATI.—Honey.—Honey of all kinds is scarce. There is almost no comb honey in our city. But, what is of greater importance, is, that we have hardly enough extracted honey to supply our manufacturing custom. The "hold on" doctrine is bad policy, as we are sure to be overstocked again about Christmas-time. Such has been the case generally, and is likely to repeat itself, in a great country like ours. Choice comb honey would bring 15¢@16 in the jobbing way. Extracted honey brings 5¢@8 on arrival.

Beeswax.—There is a good demand for beeswax, at 24¢@26 on arrival, for good to choice yellow.

Sept. 8.

CHAS. F. MUTH,
Cincinnati, Ohio.

ALBANY.—Honey.—We have received up to date, 251 cases of comb and 39 half-bbls. of extracted honey; nearly all of this is buckwheat of fine quality. Fancy clover seems to be very scarce. Trade opens up briskly at following prices: Clover, 16¢@18¢ per lb.; mixed, 15¢@14; buckwheat, 11¢@13. Extracted, 7¢@9.

CHAS. McCULLOCH & Co.,
339 Broadway, Albany, N. Y.

Sept. 12.

NEW YORK.—Honey.—Honey in the comb is very scarce so far, and new arrivals are sold as fast as they come in. Fancy white, 1 lb., 16½¢@18¢; fair, 14¢@16¢; dark and mixed, 12¢@14. We have received no 2-lb. combs as yet; these would bring about 2 cents less, according to grade. Extracted Florida honey, 7½¢@8¢; Common Southern, 6¢ per gal.; California, 6¼¢@7¢; Basswood and white clover, 7½¢@8¢. Demand is very good.—**Beeswax.** 27¢@28; stock small.

Sept. 11.

F. G. STROHMEYER & Co.,
New York City.

CHICAGO.—Honey.—Comb is now held firmly, and sales are being made at 17¢@18¢ for best grades of white. Up to this time there has not been more than the trade has taken from day to day, and as the weather is now cool an active trade will ensue. Extracted honey also sells well at 7¢@8¢ for barrels and cans. Mail orders are filled at above prices f. o. b., Chicago.

Sept. 10.

R. A. BURNETT,
161 So. Water St., Chicago, Ill.

ST. LOUIS.—Honey.—The demand is excellent for both comb and extracted, while the market is well supplied with the latter, the former is scarce. We quote: Choice white clover, comb, 13¢@14¢; inferior, 12¢@13. Extracted and strained, in barrels, 5¢@6; cans, 7½¢@8½. **Beeswax**, prime, 27.

Sept. 11.

D. G. TUTT GRG. Co.,
St. Louis, Mo.

KANSAS CITY.—Honey.—The demand for comb honey continues good; supply light. We quote: 1-lb., white comb, 15¢@16; dark, 13¢@14; 2-lb., white, 13¢@14; dark, 12¢@13. Extracted, white, 7¢; dark, 5¢@6. **Beeswax**, 2¢@25.

Sept. 5.

CLEMONS, MASON & Co.,
Kansas City, Mo.

NEW YORK.—Honey.—Honey is in excellent demand and finds quick sale at the following prices: Fancy white, 1 lb., 16½¢@18; 2 lb., 14¢@15; off grades, 1 lb., 13¢@15; 2 lbs., 12¢@13; buckwheat, 1 lb., 11¢@12; 2 lbs., 10¢@11. Extracted, basswood and clover, 8¢; buckwheat, 6¢; California, 6¼¢@7.

Sept. 12.

HILDRETH BROS. & SEGELKEN,
28 & 30 West Broadway, New York.

KANSAS CITY.—Honey.—Demand for comb is larger than receipts. We quote: 1-lb. white comb, 16¢; 2 lb., 14¢; 1-lb. dark comb, 13¢; 2-lb. dark comb, 12. Extracted, white, 7; dark, 5¢@6. No beeswax on the market.

Sept. 11.

HAMLIN & BEARSS,
514 Walnut St., Kansas City, Mo.

BOSTON.—Honey.—Honey is selling fairly well, from 16¢@18¢ for white clover 1-lb. comb. Extracted, 7½¢@9. No beeswax on hand.

Sept. 11.

BLAKE & RIPLEY,
Boston, Mass.

DETROIT.—Honey.—Comb honey is selling at 14¢@16¢; very little in the market. Extracted, 7¢@8¢. **Beeswax**, 26¢.

Bell Branch, Mich., Sept. 12.

M. H. HUNT.

FOR SALE.—1000 lbs. white-clover honey, in 1-lb. sections. Will pack in 25-lb. cases, crated to suit purchaser, and to go by freight. I want 18¢ for it here.
J. M. AKER, Smithville, Clay Co., Mo.

FOR SALE.—100 lbs. of white-clover honey, at 15¢ per lb., on board cars. LUCY NOYES, Geneva, N. Y.

WANTED.—A barrel of white-clover honey.
Address EDGAR BRIGGS,
Manchester Bridge, Dutchess Co., N. Y.

FOR SALE.—2000 pounds of very nice white-clover honey, in 60-lb. cans. H. VAN VRANKEN,
Union City, Branch Co., Mich.

FOR SALE.—5000 lbs. well-ripened extracted honey, in 60-lb. cans. C. H. STORDOCK, Durand, Ill. 18-23db

FOR SALE.—1200 lbs. extracted clover honey, in 60-lb. cans, at 10 cts. here.
R. H. BAILEY, Box 81, Ausable Forks, N. Y.

FOR SALE.—800 lbs. extracted clover honey at 9¢.
M. ISBELL, Norwich, Chenango Co., N. Y.

WANTED.—Honey, both comb and extracted. Give kind, quality, and price. Address
H. G. CAMP, Winona, Ohio.

WANTED.—To know who will furnish me about 700 lbs. buckwheat honey, f. o. b. State price and size of packages. Address
G. N. CORNELL,
91 West Main St., Battle Creek, Mich.

TO BEE-KEEPERS!

IN ADDITION to our New England **Honey Trade** we have leased a Store in New York City (in the best possible location to catch the Grocery Trade), and propose handling

COMB AND EXTRACTED HONEY

there. As we have been practical Bee-Keepers and have had some 12 years' experience in the Honey Trade (during which time we have handled MORE HONEY than any House in New England), we feel justified in saying that we understand the Honey Trade, and think we can handle your **Surplus Honey** to the very best advantage.

We shall endeavor to make Quick Sales at the **very highest prices**, and by making prompt returns we hope to merit your patronage. Advances made when requested. Stencils furnished — also printed instructions for Packing and Shipping, giving valuable information gained by our experience in Shipping Honey by the Ton and in Carload lots.

Correspondence, Visits, and Consignments Solicited. Address

F. I. SAGE & SON,

TOO CLOSE SPACING, ETC.

GETTING WAX OUT OF EXTRACTORS.

On page 589, friend Root, you say you don't bother to re-melt the wax to get it out of the extractor-pan. Then your pan must be different from mine. Mine has a screw-cap that would not allow the cake of wax to come out. I wish it weren't there. But the wax I have been getting would have to be re-melted any way, because there is so much bee-glue mixed all through it. When the mass that is put in to be melted is half bee-glue, a good share of this latter runs through the strainer, and I don't know any way to prevent it; for when hot enough it is just like molasses. Fortunately it takes more heat to melt bee-glue than to melt wax. So when the pan is full as it can conveniently be, I set it in the oven of the cook-stove till the wax is melted, then pour it off, leaving the bee-glue to be scraped out of the pan.

FRED C. SMITH'S TOP-BARS—SEE PAGE 602.

They are $\frac{3}{8}$ wide, with $\frac{5}{16}$ between them. That makes $1\frac{1}{8}$ from center to center. Isn't there danger of running close spacing to extremes? The harm done by it may not always be seen. In cool weather the spacing may be so close that a sufficient mass of bees can not get between the combs to get up the requisite heat. This might continue for years, and not be noticed. But there is one thing that can be noticed, if one takes the pains to look. I have had some closer spacing within the last two years than I have ever had before. Now and then I have found a comb, on one side of which there was no brood throughout a large part of it. It was worker comb, black with age, the cells empty, and every thing appeared right about it, only the queen laid no eggs in it. I think the only trouble was that there was not room enough between the combs. The spacing of top-bars was no closer than for other combs—why should there be any difference? Well,

the spacing of the top-bars doesn't tell the whole story. Suppose you examine one of your hives with common hanging frames. First see that the spacing of the top-bars is perfect, each space just exactly like the others. Now tip up the hive and look at the bottom-bars. Don't you see how irregular the spacing is? Some spaces are two or three times as large as others. But there is another reason for irregularity. Even with wired frames, the septum of the comb is not always exactly in the center. Suppose one comb has the septum $\frac{1}{8}$ of an inch to the right of the center, and the adjoining comb has its septum $\frac{1}{8}$ to the left of the center. That may make the distance between the comb surfaces $\frac{1}{4}$ of an inch less than the average. In friend Smith's case, that would make the combs less than one inch from center to center. The only thing, then, for the bees to do is to leave one surface of comb unused, cutting down the cells as much as may be necessary. Of course, I have taken an extreme case, but I think it shows that we would better space too wide than too close.

QUEEN-EXCLUDING ZINC FOR NON-SWARMING EXTRACTING.

On page 630, F. H. Cyrenius says: "For non-swarming extracting, when the hive is full of brood, and honey begins to come, place a set of empty combs or foundation below with the queen, the brood above, and the zinc board between, and they will roll in the honey if it is to be had, and will fill the upper story as the brood hatches, and the outside combs below." I tried several precisely as directed above. In each case the queen stopped laying. In all but one case I put a frame of brood below after waiting two or three days, and then the queen went to laying. In the remaining case the queen was put below the excluder May 24, and left till June 3, when I found only eggs below, showing that the queen stopped laying at least a week. Now, I'm not sure that it is always bad to have the queen stop laying: I only want

to call attention to the fact, that, if you want to make sure of her laying right on, you must give her one frame of brood as encouragement. Possibly bees do not always act as mine did, but I suspect they generally do.

GETTING BEES TO EMPTY SECTIONS.

On page 638, E. D. Howell asks how to get the bees to carry the honey from partly filled sections to the body of the hive when they need it for winter stores. If they need it for winter stores they will carry it down if the sections are left on the hive; but sometimes they make very slow work of it. To hasten matters, if your hives admit of it put the super of sections under the hive. If the work doesn't then go fast enough, put the super of sections on the stand, on top of it an empty super, and on top of this the hive. Look out for robbing. Leave no entrance at the bottom of the super, and, if necessary, contract the entrance in some way. If robbers are troublesome, make the change in the evening. If you merely want the sections cleaned, without caring what colonies get the honey, put several supers in a pile away from the hives, covering up securely, leaving room for only one bee to enter at a time.

Marengo, Ill.

C. C. MILLER.

It must be, friend M., that our pan is different from yours. When we first began making solar extractors we made the sides perpendicular; but friend Green wrote us that we ought to make them sloping, so the blocks of wax would drop out when the pan was inverted, and we have since done so. It is possible that you have one of our first extractors; and in that case the wax might not come out without melting. As the wax comes from our solar extractors, it is a nice clear yellow, and would be entirely fit for market were it not for its shape. But, about that propolis, it must be that you have more than we.—Yes, I think there is danger of carrying close spacing too far; but instead of having frames further apart, why not use fixed distances, and then the bottoms of the frames will be spaced as accurately as the tops? It would have done you good to see some nice combs at Elwood's and other places where they use fixed distances.

E. R.

BI-SULPHIDE OF CARBON FOR WAX-LARVÆ.

USEFUL ITEMS FROM PROF. COOK.

Can you inform me, through GLEANINGS, as to the advisability of using bi-sulphide of carbon for destroying the wax-worms in empty combs? Is it safe to use it for the same purpose with comb honey? Sulphur I dislike to use with comb honey, as it is so easy to use too much and injure the color and flavor.

ARTHUR C. MILLER.

Providence, R. I., Aug. 27.

Prof. Cook replies:

In reply to Arthur C. Miller, Providence, R. I., regarding the use of bi-sulphide of carbon to destroy the bee-moth larvæ, I can say unhesitatingly that it will kill them, and, unless turned on the comb, could harm nothing. It might dissolve the combs if turned on them, but would not harm them otherwise. If the combs are put into a tight box or barrel, the liquid turned in, it could be turned against the side of the box or barrel, so as not to touch the combs, and the box at once covered tightly by the use of

oil cloth or other close fabric, the insects will speedily succumb. In case of comb honey it would be entirely safe if used in the same way. I do not suppose it would do any harm to turn it on to the combs. I will at once try it and report. The only danger in the use of this liquid is its explosive character. Of course, safety demands caution that no fire be brought near. The vapor is very inflammable, and, when mixed with the air, quite explosive, so we must keep all fire, like lighted matches, cigars, etc., away till the vapors have escaped. The odor is so marked that it is easy to tell when it has all escaped. This volatilizes so entirely that we can turn it on flour and no harm will follow. It passes wholly off. Bought at wholesale it is very cheap, and I see no reason why it may not be used very satisfactorily by the bee-keeper.

THE TEXAS COW-KILLER.

W. O. Victor, Wharton, Tex., sends a cow-killer. This is illustrated in my Bee-Keepers' Guide, and has been frequently described in GLEANINGS. It looks like an ant, except it is hairy, and is a rich carmine red, bounded with black. It is wingless, though a female, hence the generic name, *Mutilla*. It has a very powerful sting, as Mr. V. says he knows from experience. Will he tell us how its sting compares with that of the bee? I suppose it is much more painful. The insect is a fine one, though badly crushed in the mail. If put in a box or hollow stick with cotton it would have come in good shape. It is not found north.

THE GRAPE SPHINX AND ITS PARASITE.

Mrs. J. R. Beatty, Massillon, O., requests me to explain the relation between a large green caterpillar found on "ivy"—doubtless Virginia creeper—that grows on her porch, and several white egg-shaped masses which stand side by side on its back. These large, fine, green larvæ develop into a handsome moth, the grape sphinx. This so-called worm resembles in form and color the "tomato sphinx" larva, with which all are familiar. This larva is lighter green; the caudal horn is green instead of black; the spots marking the spiracles or breathing-mouths along the side of the body are much more obscure; and instead of several oblique yellowish stripes along the sides there is a nearly white stripe. These larvæ are very common this year, both on the ampelopsis—Virginia creeper—and also on the grape. I think Bertie has had nearly twenty of these in a breeding-cage on our porch during the past few weeks. Indeed, did not nature lay a heavy hand on these larvæ they would make sorry work with the plants which they infest.

Now to answer Mrs. B.'s question regarding the egg-shaped bodies on the back of this sphinx caterpillar: These are the cocoons of minute braconid flies—*Apanteles congregatus*, Say. These little flies lay their eggs in the sphinx larvæ. The minute parasites which hatch from these eggs feast on the caterpillar as it feasts on the grape or ampelopsis leaves. With so many little mouths feeding on its vitals, who can doubt but this larva is a believer in "internal improvement"? The braconid larvæ kill the sphinx larvæ, save our vines for us, and come forth to spin their cocoons on the back of their victim. Thus he bears about on his back his own destroyers, and the parents of other parasites that will do a like good work in the future.

When the box arrived, the little flies had come forth from the cocoons, much as a queen-bee comes from the cell. It is to be hoped that Mrs. B. and the children of many bee-keepers will put these larvæ in glass cans with cloth tied on for a cover. Feed them grape leaves, and so rear the parasites or the beautiful moths. The moths will not come forth from the pupa

till next summer. Bertie expects to rear several moths, as he thinks he has several larvae that are not parasitized.

A. J. Cook.

Agricultural College, Mich.

A MINNESOTA APIARY.

BEES AND GARDENING.

I send you a photo of our Dovetailed hive apiary. Although the hives are not all dovetailed, they will be another season. There are 56 colonies in all—30 in Dovetailed hives. The artist took the picture during our swarming season. You will see my swarming conveniences, from a barrel of water to Manum's device. Your humble servant sits in his old army-chair at the table, in the act of putting foundation into sections. His better half is at his right, and their family of five to the left, near the hammock and swing. Our help (brother and sister) are in front of the house. There are two rows of raspberry-bushes, and some rows of potatoes in the foreground, not shown. The for-

account of its small size, strong and close-fitting joints, just adapted to this cold climate. If the hive were any larger I could not have handled it without loss.

I have a very fine bee-escape in my cellar, with screen windows. The filled supers are taken from hive to cellar near a window. The bees all leave the same night. The wax and propolis are so hard in the morning that you can scarcely take out section-holders and sections. The honey is not allowed to remain in the cellar any length of time, but is taken to a warm room to be more thoroughly ripened. If the editor of GLEANINGS, or any of his assistants (they would all be welcomed) should visit us another fall, they will find a much larger house, better adapted to the wants of a growing family.

WIDE AND THICK TOP-BARS A SUCCESS IN THE DOVETAILED HIVE.

July 19th I took off the first case of honey from the Dovetailed hive with thick and wide top-bars. There was no sign of burr-combs between the top-bars of the frames or on the bottom of the super. The honey was taken

A DOVETAILED HIVE-APIARY.

mer, when grown, will make a nice windbreak for the apiary, which is located in a grove on the edge of the prairie. At the right is my main garden, extending down to a small lake. At the rear of the house is a belt of timber more than a mile in width, bordering one of the largest and most beautiful lakes in the county, called Green Lake, from the color of its waters. This section of Minnesota is called the "Park Region," as it is interspersed with lakes, groves, and prairie. Probably no finer section of farming land is in the Northwest. Our soil is a rich gravel loam, with subsoil of clay. We can cultivate our gardens after heavy rains.

Our garden (for 12 years adjoining the beeyard) has been cultivated by horses on two sides of the apiary since its location, and they have never been stung. Of course, our bees (hybrids and blacks) are handled with care, and honey is never left around to start robbing. We should all feel it a great hardship to be deprived of our bees, and we should as soon think of being without milk as honey. I was first led into keeping bees through failing health. It has been a pleasant occupation for mind and body, and has paid better for the amount of capital invested than any other investment on the farm. I am following diversified farming—raising horses, cattle, growing grain, and a small dairy. I adopted the Dovetailed hive on

from a strong colony of bees in the middle of a heavy flow of basswood. There was no sagging of the top-bars. Last year was my first experience with burr-combs and slatted honey-boards (having used previously a closed-top frame), and I hope it will be my last.

N. P. ASPINWALL.

Harrison, Minn., July 21, 1890.

JULY 15TH GLEANINGS.

ITEMS FROM EXPERIENCE. FROM AN A B C SCHOLAR.

Mr. Root:—The contents of No. 14 of GLEANINGS having been devoured with my usual keen appetite for good things, I am now ready to offer my little mite toward spreading another feast. If my offering is palatable, give it a place on the table; but if not, cast it aside. First, in behalf of the A B C class, I wish to say that we are thankful that our reverend friend Stenger is not the editor of GLEANINGS. From what he says about foolish questions, I fear many of us would fare but indifferently at his hands. Yet we heartily agree with all he has to say on the subject, and are doubly thankful that we have such patient instructors as we find in both the Roots. Much as I detest

the filthy, sinful habit of tobacco-using, I can not indorse Bro. Stenger's last sentence: "Tobacco does even *more* harm than the heavy drinks." The tobacco vice is money, and possibly health, wasted on filth and general nastiness, and is, in the writer's judgment, positively sinful. But alcoholism is reason dethroned, morals debauched, health destroyed, hope blasted, money wasted, and souls damned. Tobacco robs home of cleanliness, and gives to a wife foul lips to kiss, while drink robs home of happiness, and for kisses gives blows and dire distress.

COVERS FOR CHAFF HIVES.

I want to tell you how I have made some covers for chaff hives that suit me exactly—hand-some, light, true, and tight. I found the comb, or two-piece cover, almost sure to warp, so that moths, robbers, etc., could readily crawl under. After considerable study I decided on the following: After the hive was furnished ready for cover I fitted and nailed strips on to the hive-roof so as to raise the upper story or surplus chamber one inch at the back, and three inches at the front, with sides sloping from three inches to one inch, thus giving two inches pitch for roof.

I made my roof of very narrow half-inch matched linn, by nailing same to $\frac{3}{4}$ -inch-square cleats, so that these cleats would fit neatly over the end-pieces, front and back, mentioned above. I also nailed similar cleats under the edges so as to fit down over sloping sides, thus forming a complete cap-cover. I leaded the matched joints, and painted both sides. I bored a hole in the three-inch piece under the front end of the cover, and tacked a wire net inside and outside for ventilator: and now I think I have a perfect cover.

KEENEY'S METHOD OF WIRING A SUCCESS.

I have tried Keeney's plan of wiring, with Ernest's suggestion of wire-nail hooks, and I regard it as just the thing. I filled some of these frames with strips of four-inch section foundation by turning the edge of the foundation over the comb-guide so as to cover the guides on both sides. These have been built out beautifully, and I think it would take considerable pounding to knock out the combs, and I feel sure the top-bars will never sag.

SKUNKS AND BEES.

Your answer to E. W. Easter, as to why the bees dwindle, is most probably correct; but had I asked you a similar question a few weeks ago, and had added the fact that they had a prolific queen, what would have been your answer? In fact, I have had quite a remarkable case of dwindling, which I fancy might have puzzled some of the veterans had they not, like myself, by accident discovered the cause. And now I want to say to the A B C class, and may be the veterans might do well to lend an ear, beware of *skunk* dwindling. These little varmints nearly skunked me out of one good strong colony, and seriously damaged several others; and had I not tumbled on to their depredations early in the game, I don't know what the result would have been.

I happened to use some coal ashes to level up a place for a hive; and shortly after, and while the ashes were still fresh, I discovered one morning after a rain, that the alighting-board was smeared over with wet ashes, and the ashes in front trampled down in a suspicious manner. Having gone carefully through my A B C, I at once recalled the few lines on skunks as among the enemies of bees. I kept watching for further evidence of their mischief, but saw nothing for several weeks, and had almost forgotten the matter. But while I was absent from home, Mrs. B. discovered one of our best

colonies dwindling rapidly from day to day; and recalling what I had said of skunks, she set our 12-year-old boy to watch at night; and, sure enough, he discovered not *one* but *two* of the rascals at their mischief. He was afraid to tackle them, and went to a neighbor's for a gun, but when he came back they had gone, or at least he could not find them. Next night they put in an appearance, and he tackled one with a stick; but after giving it a beating it got a shot at him, and hit him in the eyes, blinding him so he could not see. Still he beat at it until his stick broke, and the rascal escaped. The bold little marauders returned the following night. I, having that day returned home, set poison for them. My son has seen one of them once since, but we have no further evidence of their rascality. Now, bear in mind there was absolutely no odor to betray their presence until my son struck one of them. May it not be possible that their mischief is much more common than has ever been suspected?

Wheelerburgh, O., Aug. 4. J. M. BROWN.

Friend B., it is no doubt true that tobacco does not do the harm directly that alcohol does; but it is the opinion of many of our best and wisest teachers and professors of colleges, ministers of the gospel, etc., that, indirectly, tobacco does more harm than alcohol. It paves the way for the stronger stimulants. An intemperate man always uses tobacco, and I feel sure that it is quite likely that, had he never used tobacco, he would never have had a craving for a stronger stimulant. Dr. Kellogg says that the young man who coolly and deliberately takes hold of a stimulant that he has no craving for, will, without question, have little scruple in gratifying himself in something that his lower nature *does* crave. If our boys can be kept from using tobacco, they can likely be kept from intemperance, licentiousness, and all these other low passions.

BEE-ESCAPES.

THE DIBBERN AND WRIGHT ESCAPES A SUCCESS.

Some two months ago I received your shipment of Dibbern horizontal bee-escapes, and prior to that I had made several after the pattern illustrated on page 280, GLEANINGS (W. W. Wright's). Both have given entire satisfaction in practical application on the Dovetailed hive. Usually from 10 to 25 bees can be found in the super after its removal. Once I met with an utter failure; but on examination I found the queen in the super with the bees. So far I have found the best results with an eight-cone Wright escape. I have tried them in various ways, and sometimes have taken off the super in three hours, and sometimes have left it on two days.

In practice I have had the best results by placing the escape over a super of empty sections, so that the bees are not forced down into the hive nor compelled to lose any time. The conditions under which these tests have been made are peculiar. There is here *no fluctuation* in the flow of nectar. Through a term of years I have found that I can depend on a moderate honey-flow every day for five months.

S. W. SHERFEY.

Mesilla, New Mexico, Sept. 8.

THE T SUPER.

DR. MILLER OVERCOMES SOME OF ITS OBJECTIONS.

I shall be rather surprised if, within a few years, I do not find something I like better than the T super. As yet, however, I have not seen it. In the meantime I am doing all I can to learn how to overcome the objections to it. I suspect that some who have tried it have not known how to use it properly. Certainly I have learned something in this direction since first using it. A very fair summing-up of the disadvantages of the T super may be found on page 69 of the latest edition of the A B C. They are given under three heads; and a fourth, until lately, would have been added by me. I will speak of it again. Under the first head, friend Root says: "Open-side sections, which of late (1889) are growing in favor, can not be used in it." If I remember rightly I have seen it stated that of late the call for open-side sections has not been large, and I have had the impression that they were rather growing out of favor. How is it now, friend Root? In any case, I think there are some who, like myself, have tried and rejected the open-side sections, and for such this first objection to the T super does not hold.

A B C gives objection 2: "As the upright of the T takes about $\frac{1}{16}$ of an inch, it leaves spaces between the rows of sections, which the bees are inclined to fill with propolis. . . . One-piece sections have a tendency to be diamond-shaped; . . . they come out of the super a little bit out of square." This is putting it very mildly. Instead of $\frac{1}{16}$, the upright of my T tins is $\frac{1}{8}$. The super is $17\frac{1}{2}$ long, inside measure, and four of the $4\frac{1}{4}$ sections measure 17 inches, leaving $\frac{3}{4}$ space for play. And the sections do play. They slouch around in all sorts of shapes, leaving spaces anywhere from nothing to $\frac{3}{8}$ of an inch for the bees to fill with glue. Often the side of a section for more than two-thirds of its length will be entirely covered with propolis, some of it a fourth of an inch thick. I am happy to say that I have entirely overcome this objection. In getting ready for the harvest of 1890, I ordered of A. I. Root separator stuff cut 12 inches by $\frac{1}{4}$, enough to have three pieces for each super. This, of course, meant stuff $\frac{1}{16}$ thick. When it came it was 12 by $\frac{1}{4}$, but the thickness varied, averaging about $\frac{1}{8}$ of an inch. I was taken aback. It would leave no play whatever to get in these three sticks, and it would be simply impossible to get them in. But in this, as in many another case, I found myself mistaken. Although it made a tight fit, there was no great trouble in getting them in. You understand that, after the supers were filled with sections, and the separators all in, these little sticks were pushed down across the supers in the spaces left between the rows of sections, so that four sections, $4\frac{1}{4}$ each, and three sticks each $\frac{1}{8}$ in thickness, just exactly filled the super.

I do not know of any new thing I have tried this year that has pleased me as much as these little sticks. Every section is held perfectly true and square, having no chance to be otherwise, unless so much out of square that one end of the section rises up, which it would do just as much in a Moore crate. The sides of the sections are, of course, entirely clean. Not a bee has a chance to get at them.

In using these little sticks I found another advantage not to be despised. Before I tried them I thought it would be harder to draw out a single section held in place by the sticks, and harder to put it back. To my surprise I found it somewhat easier to draw out, and a great

deal easier to put in. There is less surface friction. In putting in a single section without the sticks, the section generally strikes on the upright of the T, and you can't push it to one side enough to slide it down. The two sticks make a play-space of $\frac{1}{4}$ inch all the way from the sticks to the T, allowing you to move the bottom of the section back and forth to strike the right spot.

I don't know by what sort of bungling friend Root sent sticks $\frac{1}{8}$ thick when I asked for separator stuff, but I'm sure I don't want them any less.

The third objection the A B C makes to the T super is, that it is not an easy matter to make the central and outside rows change places. Friend Root, would you make such change if it were easy? Is there any advantage in it? C. C. MILLER.

Marango, Ill., Aug. 25.

Yes, friend M., open-side sections, in the early part of 1889, seemed to be growing in favor, but, for some reason or other, have been growing less and less popular. We made special automatic machinery, so that we could make them at the same price as the regular two-beeway section; but now there is scarcely a call for them. The first objection, then, does not bear very hard against the T super. Objection No. 2 can be obviated by the little sticks, but it seems to me as if they would be a good deal of a nuisance. We have three loose T tins, and then, after that, three more sticks—six pieces besides the T-super shell itself to hold the separators and sections. I do not know, friend M., unless it was the great rush during the past season, how we came to give you separator stuff thicker than you ordered. I am very glad now if our oversight was a blessing in disguise. The last objection still holds. On my trip among the York State bee-keepers I found that those extensive bee-keepers, many of them, prefer some arrangement whereby they can shift the outside row of sections to the inside, and *vice versa*. That is why, friend M., I like section-holders. By the way, Elwood uses almost identically our section-holder; or perhaps, rather, I should say, we are using his. See Notes of Travel elsewhere. Hetherington uses the T-super arrangement.

IN-AND-IN BREEDING.

IS IT INJURIOUS?

A correspondent writes, that in his apiary of 75 colonies he has two colonies which cap their honey very white, with very even combs. He says that he would like to propagate these bees for this special quality, and desires to know whether the rearing of queens from one and drones from the other will do, as the two queens are sisters. He thinks that such in-and-in breeding might tend to make the future generations of his bees weakly. If we were sure that both parentages were alike, there might be some chance of making our bees weak by in-and-in breeding; but as it is almost certain that they are not, such breeding as he proposes could not be directly in-and-in breeding. While I do not indorse the Dzierzon the-

ory to its fullest extent, yet it is sufficiently accurate so that, practically speaking, the drones and queens from any mother-queen can not be brother and sister. Now, if our correspondent raises his queens and drones from the same mother, the queens can do no more than mate with a half-brother, unless this mother-queen mated with a drone from her own mother. In this case he would get only three-fourths blood, unless the grandmother to our young queen mated with a drone produced by her mother. Should such a thing as this happen, he would get only seven-eighths blood by breeding drones and queens from the same mother. Here is a point not generally understood by many of our bee-keepers, and one which shows the wisdom of the Creator of the bee. To return to the original question:

Suppose he rears his queens from one queen and the drones from the other as he proposes. It is no way likely that both of the queens mated with brother-drones; hence the young queen will be only half-blood relation to the sister of the mother-queen; and as the drones will be only half - blood relation to the mother of the queens, he can not possibly get a relation nearer than one-fourth. Hence it will be seen that, with no control of the drone, our improving our bees in any one special direction must be only a slow affair at the best, and one in which in-and-in breeding has no very important bearing. Now, suppose we have it all arranged as we wish, and on July 1st we commence to rear our queens, we having plenty of drones flying from the aunt of these young queens. And to make matters more sure, suppose that we have drone-traps on each hive in the apiary, except the one we have selected for our drones; what proportion of these young queens will mate with the drones we wish them to? Well, that will depend upon how near there are other bees to our apiary. If, as we find it usually, not one queen in five will mate the desired drones at this time of year. It is a rare thing to find an apiary where there are not some bees kept within three or four miles of it, or where there is not some tree in the woods that contains bees. This tree, or one of the hives kept by most bee-keepers, will furnish more drones than the breeder will get from his selected colony, as a rule; for colonies that have no attention given them are very prolific in drones. I am satisfied that all the drones of one vicinity have a certain place where they congregate, and that the queens go to this congregating-place when they fly out, which results, as I said before, in the chances being against queens mating as the breeder wishes. To illustrate:

In 1872, Italian drones were reared for the first time as near as three miles of my apiary. That season I purchased an Italian queen, but she gave no drones, as I did not get her till July. There were none but black bees about me up to this time, and no queens had ever shown any yellow in their offspring. This year, about one queen in eight gave workers that were hybrids, many of them being finely marked Italians. With this positive proof before me, that bees mix to a large extent when separated three miles, I can hardly feel pleasant when reading the statement of some, that half a mile in distance is enough to keep two races of bees pure. I find that this congregating of drones and queens occurs only during our summer months, with perhaps a part of September. As the weather becomes uncertain, the loud humming that has been heard on all pleasant days, at a certain place, between the hours of noon and three o'clock in the afternoon, ceases. I find that from then out I am much more sure of having my queens mated with the desired

drones than at any other time of the year, unless it be in early spring.

Again, at this season of the year nearly all the drones are killed off except those especially kept by the apiarist, so that, when it is possible to rear good queens at this season of the year, and we have a few pleasant days, in-and-in breeding can be more nearly accomplished than at any other time; yet, as I have shown above, not enough so to cause our bees to deteriorate very much in some time. If, after we find all drones killed off except those we have preserved, we go to the hive having our drones, some rather cool cloudy day when the hives can be kept open as long as we choose without danger of chilling the bees, and without danger from robbers, and pick out all the inferior drones as to size, color, or any other imperfection, and kill them, we shall then have something from which we can improve our stock in the way we are desirous of doing, and still have it becoming more valuable along other lines as well.

I admit that this is a sort of rambling talk, but perhaps the reader may find something of interest in it after the chaff has been sifted out.

G. M. DOOLITTLE.

Borodino, N. Y., Sept. 2, 1890.

You are doubtless right, friend D. Queens are very apt to be fertilized at a distance from home, and they no doubt seek a place where drones congregate. An interesting point comes up here. There are a good many now who are breeding untested queens for market. Those who have just begun in a new locality will probably find that a very large percentage of their queens will turn out to be hybrids. It takes years for a locality within three or four miles of the breeding-yards to become so thoroughly Italianized that nine-tenths of the untested queens reared and sold will prove to be purely mated. There will be bee-trees containing blacks or hybrids, and it will be a long time before these will be Italianized by the slow process of superseding old queens or the infusion of new Italian blood in the progeny of young queens.

BEES TAXABLE PROPERTY,

AND FOR GOOD REASONS.

A. I. Root.—Your name has become quite familiar to me through the agricultural press. It seems that your interests must be varied. I have a friend who frequently sends to you for bee-supplies. I see notices of your operations as a farmer, and, if I mistake not, a few years ago I saw an item telling of your experiments with A. N. Cole's sub-aqueous culture, in which I have taken a deep interest. Have you given to the public the results of those last experiments?

What could have suggested the discussion of the advisability of taxing bees, now going on in your columns? Is some bee-owner trying to escape bearing his just share of the burdens of government? The theory of the law in this State is, that every thing that can be converted into property, and that may be made useful to man, shall bear its proportion of tax. There are no exceptions. Every pig, chicken, horse, or ox, must be listed; every bushel of grain, every pound of wool, every yard of cloth, every wagon, cart, watch, or clock must be put down in the list at its true market value, and to its

truth you make oath. Why exempt bees? As valuable and useful as they are, they are certainly not more useful than horses and cattle, than corn and wheat, than apples and grapes. If bees are to be exempted, why not these? I will go further: If bees are to be exempted, why not exempt the houses and barns, and all other improvements that are the products of human labor? If you were to exempt these last from taxes, would not more and better houses be built? Would not better improvements be put on farms and lands? Certainly there would, by the same logic by which you show that freedom from taxation would improve the bee-industry.

Let us look at it first from a selfish point of view, from that of the bee culturist. Would the prosperity of the farmer, the merchant, or manufacturer, which would certainly result from freeing them from the burdens of taxation, injure the bee-man? I think not. Their improved condition would enable them to patronize the bee-man more liberally. The demand for honey would be greater, and, of course, prices would be higher unless the supply were greatly increased.

It seems to me that the bee-man should look at this question with a broader view than that of his mere personal interest. He should surrender the whole question of the taxation of personal property, if he claims exemption for his own business. If he insists on the taxation of personal property at all, he must be willing to patriotically bear an equal share of the burdens of taxation.

W. O. FOLEY.

Greensburg, Ind., Aug. 23.

We think you are right, friend F. Bees are property, like any thing else, and we do not see any reason why a bee-keeper should not bear his just share of the general expenses of the county and State affairs. And now we think it is best to drop the discussion here, for there will be two sides to the question until the law settles the matter.

FOUL BROOD.

AN ACT FOR THE SUPPRESSION OF THE DISEASE IN CANADA.

By this mail I send you a copy of our foul-brood pamphlet, in the form of an official government bulletin, which has just been issued under the direction of our Minister of Agriculture, and a copy supplied to every bee-keeper in this province whose name and address could be obtained. An edition of from seven to eight thousand has been printed, besides a German edition for the use and benefit of bee-keepers who can not read English.

From this pamphlet you will see what we are doing here in Ontario toward the suppression and extermination of that curse of the bee-yard, foul brood. In six short months after taking the initiative at our last annual meeting we have a government "Act for the Suppression of Foul Brood among Bees," which is, perhaps, the best of its kind in the world, and have already got in under its provisions a great deal of effective work. I trust our American brethren of the bee-craft may follow our example, and earnestly set about the eradication of foul brood from their country. As there is considerable interchange of bees and honey between the two countries, we are concerned in your action in these premises, as you are in ours.

Our foul-brood inspector has been busy in his official capacity during the past two months, having overhauled hundreds of diseased colonies in different sections of the province, and

applied remedial measures which are eminently successful.

While the act under which we are working authorizes us to destroy by fire all colonies with the malignant form of the disease, and although some of the apiaries dealt with were fairly rotten with the disease, our inspector has not yet found it necessary to cremate a single colony. We cure the worst cases and forms of the disease, and we wish all concerned to know it. One indisputable and clear fact is worth a large number of theories. Under these circumstances I may be pardoned for suggesting to our American friends the wisdom and propriety of now ceasing to discuss unprofitable hypotheses, and settling down to work on this foul-brood question. Foul brood can be cured, and cured every time, by a simple hygienic process, and without the aid of the chemist, the druggist, or the drug doctor. This is a broad and radical statement, but I make it deliberately and advisedly. In the bulletin referred to, you will see how we do it. Two methods are given there—one by D. A. Jones and another by Wm. McEvoy, our inspector. Substantially they are the same, being both predicated on the same principle. We have faith in our works, and we wish to inspire you with the same faith. "Go thou and do likewise."

Without undue presumption I would further suggest that GLEANINGS summarize the two plans of treatment of foul brood given in our pamphlet, for the benefit of such of its readers as may need the information; or, what may be better still, give the matter in full. The bulletin, as you will see, also includes the *act*, which would also, I doubt not, be interesting and profitable reading for them.

ALLEN PRINGLE, Pres. O. B. K. A.
Selby, Ont., Aug. 5.

We have been informed that foul brood is very much more prevalent in Canada than in the United States, and hence an act for its suppression became almost a matter of necessity. Our Canadian brethren are to be congratulated for the vigorous manner in which they have taken hold of the matter. The "Bulletin" referred to above is before us. It is issued by the Ontario Department of Agriculture, and is, therefore, under the official insignia of the government of Ontario. The method of cure is, briefly, the starvation plan—the one, and only one, in our large experience, which we practiced with success; and the same has been incorporated in the last three or four editions of our *A B C of Bee Culture*. As it has been already given three or four times in these pages, it will not be necessary to repeat it again. The act for the suppression of the disease, briefly stated, is as follows:

The Ontario Bee-keepers' Association shall appoint an inspector and a sub-inspector, whose term of office shall be for one year. The inspector shall visit any locality in the province of Ontario, whenever directed by the President of the O. B. K. A. If he finds the apiary diseased, he shall order the infected hives and colonies to be destroyed by fire, or be treated by any method which the inspector may deem reliable or safe. Any owner of diseased colonies who shall sell diseased bees, shall, on conviction, be fined not less than \$50 nor more than \$100, or be imprisoned for any term not exceeding two months. If any owner shall refuse to allow the inspector to examine his apiary, or should such owner refuse to destroy any infected bees and appurtenances, he shall be liable to a fine of \$50 for the first offense, and \$100 for the second and each subsequent offense. The O. B. K. A. shall include in its annual report to the Minister of

Agriculture a statement of the inspector's work—number of colonies destroyed, etc.

For a complete copy of the act, apply to A. Blue, Toronto, Ontario. In another part of the bulletin, before discussing the method of cure, the cause of the disease is assigned to rotten or decaying brood, either from chilling or otherwise. In fact, the inspector, Mr. McEvoy, lays particular stress on this. We can not believe that foul brood starts without at least the germs of that disease. We have had a great many colonies in the apiary during the spring that had more or less chilled brood; but they never developed into any thing serious. Rotten brood may be a favorable medium for the growth of the *germs* if they are *already* present in the hives; but we can not think that this is of itself a *cause*. We may have the very best of land in which to grow corn; but corn will not grow unless there is first the seed. Further on in the bulletin we notice that there is a difference of opinion as to whether it is necessary to scald or disinfect diseased hives. We have tested that matter very thoroughly in our apiary. At one time we took twenty that had contained diseased bees, and put in healthy bees on frames of foundation. In every one of the twenty, foul brood broke out in from one to two months. At the same time we tried another lot of about an equal number, putting diseased bees on frames of foundation in hives that had been scalded, and a complete and permanent cure was effected in every one. Where hives had not been scalded long enough, the disease reappeared. We are very certain that Mr. McEvoy is wrong in thinking or advocating that diseased hives taken from diseased colonies are harmless; and we are equally sure that Mr. Jones is right in advocating that all such should be disinfected. If the bee-keepers of Ontario get the impression that hives from foul-broody colonies will not again transmit the disease, they will find, sooner or later, that they are making a most fearful blunder. As Mr. Pringle says, it is better to be on the safe side; for, "if the disease might in one case in a hundred be so propagated, the precaution of disinfection would be amply justified." We are glad to notice that the act itself directs that all hives and appurtenances in contact with foul brood shall be disinfected.

THE HOFFMAN FRAME.

A GOOD TESTIMONIAL FOR IT.

I should like to add my experience with the Hoffman frame. Some 12 years ago I was keeping bees near Baptisttown, N. J., and used a frame $\frac{7}{8} \times \frac{3}{4}$. I bought some bees of A. W. Lundy, living at Frenchtown, N. J., the pioneer bee-keeper of that section, I think, in 1878. The frames had a bottom-bar $\frac{1}{2} \times \frac{3}{4}$. I liked them so well after using, that I made mine $\frac{3}{4} \times \frac{3}{4}$. Soon after, Mr. Lundy made the ends of his frames $1\frac{1}{2}$ or $1\frac{3}{4}$ wide, the top $\frac{3}{4}$ wide, for $\frac{3}{4}$ of an inch, with a top-bar $\frac{3}{4} \times \frac{1}{2}$. The bottom of

the end-bar was cut down to $\frac{3}{8}$, like a Hoffman end-bar. About this time I adopted the Hoffman frame, made with a bottom-bar $\frac{5}{16} \times \frac{3}{4}$, and used them until I came to Florida, in 1885.

Some of the advantages are, moving from one to any number of frames to one side to get at a central frame by using a screw-driver as a lever; can pick up one to four or five frames, and carry where you wish, and no danger of mashing bees. In moving a hive with empty frames, foundation, or, when full of bees, the frames do not slide together, nor do the bottoms strike, nor are they ever *stuck* together. The bees are more easily confined at the top of the hive, as the ends of the top-bars are close fitting, and in the winter and spring the top corners of the frames, the hardest part of a hive to protect, forming virtually a dead-air space, while the narrow bottom-bar allows dead bees and debris of all kinds to drop to the bottom-board. To be used without reversing for box honey, I believe it has no superior. I forgot to say, that, with a narrow bottom-bar, combs are built clear down to the bar.

The bees built very few mounds from the bottom-board. The top-bars form practically a queen-excluding honey-board, and much less comb is built between frames and sections than where plain $\frac{3}{4}$ top-bars are used, and much less propolis is used.

When used with a dummy at the side of the hive there is no difficulty in getting the first frame out; or where side boxing is practiced. Many other advantages that have been mentioned I need not recall; but for certain localities, methods of management, and certain individuals, I think they are the best. JNO. B. CASE.

Port Orange, Fla., Aug. 22, 1890.

BEES ATTACKED AND DRIVEN OUT BY RED ANTS.

THE RED ANTS OF TEXAS.

On the 22d of July, bees commenced robbing a hive that was strong but queenless, early in the morning. I closed the entrance to about $\frac{1}{2}$ inch, and left to go to my work. I got back about 11 o'clock, and found the combs broken down and honey running about the ground. I had to open the entrance to give more ventilation, and by night they were completely whipped out. The next day we had a heavy storm. The wind blew two 12-inch boards that were fastened together in among my hives, spread the contents of four all over my ground, and broke the cover and side of another. It may have been some minutes before I discovered the mishap, and it was raining and blowing so hard that it was a hard matter to stand under it, and some little time before I could get the hives set up and the frames of lower and upper stories in place. Very few frames had broken combs, but most of the bees lay drenched on the ground. Upon examination I found two queens missing. Next evening I was called up. Bees were swarming. I found a colony of red ants had left their nest and invaded one of the hives that had lost its queen. There were ten ants to one bee, I should think. The bees had no chance. The hive was full of ants, covered with them. The ground for yards around was covered. Thousands had wings and thousands without. Their sting is worse than a bee-sting. They were evidently mad, and to go among them was to have them all over you. The hole into their nest was close to the hive. Several times I had buried a bottle and caught a lot of the ants, trying to destroy them. It seemed a premeditated plan of retaliation on the bees. The bees went into a tree.

I hived them several times, but they refused to stay anywhere but in the tree. I placed a box over them, and after several days of wind and rain they went up into it. I smeared them well with honey, and emptied them into a hive that was rather weak. Next morning they all lay dead outside. My experience this year has been, out of seven swarms hived on foundation, empty combs, or empty frames, 4 went off; out of 22 hived with a frame of brood, none went off.

Is the following, reason or instinct? A large spider was chasing a small one in a bush. A line of web ran from the bush to the top of a fence. The little one ran up the line and the big one after him. When about half way, the little one was nearly caught, and he turned round and bit the line in two. He fell to the fence, and the big one back into the bush.

Lytle, Texas, Aug. 8. GEO. E. HAILES.

Friend H., you surprise me by saying that the sting of the red ant is worse than that of a bee. They must be much larger, I presume, than any ants we have here. Perhaps Prof. Cook can tell us something about it. Why didn't you pour coal oil on the ant colony? Surely that would have "fixed" them.—Your testimony in regard to preventing new swarms from absconding, just about accords with our experience.—About the spiders, I should not call it either reason or instinct, but only an accident. I can hardly believe the small spider "figured out" that cutting the rope would give him the advantage.

RAMBLE NO. 28.

IN STEUBEN COUNTY.

We found, after a few days' trial, that the county-house of Steuben Co. is a model institution. Mr. Eli Carrington, the keeper, has held his position for eighteen years. The inmates are well fed and comfortably clothed, and their spiritual wants are attended to by hearing the gospel preached nearly every Sabbath.

It is well known that temperance advocates lay much stress upon the poverty-producing qualities of a too free use of the bottle. In our investigations in this home of the poor we found substantial proofs of the statements. Mr. C. informed us that fully two-thirds of the inmates were brought there either directly or indirectly by the use of intoxicants. Here is a man with a leg off, caused by injury by ears, while drunk; here is an excellent carpenter, able to earn the highest wages in his trade—is handy at repairing or making articles at this place; but just as soon as he earns money it goes for drink, and he becomes a most degraded drunkard. Here is a young man, strong, healthy, and capable of earning good wages on a farm, and making himself an influence among his fellow-men; but the earning of a little money allows him to invest in degradation. So we might enumerate other instances of wasted lives. But, oh! the saddest scene of all is a death and burial of the poor—no friends to shed a sympathizing tear. A few men deposit the body in its final resting-place, where no mark is put up to indicate that a human being is there buried. A minister preaches a short sermon to the living inmates, and they are soon forgotten. The sad lessons learned from these paupers, and the cause which led to their misery, will ever be remembered by the Rambler.

Bath has several fine churches. We attended the Baptist and Presbyterian. In the latter we

found a very large Sunday-school, and what is reported to be the largest young men's Bible-class in the State of New York. There were over 150 in the class, taught by the editor of the leading paper of Bath. We found one of the secrets of his success in the *personal* work he devoted to the cause. His religion seemed to be the every-day kind, and the seasonable word was spoken at all times and occasions. Would that Sunday-school teachers would go and do likewise all over our land!

With the county-house as a center we directed our rambles in various directions. One very interesting point visited was Hammondsport, on Keuka Lake, the very center of the great grape-growing industry of the State. The climate near these lakes in Central New York seems to be adapted to small-fruit culture, and especially grapes; but on the shores of Lake Keuka seems to be the natural home of this rich fruit, and thousands of acres are under cultivation. Thousands of tons of grapes are shipped in baskets and crates to be consumed according to nature's way; but tons are also used in the manufacture of the various wines known to the trade. The Pleasant Valley Wine Co. is the largest concern of the kind, and uses tons of grapes. The process in its first stages is much like making cider from apples. A similar grater is used, and for expressing the juice a Boomer & Boschert press is used. The wine is then kept for a time in large tanks. It finally is put into bottles, and stored in a dark cellar. Candles were lighted, and we passed between long rows of bottles piled up like stovewood, several thousand bottles in a pile. After some weeks they are taken from this pile and inserted, cork down, in long racks, where they remain a long time, but being often disturbed, and put back again. In hot weather the men who handle the bottles have to wear wire masks over their heads, for there is danger of being severely cut by bursting bottles. Our guide had his hand bandaged from such a mishap; and though it was cool weather at the time of our visit, we could often hear the pop of a bursting bottle. Our guide informed us that about

RACKS OF WINE-BOTTLES.

thirty per cent of the wine and bottles was thus wasted. Coming to the upper regions again, we were shown machinery for washing, for filling, corking, tin-foiling, and labeling the bottles, until finally they looked so enticing the Rambler thought of getting one into his pocket; but a reconsideration prevented. We imagined how we should like to see the honey business just boom in this way, and see all of this work done in a factory for preparing honey for market; but this, perhaps, is an idle dream, for honey does not pander to the perverted taste and passions of men.

Our guide finally led us into a little carpeted room with easy-chairs and a round table, and invited us to sit down. Several bottles and wine-glasses were procured from the next room, and said he, "Gentlemen, what will you take?" My traveling companion said he had no choice. The Rambler said his choice was not to drink. A bottle of champagne was, however, opened, and the glasses filled. Ah! it appeared to be good wine; it

worked aright in the glass, sparkling like so many rays of light. It looked very fascinating. Our traveling companion used up two glasses. Our guide also helped himself, but the Ram-

RESTING-ROOM, PLEASANT VALLEY WINE CO.

bler's glass was not emptied. We learned that there was much drunkenness about Hammondsport, and we were pointed to a farm on the hillside where a man had such conscientious scruples about the manufacture of wine from grapes that he pulled up his vines and devoted the land to other purposes. That the moral conscience of our whole land were educated up to this point is the earnest prayer of the

RAMBLER.

BEE BOTANY.

PROF. COOK NAMES A FEW HONEY-PLANTS IN MISSOURI.

Prof. Cook:—I send you by this mail a number of flowers which I should like to have you name through GLEANINGS, if not imposing too much on good nature. No. 1 is a weed that grows mostly on uncultivated or abandoned fields, and along roadsides, to a height of four to six feet. The flowers commenced opening the last week, and will continue until frost. I feel certain that it furnishes the greater part of our autumn honey here. Friend Root says it is a species of boneset.

No. 2 is a kind of creeping vine, not a native here. It blooms from about July 15 until frost, and the bees work on it almost continually when the weather is suitable. It is very hardy and thrifty. The roots seem to go a long distance under ground, and, where exposed, they sprout out and grow into vines. No. 3, I suppose, is a species of mint. It does not seem to be indigenous here, as I know of only one small patch. The bees work very vigorously on it.

No. 4, I suppose, is the heartsease that in some localities produces the principal crop of autumn honey, and was described some months ago by you. The bees work on it here occasionally, but it does not amount to much in the way of producing honey. We have two or three more closely allied to it, which grow in profusion on low ground, but bees seem to pay little attention to them.

Nos. 5 and 6 are not honey-plants, but furnish an almost unlimited amount of forage for cattle on the islands in the Missouri River. No. 5 is known here as sticktight or beggar-lice; it grows to a height of from 3 to 5 feet. On the sample I send there are flowers and seed not fully developed. When ripe, any one who walks through them, if he has on woolen pants, will ever afterward remember them.

No. 6 is known here as peavine, but it seems to be more of a bean. The pod, when ripe, has a peculiar habit of suddenly flying open, each side curling up, throwing the beans in every

direction. As you will see, I have just taken pieces of the vine. S. E. MILLER.

Bluffton, Mo., Aug. 26.

Prof. Cook forwarded the above to us, and replies:

No. 1 is *Eupatorium serotinum*, or one of the numerous bonesets, all of which are valuable honey-plants. There are many species of this important genus in the United States. *E. serotinum* is said by Gray to grow in low grounds from Maryland to Illinois, and South. No doubt Bro. Miller is right in the opinion that this plant gives those in his vicinity the major part of their autumn honey. The bee-keeper who has ample marshes near his bee-yard is in luck, as the home of the eupatoriums is in our marshes.

No. 2 is matrimony vine, *Lycium vulgare*. This is introduced from Southern Europe. It is planted, and, as Mr. Miller suggests, has run wild in some sections. It belongs to the nightshade, or potato family. I have often heard of this as a valuable honey-plant. If bee-keepers who live where this is hardy wish a shrubby vine, this is a good plant to grow. This family contains the potato, tomato, nightshade, tobacco, ground-cherry, etc. It is not very rich in honey-plants.

Mr. Miller is right again, for No. 3 is a mint. It is known as mountain mint, *Pycnanthemum muticum*. No wonder the bees work on this vigorously. The mints are wonderful honey-plants, and it seems to me to be more independent of the weather than do most of our honey-plants. It occurs to me that, if any plants are worthy of cultivation exclusively for honey, they are some of the perennial mints. I am in hopes to cultivate, in a small way, numerous mints in hopes to find the best honey-plant in the family.

No. 4 is the famous heartsease, *Polygonum Pennsylvanicum*. It seems that this plant does not secrete in all places at all times, or else has rivals that attract the bees from it.

No. 5 is tickseed, or bush trefoil, *Desmodium Dillenii*. It is one of the members of the clover family.

No. 6 is also one of the pulse, or clover family. It is *Phaseolus helvolus*, or wild bean. It is rather strange that these last are not honey-plants, as so many of the leguminosae are.

Agricultural College, Mich. A. J. COOK.

ODD-SIZED HIVES.

THE TRIALS OF ANOTHER DISGUSTED BEE-KEEPER.

We were greatly entertained with Rambler's account of Blake's tirade. Poor Blake has our heartfelt sympathy; for, next to a smoky chimney, an odd-sized bee-hive is the meanest thing on earth, and this I know from an aggravated experience. When we began bee-keeping we were sweetly beguiled into buying "Controlable" hives; but what they controlled we have failed to find; certainly not our temper, for not a supply-dealer kept any thing to fit; every thing must be made to order, costing more, or we must patch up as best we might, making needless work; and when done it resulted in some amusing experiments—amusing now in the light of added experience, but far from it at the time.

Our next venture was, at a time when swarms appeared faster than hives, to buy second-hand Simplicity hives from an accommodating townsman; but, alas for our ignorance again! We had no regular bottom-boards, but were told to let the hive project just far enough over the end

of a board to form an entrance. Note the result: In March, some evil spirit, either in the form of a dog, cat, or meddling person, pushed the hive forward four or five inches, of course chilling a fine strong swarm of bees. It was no fault of the hive, except the lack of a proper bottom, and we decided to adopt the standard frame, put in some secure hive; so this season we bought of a supply-dealer, not a manufacturer, as we ought, a lot of hives in the flat, and, by his unpardonable blunder, instead of giving standard frames he sent another odd-sized hive; and, as we had waited late, and the swarming season was at hand, we accepted them. Well, we then had three sizes of frames in a small apiary. We could say with Blake, "Durn the hives." At last the head of the family, being of a mechanical turn of mind, suggested a remedy, and we have just adopted it, and now we breathe a sigh of relief. We have uniform frames; we can unite or divide as we please. We cut enough off the bottom of each frame in the Controllable hives to make them standard depth, the length fortunately being the same, and cut enough off the bottom of each hive to make it right. The new ones we found, after trying three (and not liking them), could be remodeled; and, by getting new frames, be all right. As we have no suitable place prepared for doing such work, the cutting of frames was done in the open air, with the bees still on. We placed the rejuvenated hive under the shade of a tree some rods away, putting in first an empty frame; then carrying a full frame from the swarm to be operated on, we smoked as many as might be off, upon the empty frame, saved the end pieces, cut the comb, nailed on the bottom, and, putting it in place, went for another. It took two of us from half an hour to an hour to transfer each colony; but we think it will be worth the trouble and the time.

Our bees have done finely this summer, none of them making less than 35 lbs., and our best about 70 lbs. They are still working on buckwheat, and have been for about six weeks, as we sowed it for a succession, and we hope to have very little feeding to do for winter.

MRS. G. M. BARKER.

Natick, Mass., Aug. 28.

Thank you, my good friend, for the moral you have given us against adopting frames and hives of odd sizes. Your remedy is the rational one—cut them down to orthodox dimensions or smash them up.

ERNEST'S NOTES OF TRAVEL AMONG THE YORK STATE BEE-KEEPERS.

CLOSED-END VS. HANGING FRAMES.

I may say at the outset, that one of the main reasons why I made this trip was to learn something about closed-end frames, and, in particular, frames at fixed distances, whether closed-end or otherwise. Mr. Elwood, Capt. Hetherington, and almost all bee-keepers whom I visited among the York State hills, are using fixed frames of some sort. It will be remembered that Elwood and Hetherington use the closed-end Quinby frame and system. Their frame, however, is about 2 inches shorter than the regular Quinby, retaining, I believe, the original depth.

Well, after leaving Mr. Tunnicliff, Mr. Elwood and I started *en route* for one of his out-apiaries, and were discussing fixed distances and the rapidity with which they could be handled, as compared with the common suspended or hanging frames. Said I, "If fixed

frames can be handled as rapidly, and at the same time without killing bees as the hanging frame, they will be the frame of the future." Mr. Elwood did not boast very much what he could do—in fact, he did not make any very great claims as to the system, etc., which he was using. Some time ago, in an article he said he could handle the closed-end Quinby as rapidly as we could the hanging frame. I well remember at the time I did not doubt his veracity, but I did somewhat question his knowledge as to the manipulation of the suspended frame. I told him, as we approached one of the apiaries, that one of the privileges that I had long desired was to see him or some other bee-keeper using the Quinby frame handle them as rapidly as the hanging frame, and not kill bees.

By this time the yard which we were to visit loomed up in sight off in the fields at the foot of one of those big hills. It is located at some distance from the road, partly because of the protected position, and partly because it is secluded from those who might pilfer or meddle with the hives. We drove up under a low-spreading evergreen not a great way from the apiary. We there unhitched and led the horses a little bit further off and gave them their oats. As we did so, Mr. Elwood said there was a spring up on the hillside, and that, before eating our lunch, if I felt inclined we would go up and see it, and get a pail of water. After strolling a little distance among the rich undergrowth, suddenly a beautiful spring of water came in sight. Perhaps I might as well remark, by way of parenthesis here, that all the York State water, especially from the hillside springs, is clear and cold. In my own State of Ohio it is not very advisable for me to drink from different wells or springs—at least to any great extent; but on my bicycle tour through New York I drank freely from every roadside spring with impunity; and, oh how good, pure, and cold it did taste! What would I have given if I could have transported one of these springs, that seemed so common in York State, to my own home in Ohio! Doolittle had water from one of these springs piped to his house. I remember how thirsty I was, and how refreshing the water. Just thing of it—a running spring in the house, of beautiful water! But, to return:

Mr. Elwood and I secured the lunch-basket; and after hunting around for a good log to sit on, we partook of a hearty lunch; which, being dispatched, we put on our veils and proceeded to the yard. I had expected to see large Quinby hives; but, to my surprise, the brood-nest or brood-chambers were no larger, on the average, in cubic capacity, than are those in our eight-frame Dovetailed hives. I had supposed that the York State bee-keepers, like the Dadants, advocated and used large brood-chambers. So far as I was able to discover, however—in the production of comb honey at least—they practice contraction, and use brood-chambers no larger in capacity than an ordinary 8-frame Langstroth hive. The frame being 2 inches shorter than the original Quinby, 6 of these frames would be about equivalent to 8 of the Langstroth, I should say, without figuring. I was surprised to learn that all or nearly all of the bee-men of York State who have adopted the Quinby closed-end frame, like Mr. Elwood and Capt. Hetherington, use it 2 inches shorter, and it is no doubt a better frame for the reduction in length.

After lighting the smoker, Mr. Elwood and I entered the yard, and he proceeded to open up a hive while I was looking on with eager expectancy. The entrances were on the under side of the hive. Blowing a little smoke under to drive away the guards, he lifted off a case of sections. I expected to see those frames come

apart with a snap and an onslaught of bees. There was no snap or onslaught. He picked up and handled the frames as rapidly as you or I can handle suspended frames; and I am not sure but he manipulates them more rapidly. Mr. Elwood then examined continuously 25 or 30 other colonies; and when I came to think of the time he had spent in doing it, of the queens we had seen, of the brood surface we examined, I was simply astounded. I feel pretty sure that I could not have examined the same amount of brood surface in the hanging frame in so short a space of time. Did he kill any bees? Not one that I saw. Did the frames stick together? Scarcely at all; and yet the bees were hybrids. Here was a large yard of, say, over a hundred colonies. I do not remember to have asked how long it would take him to examine each one; but at the rate he handled those before me he would have gone through the whole apiary in four or five hours, and hunted all the queens besides. He did not move very rapidly; on the contrary, his movements were deliberate, but they counted.

I am well aware that this is a heavy testimonial for the closed-end frames on the Quinby plan; but I deem it but just to give it, because I know the bee-keepers of the West, and those who have been using the hanging frames, have somehow got the idea into their heads that the closed-end frames were simply intolerable, and that the bee-keepers who were using them were either very much behind the times, or so stubborn as not to be open to conviction that there might be something better. Indeed, when we consider the fact that nine-tenths of the bee-keepers of that section of New York where I visited are using fixed frames, and are intelligent and progressive men; and when we consider the other fact, that they make bees *pay*, we must admit that their system is not so clumsy and awkward, after all. Capt. Hetherington, years ago, used hanging frames faithfully, and finally discarded them for the closed-end Quinby. Hetherington, with his three or four thousand colonies; Elwood, with his 1300, and a great many others owning from 300 to 400 colonies in this part of New York, use only fixed frames, some Quinby and some Hoffman.

NO BURR-COMBS.

While Mr. Elwood was examining the hives I was pleased to note that there were no burr-combs on the tops of the frames. No, I do not believe I saw a single small spur. When I came to inquire into the matter I found he used top-bars fully an inch wide and $\frac{3}{4}$ of an inch thick—perhaps in some cases $\frac{1}{2}$ inch thick with *fixed distances*. I emphasize this purposely, because I believe that this is one of the secrets. I could not discover that any of the bee-keepers who had used fixed distances with top-bars $\frac{3}{4}$ of an inch thick and an inch wide, in that section of country, had used honey-boards. No, a honey-board was a thing that none of them had ever tried. With no burr-combs, what need had they of them? Now, if I am able to judge correctly, with fixed distances we can have *thinner* top-bars; but with hanging frames and no arrangement for automatic spacing, in order to do away with burr-combs there must be thicker top-bars. I examined into this matter very carefully all through this trip; and since my return home I feel confirmed in what I have said above in regard to the presence or absence of burr-combs, their cause and prevention.

I am very well aware that I have given some flattering testimonials for the Quinby system. I am not sure, however, that bee-keepers generally would not like the open or movable sides. The hive looked a little top-heavy also, and a good many bee-keepers incline toward the

shapely appearance of a thing as well as its practical utility with the two combined. I took some views of the apiary, and of the hives in particular, with the Kodak; and when the same are reproduced for GLEANINGS I will then explain in detail how and why Mr. Elwood can handle those frames so rapidly, which I can not do now without the aid of engravings.

After leaving this yard we visited two or three others. All that I saw were located in spots that were peculiarly picturesque. The scenery—perhaps a big hill on one side, a valley beneath, mountains over in the distance, all combine to make many of the locations grand in their outlook. As our time was limited we did not visit all of the yards, for one yard is largely a repetition of the others.

ELWOOD'S MAMMOTH BEE-CELLAR.

The next morning, as we expected to visit other bee-keepers, I took a walk around the premises. "Oh, yes!" I said, "there is that enormous bee-cellar that I want to see." Mr. Elwood conducted me to his mammoth repository under his large bank barn. If I remember correctly it was divided equally into two compartments, each one capable of holding perhaps 500 colonies. Just think of it—1000 colonies, practically, in one cellar! We bee-keepers who talk about wintering 50 or 60 colonies in a cellar successfully might find it another thing to bring through alive 1000 stocks in a single repository; and yet, if I understand correctly, our friend is generally successful. In this part of York State they have very severe winters; and, as a general rule, I found that bees are wintered indoors. I noticed that Mr. Elwood uses a sub-earth ventilator, and he believes it to be a good thing at times. He does not, however, use it with its mouth outdoors open full width most of the time, but only on occasions.

"What do you do," I said, "when it becomes too warm, and the bees get to roaring—that is, uneasy?"

He took me out to the mouth of his sub-earth ventilator, and showed me how he could, by enlarging the opening, let in enough cold air to reduce the temperature enough to accomplish the desired end. The winters being so cold, he generally has no trouble from a too high temperature in the cellar.

"Then you cart all your bees home," I said, "and finally put most of them into that cellar?"

He assured me that they did. At the risk of letting the readers of GLEANINGS think (if they do not already think so) that I have gone pretty nearly crazy on fixed distances, I will remark again, that, were Mr. Elwood using hanging frames, or, as he calls them, "swinging" frames, the necessary preparation for getting a colony ready for moving—that is, so many of them, would render moving impracticable. I do not wonder that, with their rough and uneven roads, and their terrible big hills, they all use frames at fixed distances, even if there were no other reason why they should do so. I should like to be on hand when the 1000 or 1200 colonies are deposited in the front and back yard, just preparatory to putting them into the cellar. It must be a sight to behold, and I hope our friend Elwood will some day call upon his nearest photographer to give us a view of the scene.

Before I forget it, perhaps I had better explain that, instead of removing the bottom-board after putting the bees into the cellar, the boards have a hole six or eight inches square, in the center, and this hole is opened or closed by means of a convenient slide. When contracted it acts as an entrance during the summer season; and when opened wide it gives ample bottom ventilation while in the cellar. While we were discussing these things, we

slowly emerged from the cellar, and finally entered the shop, or honey-room, partitioned off from one end of the barn. I discovered here that Mr. Elwood uses the section-holder that we use on the Dovetailed hive. When we first introduced it I was not aware that such extensive bee-keepers were already using it and liked it, although I knew that the idea was by no means new. The fact that such a man as Elwood uses them, in preference to even the T super, confirms me in the belief that they must be one of the best comb-honey arrangements made.

I noticed in this honey-room that friend Elwood uses a four-piece section with flat-bottom foundation. The sections are put together with a machine of his own invention, and they are glued solid together. I tried to break several of the sections when so put together. They certainly were very secure, and no ordinary amount of hauling, even over rough roads, would jar them out of true.

"There," said Mr. Elwood, pointing to a few crates of honey, in one corner of the room, "is all the *white* honey I have obtained this year."

"That will not be your entire crop?" I said.

"Oh, no!" He replied, he would get *perhaps* 25 lbs. per colony of mixed and buckwheat honey. The basswood has been almost a failure with him during the past season, and the clover was but little if any better. It was the worst season he had experienced in many years.

"What is your average per colony?" I asked.

"If we get 50 lbs. we are satisfied," he said.

Let us see—50 lbs. multiplied by 1300—65,000 lbs. It seems as though he ought to be "satisfied," if Capt. Hetherington (and I presume he does) obtains in a fair year a proportionate amount, his crop would make the "eyes" of some of us bee-keepers stick out pretty prominently.

HYBRID BEES AND BUCKWHEAT HONEY.

Speaking of buckwheat honey above reminds me of the fact that Mr. Elwood keeps hybrid bees almost exclusively. He rather prefers them because they are a little better for working on buckwheat. Through my trip in York State on the bicycle, I believe I do not exaggerate when I say that I must have seen thousands of acres of buckwheat. The farmers, instead of confining their crops to the proceeds of a single acre, raise it by the ten-acre fields; and I believe it is usually a paying crop. I was pleased to notice, also, that the Japanese buckwheat was being introduced very largely. The bees work on it just as industriously as they do upon any kind of buckwheat. Several fields that Mr. Elwood and I passed were fragrant with the aroma. In fact, I passed on the bicycle so many buckwheat-fields that the odor became sickening to me, as I do not like buckwheat honey. But the people in York State, I am glad to know, are not like me. At most of the hotels where I stopped, they had this black-looking honey on the table. By making inquiries I learned that some of their guests preferred it. They like that rich dark-looking honey of their fathers. I personally came across a great many people who prefer buckwheat to any other they had ever eaten; but I am afraid I should have to go a good way in Ohio before I could find one who had this preference.

Mr. Elwood's hybrid bees I found were cross. Let me relate a little incident.

I told Mr. Elwood I should like to make some detail photographs of one of his hives. We accordingly proceeded to the yard. He pointed to one that showed well, and was about what he used in all his apiaries. "I will just change this cover," said he, removing one from another hive, "and put it on the one you are about to photograph." As he did so he happened to let

it drop on the hive to be "Kodaked,"—enough so as to stir up the sentinels. Neither of us had a veil on. I stood at a respectable distance, say six or eight feet, in front of the hive, Mr. Elwood a little in the rear. My Kodak was all primed and ready. Just then those pesky hybrids began to pour out like a hailstorm. I wanted to run. Sting—it seemed as if I could not endure to take even a snap shot at those fellows—or, rather, at their hive. The first one planted a sting right on my nose, and, of course, the rest of them saw fit to visit the same vicinity, attracted by the poison. Now, you know I could not stand that. My ever ready veil was in my hind pocket. My eyes were suffused with tears, and I hastily laid the Kodak on the ground, whipped out the veil, and drew it over my head in some fashion or other. Somehow or other I felt like running. How it would look for me, I thought, on the editorial staff of GLEANINGS, to pick up my things and run in wild haste out of the yard. The veil was pulled over, but those scamps did not stop to buzz in front, but with provoking deliberation crawled up under and made things worse. I pulled out the Kodak, and said, "Now or never!" and while the tears were streaming from my eyes with pain, I managed to be able to see enough from one eye to get a view of the hive. This time I did not wait, but touched the button, and the shot was taken. As I did so I looked up to see where my friend Mr. Elwood was. Presently I espied somebody running, and his arms were revolving about his head in a characteristic fashion. Now, Mr. Elwood is slightly baldheaded, and his hat was gone. As I saw him rub sting after sting out I did not blame him for retreating. I understand from his men that he can stand as many stings without wincing as anybody else; but it did tickle them to see their big boss run from the bees. One of Mr. Elwood's little boys was heard to cry out lustily about this time, for he was out in the yard bareheaded and barelegged. His father directed him to his mother, and then called out: "You didn't catch me in that picture, did you?"

"As you were running, I presume I did," I replied; at least, I was mean enough to say I hoped so. I took time now to rub the stings out of my nose, and mentally reflected how it would look to go around among the bee-keepers, the representative of GLEANINGS, with a nose somewhat immoderate in size. It did not swell, however, and after a couple of hours I felt no ill effects. As we started to leave that morning for another ride among bee-keepers with Mr. Elwood, this little boy who had been stung came out to greet us with a good-by. His face was considerably swollen, and it looked as if he had been stung by a bee. My camera was attached fast to the bicycle, or I would have been cruel enough to have taken his picture. Mr. Elwood, although stung much worse than I, seemed to show no ill effects.

In order that we might visit together, the bicycle was tied on to the wagon, and we started for the home of Mr. Julius Hoffman, by way of the Van Deusens, the people who make that beautiful flat-bottom foundation. We went over some terribly bad hills—hills that I should not care particularly to have gone over with a bicycle; and I was glad there were some good horses ahead of me that were used to that sort of business. More beautiful scenery was presented to me, and ere long we were overlooking the flat-bottom valley which has been before described by our friend Rambler.

AT SPROUT BROOK, N. Y.

In a few moments more we were having a cordial handshaking with the Van Deusens. We laughed and talked about Rambler and his

visit at their place. In view of his experience, I did not ask to go through their establishment; but I was shown some of their beautiful foundation. They have quite a large factory, and evidently do quite a business. I took particular pains to notice that this country was very flat bottomed—an appropriate location for making foundation. We were cordially invited to stay and take dinner; but as my time was limited, I explained that I should have to be moving along.

SNEEZE-WEED HONEY.

PROF. COOK ALSO TOUCHES UPON THE MATTER OF MEDICINAL HONEY.

I have received from Mr. C. P. Coffin, Pontotoc, Miss., a plant for name, together with some suggestions and questions which are of general interest, and so I am pleased to comply with his request and answer through GLEANINGS.

The plant is a species of "sneeze-weed," *Helenium tenuifolium*, which Dr. Gray says has become a naturalized weed through the Southern United States. It is one of the compositae, and so related to the goldenrods, asters, bonesets, beggar-ticks, etc. We can not wonder, then, that it furnishes a generous amount of nectar. It comes of a sweet family.

Mr. Coffin says this is very abundant in Mississippi; that it occupies all waste lands and commons, and is marching on to possess all unoccupied, vacant, and uncultivated territory. It grows as thick as oats or wheat, and crowds out all other plants. It is often the sole adornment of cemeteries and front yards. We see, then, that it is like the ragweed and mayweed north, a monopolist of first rank.

The people in Mississippi know it as "bitter weed." The bees store large quantities of honey from this plant. Mr. Coffin says it seldom fails to yield bountifully, so that the bees fill their hives solid—both stories—with this honey. But this honey is of no value, except for wintering. "It furnishes an unfailling supply for this purpose." But it spoils the goldenrod and aster honey, which is also abundant, and valuable for the table as well as for the bees.

Mr. Coffin quotes an article from a Boston paper, to the effect that an English physician reports that a small bee of Tasmania gathers eucalyptus honey, which has special and peculiar physical characteristics, and has very valuable therapeutic or medicinal properties.

Mr. Coffin asks if the Tasmanian bees could in any way add to the virtues of this eucalyptus honey. I should argue no. True, bees modify nectar, or change it into honey; but there is no reason to believe that different bees affect the honey differently. I presume the honey varies because of the source from which it is derived, and not from the bees that store it.

Mr. Coffin urges further: Granting that the position taken by the English physician is correct, may we not reasonably conclude that honey collected by our *own* bees from plants of known medicinal characteristics would have like therapeutic virtues? For instance, suppose an apiary to be near a large field of hoarhound, which is universally recognized as efficacious in throat and lung affections. Would not the syrup thus made in Nature's laboratory by these wonderful chemists—plants and bees—containing the very essence of the plants, be superior to the syrup which we may make by boiling the leaves with sugar?

In reply, let me say: We must not put too much confidence in such reports. As a people we overestimate tremendously the virtues of medicine. Nature is the great healer. Medi-

cine may occasionally help, but I fear it as often hinders. Dr. O. W. Holmes once said—and who ought to know better?—that it were better for the people were all the medicine of the world cast into the sea; but it would be awful on the fish. Yet if people are to medicate, I for one would urge honey. It is certainly nutritious and wholesome. It has the rare quality of medicine—it is safe.

Again, I do not believe that the nectar secreted by plants necessarily or even probably partakes of the nature of the juice or tissues of the plant. The definition I give my students of glands—and I believe it a correct one—is that they are organs that can take elements from sap or blood, and form a substance peculiar to themselves and unlike any thing else in the plant or animal. Thus, secretions are not like the tissues that secrete them or the liquids from which the elements were derived. The milk of the cow is not blood or beef, nor like them. No more is the nectar of plants—the secretion of plant-glands—like the sap or tissue of the plant. This secretion is a new formation, of the glandular cells, for a specific purpose—to attract insects—and is specific in its character as well as in its function.

Again, we have plants with poisonous juices. These often secrete nectar, but that is not poisonous. Were it so it would poison the very insects it was formed to attract, and so defeat its very purpose.

Mr. Coffin continues: "Nothing was made in vain. May it not be that this bitter honey has very valuable medicinal properties? If so, a knowledge of the fact would be very important. As this plant secretes nectar abundantly from July 15th to September 15th, when there are no other nectar-secreting plants in bloom, the honey can be obtained unmixed with other kinds of honey, and could be put on to the market very easily and cheaply."

I would answer, that morphia and quinine are vegetable products, and no one may say that any vegetable product is worthless or without virtues until he has demonstrated the fact. On the other hand, he should be just as slow to announce virtues till they are demonstrated by actual experiment. Such proofs—like all valuable scientific facts—must come from induction, not deduction. We must demonstrate by actual test that this honey is medicinal; then, and then alone, can we recommend its use in therapeutics.

This honey might be extracted and sold cheaply for winter food, in case it is good for that purpose in all climates, and could also be sold for such manufacturing purposes as forming printers' rolls, etc., where the flavor is not an objection. In case we have many such seasons as the present, where in Michigan the bees have not been able to collect enough even for winter, there would be a good market for the first-named purpose. As this honey is so sure and abundant, it could doubtless be sold at a very low rate. Possibly it would do to use in making cigars, where, I am told, much honey is used; and then if it has medicinal virtues it would be right where it would be needed.

Agricultural College, Mich. A. J. Cook.

Friend Cook, I am exceedingly glad to hear you give utterance to the sentence, "*As a people we overestimate tremendously the virtues of medicine.*" As I look upon humanity day by day, I am more and more forced to the conclusion that "we as a people" are floundering in the dark mazes of superstition and ignorance, especially in this matter of *dosing* ourselves. Just think of it! There are at present in the

United States (or at least have been until quite recently) *great factories* built up to make electric belts, medals, and charms, to cure diseases, while every educated man knows that they have not the remotest effect whatever on disease of any sort. In fact, there is not even any *electricity* about them. People feel bad; and if they do nothing at all they almost always feel better after a while. In the meantime they purchase these advertised trinkets, and then give the *trinket* the credit of the cure. Of course, we are a little ahead of the Chinese, and the heathen with their signs and taboo, but I am sure that the large amounts of money that have been constantly paid for patent medicines, and, in fact, for almost all kinds of medicine, is a great mistake and a blunder. People who take no medicine at all are just as well or better off. I wish those words of Dr. Holmes might be rung out over land and sea, until they reach every household. A certain remedy or a certain doctor gets to be the rage, and nobody discovers that the whole thing was only a hallucination until thousands of dollars have been wasted and thrown away. Our friend touches on hoarhound honey. Perhaps he has not noticed that we have it for sale by the hundreds of pounds, if wanted; and it is as strong of hoarhound as is hoarhound candy. To me it is delicious with my bread and butter; but I have not a particle of faith that it has any remedial virtues whatever; in fact, I can hardly believe that hoarhound in any shape has any effect whatever on coughs and colds, but the hot water taken with it *may* have. Now, dear friends, it may be that I am going somewhat to extremes in this matter of medicine and remedies; but I think our intelligent readers must admit that there is at least a great amount of truth in my position. I do not mean to reflect on our regular physicians for I believe that most of them understand me, and believe, at least to a great extent, just as I do. Take the advice of an intelligent and progressive physician of the present day, and you will not take very much medicine.

STRONG EVIDENCE FOR ONE AND THREE-EIGHTHS SPACING.

THE TESTIMONY OF BARON BERLEPSCH AND OTHER EMINENT GERMANS.

I am glad to find that you give the matter of spaced frames so much attention in your valuable paper, as I think successful bee-keeping demands a brood-frame with fixed spaces. If so, we should certainly know the exact and right distance from center to center. Why the bee-keepers of this country differ so much yet in regard to the exact measure of spacing brood-frames, I can not understand. There is only one way to get this distance right. It is, to find how far the bees, when left to themselves, build their combs apart in the brood-nest. About twenty years ago I settled this matter to my own satisfaction. I began by using a spaced frame of $1\frac{1}{4}$ inches from center to center, and

found that distance too wide. At that time I used, in hiving natural swarms, only small starters in the frames, and I found the bees would, in building down their combs, invariably draw in the combs toward the center of the brood-nest, so that the lower part of the comb would be built out of the frame. They would do so until I reduced the space so as to measure only $1\frac{3}{8}$ from center to center. As this matter seems to me to be of great importance, I will here quote from whom I believe to be the best authority on the subject. The Baron von Berlepsch, in his unequalled work, *Die Biene und ihre Zucht* (The Bee and its Culture), says: "Dzierzon, the inventor of the movable comb, gave $1\frac{1}{2}$ as the right distance, until Wieprecht* made exact measurements on straw hives that were built out with straight combs. He found, that, although some variations were noticed, in 49 measurements the average distance from center to center of combs was $1\frac{5}{16}$ inches.

"The correctness of this statement, I (von Berlepsch) can affirm with the utmost certainty, as I, in company with Kalb,† also made 49 measurements, the result being $1\frac{1}{16}$ inches as to the average distance."

The German foot is $\frac{1}{4}$ inch longer than ours; therefore $1\frac{5}{16}$ in. of Berlepsch's German measure would be equal to $1\frac{11}{16}$, or scant $1\frac{3}{4}$, of our measure. But as the wood of the frames will shrink, and also wear off some, I make the close-fitting parts of my frames exactly $1\frac{3}{4}$ wide, and I believe this to be the best width. To make the spaces more than $1\frac{3}{4}$ will be antagonistic to the nature and well-being of our bees.

If we, for instance, space the combs from center to center so as to measure $1\frac{1}{2}$ instead of $1\frac{3}{4}$ inches, then we have an empty space of $\frac{1}{4}$ inch between two combs of brood instead of $\frac{3}{8}$, as it ought to be; and it will certainly require more bees to fill and keep warm a $\frac{1}{4}$ than a $\frac{3}{8}$ space. In a $\frac{1}{4}$ -inch space, the breeding bees from two combs facing each other will join with their backs, and so close up the space between the two brood-combs; if this space is widened, however, to $\frac{1}{2}$, the bees can not do this, and more bees will be required to keep up the needed brooding temperature. What a drawback this would be in cool spring weather, when our colonies are weak in numbers yet, and breeding most desirable, can readily be understood.

My hives hold 11 brood-frames. If I space them $1\frac{1}{2}$ the bees would have to occupy an $\frac{1}{4}$ -wide space of unnecessary and useless room between the brood-combs through the whole length and depth of the hive, as compared with $1\frac{3}{4}$ -spaced frames. Wider spacing than $1\frac{3}{4}$ will also favor and encourage the building of drone-cells and the raising of drones.

In conclusion I will say, Use spaced frames, and have them not more than $1\frac{3}{4}$ apart from center to center. JULIUS HOFFMAN.

Canajoharie, N. Y., Aug. 23.

Many thanks, friend H. The evidence that you present out of your long and extended experience, for $1\frac{3}{4}$ spacing, seems to me to be convincing. At first I thought Nature was against us in urging $1\frac{1}{2}$ inches; but I am very glad to believe that she is on our side, although my good friend Doolittle may argue that she is on his side. If the bee-keepers ultimately adopt fixed distances it is highly important that this distance be settled accurately in the first place. Berlepsch (whose most valuable researches we

*A noted bee-keeper and writer. -J. H.

†A prominent bee-keeper.

value so highly), as we well know, was very careful in his experiments, and his conclusion can not be lightly esteemed. Unless some one else shall bring some incontrovertible evidence to the contrary, let us consider $1\frac{1}{8}$ spacing as the right distance for the average bee-keeper. Perhaps I should remark that friend Hoffman prepared the article above in response to my request made to him in person while I was visiting at his home. In my Notes of Travel I will give an account of my visit to his place later.

ERNEST.

ZINC QUEEN-EXCLUDERS.

A SPLENDID TESTIMONIAL FROM A CALIFORNIA APIARIST.

I have taken so much comfort with my 450 zinc queen-excluders this season, I am sure it will be doing my neighbors a kindness to tell them how they work. My hives, and, in fact, nearly all the hives in Ventura County, are made with a bee-space in the bottom and top of both super and brood-chamber, which, when the super is on, leaves $\frac{3}{4}$ of an inch space between the super and the brood-frames. I have always thought this a mistake; but when I began to think of using queen-excluders, I saw that, if a plain unbound zinc excluder, the size of the outside of the hive, were laid on the brood-chamber, and the super on the excluder, the bee-spaces would be all right. I ordered 480 of Root's No. 1 unbound zinc excluders, large enough to fit my hives. I think No. 1 the best, because they allow the bees to pass up and down more freely than the break-joint excluders. After trying 450 of these unbound excluders one season, I am satisfied that they are better in every way than the bound excluders. The super is easily lifted off the zinc, and, by taking hold of one end of the zinc and pulling up and out, they can be peeled off almost like cloth; and if they bend a little, just turn them upside down when you put them on again. I bought the excluders because I had a good many drone combs in my supers; but I would not do without them now, if my super combs were all worker size. It makes a fellow feel good to open a super just before swarming commences, and find about a square foot of drone comb all cleaned up for the queen to lay in. It is ever so much nicer to fool the bees in this way than to shave the heads off the drones. You don't always get around in time to shave the drones' heads off, and what a lot of honey is wasted in rearing them!

When you have no excluder on a ten-frame L. hive, the bees will fill about 7 combs in the brood-chamber with brood, and then run it up in the super instead of filling the brood-chamber clear across. This brood in the super is a great nuisance when you are extracting. In California we leave our supers on all the year round; and if the super is full of honey in the spring, the bees will build up faster than they would if the hive were contracted. Another point I did not discover until I put excluders on all my hives: When the queens are allowed to go into the supers, a good many are knocked off on the ground, and lost, when brushing the bees off the combs. I did not find a fourth as many queenless colonies after extracting this season as usual. I found a few queens that could run up and down through the excluders, but not enough to trouble seriously. If I had my choice, however, I would have the perforations $\frac{1}{10}$ of an inch wide, instead of $\frac{1}{8}$ in. I have been experimenting by putting queens in a little box, and

covering it over with different sizes of perforated zinc. I found but few queens that would crawl through the $\frac{1}{8}$ in. perforations, but could not find any small enough to go through the $\frac{1}{10}$ in., and I could not see that it made any difference to workers.

It is easier to take honey out of a super if you have a queen-excluder under it, because the bees do not build so many brace-combs below the super combs. Other large bee-keepers around here are experimenting with them, and I think all the progressive ones, Mr. Mercer included, will soon have them on all their extracting hives. Nearly every bee-keeper who comes here and sees how they work, says, "I wish I had them in my apiary." J. F. McINTYRE.

Fillmore, Cal., Sept. 1, 1890.

You have given us some valuable testimony, friend M., for the perforated zinc for extracting. This and the bee-escape promise to work almost a revolution in the methods of producing extracted honey. You are exactly right, friend M., as to the size of the perforated zinc. By careful experiments which we have been making, we decided that $\frac{1}{10}$ was correct. Before us is some of Dr. Tinker's beautiful zinc, and it is a pleasure to us to say that his zinc so far stands at the head. By carefully measuring, we find that the width of his perforations strikes $\frac{1}{10}$ exactly. The fact that all three of us arrived at this conclusion independently—you in California, and two of us in Ohio—makes the evidence almost conclusive that $\frac{1}{10}$ must be correct. We are at work on a new set of dies. They are to be gauged to this size as nearly as the best machinery can be made to do it. Mr. Alvah Washburn, who made the original comb-mills, and who, in fact, has done all our fine work, is to make the dies, and we hope ere long to have a zinc that no queen will go through. Our old zinc measures about $\frac{1}{10}$, and that is the reason why we change.

Quite incidentally, friend M., you mention another point. In a Langstroth hive, you say bees will fill seven frames of brood, and then go into the super instead of filling out the brood-chamber clear across. That is just the reason why I advise everybody to use the eight-frame hive. In the name of common sense, why have a hive any larger than the average brood-nest? We want the bees to fill the brood-chamber entirely with brood, or very nearly so; and then if they are able to get any honey we want to compel them to put it just where *we* want it—in the supers.

E. R.

GOLDENROD.

THE BEES ARE JUST "WHOOPIING UP" THE HONEY FROM IT IN MICHIGAN.

Our aged friend J. L. Davis, of Holt, Mich., once said to me: "I am very fortunate in the large marsh" which extends for some distance in front of his house. Many people would not appreciate readily the wisdom of this remark. A marsh for a dooryard and constant outlook is not generally among the aspirations of those aesthetically inclined. But should such a one visit friend Davis at this season, and look out

upon his field of autumn bloom, with the goldenrod predominating, he would hardly criticise our venerable friend, even from the standpoint of aesthetics.

But aesthetics was not in our friend's mind; he was thinking of honey and his pocket-book, and well might he; for, many a year his chief honey product has been from these same autumn flowers.

Friend Root, you and I have pictured to ourselves the joy which must come to the desert pilgrim as he comes to an oasis. Well, that is the Michigan bee-keeper's condition just now, who has a wealth of autumn bloom to draw upon. Our bees have been idle the whole season till now, when they are just "whooping it up" as our boys say. We can smell the honey in the evening for rods from the apiary.

I wish, Mr. Editor, any skeptics on the matter of goldenrod as a honey-plant might visit me now. Our bees are just swarming on it. Yesterday I saw asters, goldenrods, boneseeds, and the tall sunflowers just alive with bees. I have never seen bees very much on the sunflowers (*Helianthus*), and so I was very much interested in this observation. We find the bees are not working much on the buckwheat. It may be because they prefer the autumn flowers. If this is the explanation, we are glad of their preference, as we prefer the goldenrod to the buckwheat honey.

A. J. COOK.

Agricultural College, Mich.

We are very glad indeed, friend Cook, to know that we are going to have some honey, even if it does come at the eleventh hour.

OUR QUESTION-BOX.

With Replies from our best Authorities on Bees.

QUESTION 168.—*I want to start an out-apiary, and will have to haul my bees back and forth, full and spring. Would you advise me to adopt some device to space the frames at fixed distances, for the sake of security in hauling, and to make sure of exact spacing?*

I would.

Illinois. N. W. C.

MRS. L. HARRISON.

I think it would pay you well to do so.

New York. C.

G. M. DOOLITTLE.

Until I learn better I should advise you to do so.

New York. C.

P. H. ELWOOD.

I am not authority, but I think not. How is this, Dr. Miller?

Michigan. C.

A. J. COOK.

For this, as well as for several other reasons, I want my frames at fixed distances.

Illinois. N. C.

J. A. GREEN.

I use small blocks between the frames at the bottom for moving short distances. The tops will usually stay in place. It is a very short job to block the frames perfectly secure.

Ohio. N. W.

H. R. BOARDMAN.

If I were hauling my colonies I should take care to have my frames stationary. A device such as we use for shipping bees, placed on top of the frames, at the front and back, keeping them apart, is sufficient, and is easily put on and taken off.

Ohio. S. W.

C. F. MUTH.

I have a horror of fixed frames, and therefore advise the questioner to do a pile of thinking about other devices first. Perhaps for that style of gipsy bee-keeping that keeps continually roving about, fixed frames may be best.

Ohio. N. W.

E. E. HASTY.

I would advise you to use my patented hive. There are two reasons why I might give such advice—one that I am dealing in them, and the other that I think it to be the best for the purpose you mention and every other. I leave you to decide from which I gather my inspiration.

Michigan. S. W.

JAMES HEDDON.

I've used movable frames a quarter of a century, and they have always been *movable*. I never tried a fixed frame, and it seems to me I should feel hampered with them. Still, in hauling, a hive would be more movable if the frames were immovable. If a somewhat exact distance is required to avoid brace-combs, fixed distances may become a necessity.

Illinois. N.

C. C. MILLER.

That depends upon whether you handle your combs and bees or not. If you manipulate your combs as I do, I answer, no, but have spacers to apply when hauling. But if you do not overhaul your bees occasionally it is well enough to have the combs at fixed distances, or, what would be as well, nail them down with 10-penny nails; or, what would be cheaper still, use old-fashioned box hives or log gums.

Vermont. N. W.

A. E. MANUM.

That depends. If the frames are fastened to the quilt or honey-board by the bees, and you use a spring wagon, I should say no. If a wagon without springs is used, and six or eight inches of straw is placed under the hives, and care is exercised in driving, there will be no need of fastening the frames. I have taken them in the last way ten miles, and not a frame broke loose.

Ohio. N. W.

A. B. MASON.

Yes, I would advise you to adopt (or, better yet, invent) some simple device for holding the suspended frame when moving; and if patented I should like an interest in it to the extent of one individual right, for it has been a great bother to me to fasten frames when moving. If I could have the Quinby closed-end in moving, and the Gallup after they were moved, I should be suited; but I don't know of any slight-of-hand whereby I could change them at will.

Wisconsin. S. W.

S. I. FREEBORN.

All the frames of our hives have a space-wire to keep them separated at the bottom, thus:

and as the arms of the suspended frames are glued to the rabbets, we haul our bees from one apiary to another, when necessary, without any other device, *in spring*. But we would not haul them in the fall, when the combs are full of honey, without fixing them by small wire nails half driven in the arms. See pages 167, 168, of our book.

Illinois. N. W.

DADANT & SON.

If it is necessary to haul bees to and from the out-apiary I should by all means adopt a close-fitting end frame of some kind. We are just moving an out-apiary in which half of the hives have closed-end frames, the others hanging. The closed-end frames can be prepared in a minute without opening the hive. The loose frame requires any amount of tinkering and waste of time. If loose frames are used I should certainly apply some of the many devices for keeping them at fixed distances. Any device

that is to be put into the hive and taken out again is a nuisance, and liable to get lost or broken.

New York. E.

RAMBLER.

For a hanging frame we don't use any thing to keep the frames at fixed distances. Any device to keep the frames at fixed distances would necessitate a movable side to the hive. When we move bees in the L. frames, we lay a piece of our frame timber $\frac{3}{4}$ x $\frac{1}{2}$ flatwise across the ends of the frames, and drive 3 or 4 wire 4-penny nails down through the piece and the frame below, into the rabbets of the hive. That will hold the frames secure. Then confine the bees as you please, and go ahead.

Wisconsin. S. W.

E. FRANCE.

No. I would secure with staples across the center of the bottom-board a piece of No. 12 wire, bent like a worm  interferes but little in setting the frames in the hives, and prevents the swaying motion in hauling. Then I would keep a set of notched strips of tough wood the length of the width of the hive, $\frac{1}{2}$ inch wide by $\frac{3}{4}$ inch deep, cutting the notches $\frac{1}{2}$ inch deep; place these down on each end of the top-bars while hauling, thus:

 Frames are thus spaced and stationary, but free when wanted so.

California. S.

R. WILKIN.

I am surprised to note that so many recognize the need of something to hold the frames at fixed distances. It is true, in some localities, hanging frames can be hauled without fixing; but even then, the hives must be on springs or loose straw, and, worse than all, slow and careful driving is necessary. We have tried it, and know. Another thing, there are localities where hanging frames could not be hauled without fixing. See Notes of Travel at Elwood's, elsewhere in this number. If fixed frames, or, if you choose, closed-end frames, can be manipulated as rapidly and as easily as the hanging frame, why bother with the latter? Note particularly what Rambler says, and also what is said elsewhere, regarding the rapidity with which Elwood handles closed-end Quinby frames.

E. R.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

MICHIGAN BEE-KEEPERS' STATE MEETING.

I wish early to call attention to the Michigan State Association, which holds its next meeting on New Year's day at the city of Detroit. It will be remembered that the Detroit meeting of the National Association was one of the best ever held. We propose that this next State meeting shall come well up to that grand one. We hold it on New Year's day so all can get half rates. We hope for a very large attendance from Ontario, New York, Ohio, Indiana, and other States. It is to be hoped that all will plan before hand to be on hand, and that the very poor honey season may not keep any one at home.

Lansing, Mich.

A. J. Cook.

HOW TO GET RID OF DRONES.

We are having quite a honey-flow from what is commonly called "smartweed," which, by the way, as you doubtless know, makes the very finest honey. All of my 25 colonies are rushing out and in at a furious rate, with just one exception. From one hive but few bees have been going out and in, while a good many loafed around the entrance. The few that did go out to work went and came in a lazy, dragging fashion, quite in contrast with the busy rush from the other hives. Upon examination by lifting out a frame, I found that, while they had some sealed honey and a considerable amount of brood, the hive seems literally overrun with drones. I estimated the number at fully half the swarm. Now, what shall I do to get rid of these fellows, as they will undoubtedly eat up the whole store and leave the colony destitute?

I wintered 11 colonies last winter, and increased this season to 25 by natural swarming. They have made no surplus yet; but I think, with the exception of three or four late swarms, they will be in excellent condition for winter. The honey-flow will probably continue here three weeks, or till about the middle of September, so I may get some surplus yet.

Waterman, Ind., Aug. 25.

M. STURM.

Your queen is evidently a drone-layer. Replace her and trap out by perforated zinc the surplus of drones.

THE ROCKY MOUNTAIN BEE-PLANT—A REPORT FROM ITS NATIVE HOME.

Friend Root:—I address you thus familiarly because of the friendly way you have of talking in your A B C book, which came promptly to hand, together with 25 cts. returned, on account of clubbing with GLEANINGS. This was altogether unexpected. Is the inclosed sample of our most productive honey-plants in this vicinity the spider-plant, illustrated on page 253 of said book? You will see that it differs somewhat, as this has only three leaves on a stem, and the seed-pods all hang down, even when very small; and instead of the flowers opening about sunset they are open all day and covered with bees the whole day long; and instead of from 12 to 20 flower-stalks to each plant, I should say from one to two hundred. The small stalk that I picked this sample from had 57 more like it, and is only about two feet high, while there are thousands of them from five to six feet high on high ground, with no water. There is one peculiarity about the plant that you do not mention, which makes me think that they are not identical. This plant with us is something like the bee, being very sensitive. If let alone or handled very gently it is all right; but if you strike it a blow, or kick, or handle roughly, it instantly gives out a very strong and disagreeable odor—that is, the stalk and leaves, but not the blossoms. Its thriving so well on all kinds of soil, by the roadside or on hard dry clay, and with no water, makes it the honey-producer of this vicinity, at this season of the year, for it is always ready, whether the alfalfa crop is in bloom or has been cut and stacked.

If I can give you any further information concerning this Rocky Mountain country I shall be happy to do so in my humble way.

HOMER BROWN.

Taylorville, Utah, Aug. 30, 1890.

Friend B., the plant you send is not the spider-plant, as you suppose, but only a near relative. The spider-plant is *Cleoma integrifolia*, while this is the Rocky Mountain bee-plant, or *Cleoma pungens*. The flower of the spider-

plant is very much larger; besides it differs in other ways. As they so strikingly resemble each other they are often confused. While the spider-plant bears transplanting as well as a tomato, the Rocky Mountain bee-plant is very touchy, and it must be handled in transplanting with the greatest care, or it droops and dies at once. I have before noticed the sensitive peculiarity you bring out so vividly. It seems to be one of the high-toned plants. Prof. Cook has already tested it as a honey-plant by the acre; but it does not take as kindly to our soil and locality as it does with you. We shall be glad of any information as to the quality and quantity of honey it produces in its native wild. Some of the seed-catalogues have been giving it an undeserved boom, under another name.

ASAFETIDA TO STOP ROBBER BEES.

I have used it two or three seasons, and find it good, that is, on colonies that rob through a poor honey-flow. They go in and out without being detected. I had one colony that was going it strong this season; but after a 5-cent cake of asafetida had been on their bottom-board 12 hours they were challenged as soon as they entered a hive; and as they could not give the password they were soon ejected or killed. Their perfumery gave them away.

SAMUEL HEATH.

Tidal, Pa., Aug. 23, 1890.

I am not surprised at the result of your experiment, friend H. Asafetida has so pronounced an odor that it enabled the bees to tell their friends from their enemies without trying very hard.

HONEY FROM THE COTTON-PLANT.

I have been out peddling honey to-day. I sold \$27.00 worth at 11 cts. I send you a small sample of it. The sample is cotton honey; that is, it is from that source. In examining your A B C in regard to honey-plants you say nothing about honey from cotton. My bees made 2 lbs. per day for two weeks from cotton. I could give you an idea as to all of our honey-plants, but probably with no interest to you. I shall get about 20 lbs. of surplus, on an average, from my bees.

J. F. TEEL.

Elmont, Texas, Aug. 15, 1890.

The sample of honey received compares favorably with clover honey, both in flavor and color, and is much above the average quality of southern honey.

TOMATO JUICE FOR PROPOLIS.

There is one thing I have just discovered that I never knew before, and that by accident. I had been taking off honey, and had my hands well stuck up with propolis. As I had some tomatoes that needed fixing up I got some of the juice of the vines on my hands. When I came to wash, and rub soap on my hands, the propolis came off in a hurry. If I had known that years ago it would have saved me much trouble.

JAPANESE BUCKWHEAT FOR HONEY COMPARED WITH COMMON.

I wish to write a word about buckwheat, as this is a buckwheat section. Last year there was some of the Japanese buckwheat sown for the first time near here. To-day I thought

I would examine and see how the bees were working. I looked at a piece that had Japanese and the common buckwheat, both sown in the lot side by side. The day was good, and the buckwheat was fresh and nice. I think by the looks that there were ten bees on the common to one on the Japanese. How is it in your section?

BEN FRANKLIN.

Franklinton, N. Y., Aug. 25, 1890.

Friend F., your valuable fact reminds me that, when a boy, we discovered that tomato-juice would remove butternut stains and gummy matter from the hands. There must be a peculiar acid about the tomato that makes it a solvent for certain gums.—Your report in regard to buckwheat is only accidental.

WON'T HAVE TO FEED.

A drouth that lasted for seven weeks ended July 20th here; since then we have had plenty of rain, and the vegetation and flowers have returned like spring. Bees here have been doing nicely since the drouth. They have filled their brood-chambers to running over, and the supers have caught lots of it. I took off the supers that were full about a month ago, and supposed the season to be over as usual; but the bees refused to stop storing, and went up under the covers; and before I found them at it they had built several pounds of honey in some of the hives. I put the T supers on, and the bees seem to be happy. The honey this year is mixed with honey-dew, but the bees winter nicely on it here, and it will save feeding—a thing I have had to do for several years.

S. S. LAWING.

Henders m. Mo., Aug. 28, 1890.

Friend L., you also point a good moral. Keep an eye on your bees, and see what they are about; even if they haven't done a thing for weeks, they need watching all the same.

THE HOT WAVE IN CALIFORNIA.

In my last statistical report, dated July 25, I stated that the prospect for an average crop was excellent. The hot wave had then just reached us, but I did not at the time suspect its ultimate effect. A few days after, the honey-flow stopped; and although the alfalfa has been in bloom during the whole of August, not a pound has been stored since the first week of this month. The bees seem to be getting barely enough for their own use. My scales have lost a trifle in weight. The crop will, therefore, be considerably shorter than expected. Much of the honey is dark, presumably from buckwheat-brush, gathered between the first and second blooming of the alfalfa.

WM. MUTH-RASMUSSEN.

Independence, Cal., Aug. 29.

ITALIANS PULLING THROUGH WHERE BLACKS STARVE.

Many neighbors in the Osage River region lost nearly half their swarms (blacks) from starvation and moths during the July and August drouth. Now that smartweed (or ladyfinger) and Spanish needle are coming into bloom, the surviving swarms are doing well. The swarms lost were in old-fashioned box hives, without frames. The few swarms I have (Italians) in Simplicity hives, pulled through the drouth nicely on a local supply of late-blooming sumac and buckbush. They are just now making most of their honey from Japanese buckwheat bloom.

LEUCUS GOSS.

Connely, Mo., Sept. 1.

REPORTS DISCOURAGING.

HONEY CROP A FAILURE IN NEBRASKA.

The honey crop in this county is an entire failure. All bees here will have to be fed for winter. H. C. ALLEN.

Rising City, Neb., Aug. 9, 1890.

HONEY CROP WILL BE VERY SMALL.

The honey crop here is going to be very small, as the clover and basswood are gone, and no surplus up to this date. But little buckwheat raised around here. LEWIS H. KNUDSON.

St. Ansgar, Ia., Aug. 4.

ONLY 125 LBS. FROM 35 STOCKS.

Put me down among the Reports Discouraging—125 lbs. of honey from 35 stands, and some of them in poor shape for winter. I will not quit for one crop like that. It would take two or three like it. P. C. CHADWICK.

Loring, Kas., Sept. 7.

A POOR SEASON: 10 LBS. PER COLONY.

This has been a poor year for bees. They have not increased much, and some not any, and the honey is in about the same proportion. I think it will average 10 lbs. per colony, and the increase was about one in 10 all through the county. A. E. BRADFORD.

Hammond, Wis., Aug. 8.

BEES HAVE DONE POORLY ALL THE SEASON.

Bees have done poorly all the season, barely making a good living. They killed off their drones in June, and there was no swarming to amount to any thing. I had four colonies in the spring; and of these, two cast two swarms each, making four all told. Two haven't swarmed yet. W. J. McADAMS.

Western, Neb., Aug. 28.

POOR FOR IOWA.

This has been our poorest season for honey so far for four years. Since basswood, bees have hardly made a living. We have so far taken about 5 or 6 cwt. of comb and 45 gals. of extracted honey. But as the old adage says, "It is an ill wind that blows nobody good." What little honey there is will bring a better price.

E. R. A. BRAINARD.

Postville, Ia., Aug. 12, 1890.

POOR SEASON: RECORD OF SCALE HIVE.

This has been a poor season for bees in this section. I have a scale hive which gained, June 6 to July 16, 20 lbs.; July 16 to 26, it went back 5 lbs. Our only hope now is buckwheat, of which there is a great amount. The earliest pieces are already in full bloom. Not one swarm in ten threw off new ones. I wintered 18, and got only one. The new hives may be useful next year. L. M. CARPENTER.

Blooming Valley, Pa., July 27.

POOR CROP IN KANSAS.

GLEANINGS comes regularly, and I can say it does not come too often for me. I have received many good hints from it. It has been so dry in this part of Kansas this year that the bees will have hard work to lay by their winter stores. I have taken $4\frac{1}{2}$ lbs. of comb honey from one hive, and that is all I expect to get this year. The pound of bees and the queen we purchased of you in May are now a strong colony; and if it had been a good honey season we might have had two or three colonies more just as strong.

Burlingame, Kan.

ERNEST G. TERRY.

LAST YEAR, 3000 LBS.; THIS YEAR, ONLY 200 LBS. OF HONEY.

I had 3000 lbs. of honey last year, but this year it looked favorable in the spring up till the middle of June. Since then it has been very dry. I have taken only 200 lbs. so far.

Brighton, Ia., Aug. 9. W. A. SHAFNIT.

HONEY SEASON SHORT.

The summer honey season is over, and a very short one it was. I had 13 colonies, spring count, and have extracted 300 lbs., and increased to 28 by dividing. I haven't had a swarm this year. My bees are good and strong, and we hope to get a good fall crop. J. H. HILL.

Venice, Fla., Aug. 25.

POOR HONEY SEASON: BLACKS BETTER THAN ITALIANS.

This is a very poor honey season. Bees have not swarmed in some places, and have not even gone up into the upper hives. My blacks have done better than Italians this year. I noticed in June there was a great slaughter among the drones, which will teach us hereafter what the harvest will or ought to be.

Peosta, Ia., Aug. 6. MRS. J. H. ALLISON.

SHORT CROP, BUT 20 LBS. PER COLONY.

My sections came in time for the basswood flow, which was late. It commenced July 20th, and lasted for three weeks. The flow was very light, about 20 lbs. per colony. There was no surplus honey from clover in this vicinity this year. The prospect of a fall flow is good if the weather holds favorable. As there seems to be a shortage all over the country, those who have a little will probably receive a good price. FRANK DURAND.

Esdaile, Wis., Aug. 11.

CLOVER AND BASSWOOD POOR, BUT SUMAC GOOD: SCALE HIVE: $7\frac{1}{2}$ LBS. PER DAY.

The honey crop is rather light. There was and is the most white clover I ever saw, and the fewest bees on it. Basswood did not blossom much, and yielded scarcely any honey. The only plant that seemed to give a full crop was sumac, and $7\frac{1}{2}$ lbs. per day has been the best done by the swarm on the scales (extracting) this year. My best hive (Italian), which was run for comb honey, has filled 120 sections, $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{8}$. Another has filled 72, and are at work on 24 more, while about a dozen hives have done nothing in the sections. I have seen but 5 new swarms from my 50 hives. Buckwheat is in bloom, and bees are killing their drones. Too dry. C. G. DARLING.

Lincklaen, N. Y., Aug. 8.

EXPECTS TO FEED: BLACKS Dwindled WORSE THAN ITALIANS.

As our season for surplus is past, I send you a short report. Our honey crop is a total failure. We have taken only about 15 gallons of orange-blossom honey from 45 colonies, spring count, with an increase of about 50 per cent. Our colonies have dwindled very badly the past two months—blacks more than the Italians. Some stopped breeding altogether. No more blacks for me. I expect to have to feed all my colonies an average of 10 lbs. each to carry them over until October, when our fall flow comes. This is somewhat discouraging. But I have not lost my faith in the business. I am at work now getting out hives, supers, etc., preparing to start two out-apiaries another spring. I believe in having every thing ready before it is wanted. I have had some experience in this line the past season. ARTHUR F. BROWN.

Huntington, Fla., Aug. 8.

HONEY CROP EXCELLENT.

The honey crop is excellent in quality, and fair in quantity. From 54 stocks I have extracted about 2500 lbs. I have not had a large yield since 1878. Clover is a failure nearly every year, and basswood is largely cut off for lumber.

Kennedy, N. Y., Aug. 11. W. H. S. GROUT.

SEVIER CO., UTAH, A GOOD LOCALITY FOR BEES.

Our honey-flow commences about June 15th, and ends Sept. 15th. The average yield is about 150 lbs. of honey to each colony, and 100 per cent increase of bees. At times we have more increase of bees and less honey.

Elsinore, Utah, July 28. N. B. BALDWIN.

A BIG HONEY YIELD THIS SEASON IN TENNESSEE.

We have had a big honey yield this season. I find in some of my hives (and it has continued so for many months) many bees almost perfectly black, and others almost pure Italians, seemingly the progeny of the same queen. Is not this contrary to theory? JAMES A. LYON.

Clarksville, Tenn., Sept. 4.

No; hybrids are often marked that way.

A GOOD YIELD FROM BASSWOOD AND CLOVER.

In this locality my bees have had plenty of clover and basswood to work upon; four swarms have stored, in 2-lb. sections, 260 lbs. This I took off at the end of the basswood flow. They are now at work upon buckwheat. Only one increase from these four swarms.

Union City, Mich., Aug. 29. S. D. BUELL.

A SMALL CROP, BUT THE HONEY GOES OFF LIKE HOT CAKES.

This has not been an extra year in honey. Our crop was about 600 lbs. from 60 colonies, but some of them were so weak in the spring that they gave no surplus at all. It is beautiful honey, and goes off like hot cakes—no trouble to sell this year. We had only six or seven swarms. We do not expect to get any surplus this fall, as buckwheat will be a poor crop.

BELL L. DUNCAN.

Black Lick, Pa., Aug. 21.

MERCER'S SCALE-HIVE REPORT FOR 1890.

Inclosed you will find a report of my scale hive. This is the same one that was on the scales last year, with the same queen. It did not swarm, neither had it any help from any

other hive. After June 12 they continued to gather from ½ to 2 lbs. per day for about one

month. The hive weighed, when taken off the scales, July 20, 115 lbs. It is an ordinary 8-frame L. hive, with supers, each holding 7 frames.

L. E. MERCER.

Ventura, Cal., Sept. 2.

HONEY-FLOW GOOD.

The bees in this county nearly forgot to swarm this season. They were quite backward until the 15th of June, when they commenced to work. The honey-flow is good, but the bees are so cross we can hardly get along with them. If you can assign any reasons for their doing so when the pasture is good, I should be pleased to hear from you.

A. J. BELL.

Logan City, Utah, Aug. 13, 1890.

Friend B., the only reason I can give is, that the weather was cold, or else the pasturage was not very good.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

That art on which a thousand millions of men are dependent for their sustenance, and two hundred millions of men expend their daily toil, must be the most important of all—the parent and precursor of all other arts. In every country, then, and at every period, the investigation of the principles on which the rational practice of this art is founded ought to have commanded the principal attention of the greatest minds.

JAMES F. W. JOHNSTON.

USING CLOTH IN PLACE OF GLASS FOR HOT-BEDS, COLD-FRAMES, ETC.

A good many are making inquiries in regard to this matter, and they come to me, as I have had experience. At present we have only one bed covered with cloth; and if the money we have expended in cloth frames had been put in glass sash I should have been very much better pleased. They answer very well in the fall and spring to keep off frost, but for the snows of winter they do not answer at all. Suppose your cloth frames are covered with six inches of snow, converted into slush with a drenching rain. Under such circumstances the glass keeps its place all right, and is not harmed by the wet or dampness; but the cloth is soon made useless. Another thing, the cloth frames blow around unless fastened down, and this one thing has disgusted me with them. It is true, I might make them as heavy as one of the glass frames; but if I am going to do that, I think I should put in glass and have something substantial, and good for a lifetime, if properly taken care of. It is true, cloth frames are light to handle, and can be cheaply made, but they do not begin to keep out frost like tight, well-made sash. I have thought several times of having a cold-frame on the south side of some building, then have a cloth frame hinged on the north side, so it can be raised up and fastened against the building. This would keep it from blowing away, when they are down over the plants, or fastened up against the building, and might answer a very good purpose in the spring and fall.

One friend asks if there is any thing new that I have learned about greenhouses. Not much, unless it be this: We want a greenhouse so as to get every bit of sunshine possible. It should have a locality where neither trees nor buildings are going to obstruct the rays of the sun in the winter time. After we have secured every particle of sunshine possible, from sunrise to sunset, then I would make provision for securing the rains from above. Removing the sash, and letting the gentle rain come right down on the plants, is the best remedy that I know of for insects or disease. Besides this, if we wish

to push things in the winter time, of course we want to keep them warm. For this purpose I am rather inclined to steam-pipes. Somebody asks how flat it will do to have the glass. In hotbeds and cold-frames the sash are often so near level that there is only just incline enough for the water to run off. This is bad, however, late in the spring, when the sun comes nearly straight down, for the heat at noonday is tremendous if you forget to move the sash or open the ventilators. Houses running north and south, with pitch enough to the roof so the sun's rays can pretty nearly go straight through, morning and evening, give better results. In this case, when the heat is most intense about noon, the rays strike the glass at an angle. This equalizes the heat, giving us most of the sun's power morning and evening, and less at noon time. A more perfect arrangement would be to have one side of the house fronting the southeast, so the sun would shine straight through the glass, say at eight or nine o'clock in the morning; then have another side fronting the southwest, so as to have the same condition at three or four in the afternoon, and we should have it. Now, if these two sashes can be arranged so as to swing clear off against a couple of posts, to catch the rain whenever it comes, it would be my ideal of a greenhouse. A roof nearly flat saves glass; for the same number of square feet of glass will cover more square feet of plant-beds on a level, or nearly level, than any other way.

MOSS FOR PACKING PLANTS, COVERING SEEDS, ETC.

Friend Root:—If you are in want of moss, or should be any time in the future, write me for prices, as I think I can do better by you than heretofore; or I will refer you to other parties whom I have encouraged to gather a supply, thinking it would sell, thereby helping the party to add to his not over-large income. I have (of course) a desire to gather *money* when the opportunity offers, but I can be charitable only on a small scale, because of my circumstances; but I will do what I can.

Krumroy, O., Sept. 8. C. H. WELCH.

The above comes from a friend who furnishes us our moss for packing strawberry-plants, covering seeds, and other work in gardening. We purchased 40 barrels of him last spring, and it answers the purpose the best of any thing we ever got hold of. Now, my reasons for publishing the above letter are to call attention to the fact that this moss may be found in many swamps and marshes, and should be utilized. It has been advertised in some of our seed catalogues as high as 50 cents a peck. As it can, however, be compressed into a very small space, it seems hardly fair to sell it by the peck or bushel; and as it usually contains more or less moisture, it can not well be sold by the pound. I would suggest, however, that, in order to save transportation charges, it be dried in the sun. It may then be sent cheaply by mail, freight, or express. The purchaser can moisten it to his liking. A pound of perfectly dried moss will go a great way, and makes quite a bulk; but in order to let you see what it looks like, and to start a traffic, we will offer it until further notice, at 5 cents per lb. If wanted by mail, add 16 cents for postage. Very likely some one can undersell me. In fact, I should

like to see the price go down to a cent a pound or less. But in our competition we should be careful to send a good clean article. Some time ago I purchased several barrels of peat and moss from Barnegat Moss Co., Barnegat, N. J. It was raked up without any sifting or sorting, some of the barrels even containing sticks a foot long. I wrote them, remonstrating; but all the satisfaction I received was that they sent me just such as they sent to everybody else. I notice that Mr. E. L. Roser, of Britain, Summit Co., O., at the end of his strawberry circular, advertises it by the barrel for \$1.10. It is not only valuable to plant-raisers, but where it is very plentiful it is the nicest thing for bedding horses ever discovered, as it absorbs all the liquid manure, and the resulting compost is the nicest thing for greenhouses or plant-gardens that can be imagined. You can work it all up fine, and mix it with the dirt without any fermenting, or rotting at all. Our friend Eugene Davis, who gave us the Grand Rapids lettuce, says there is nothing better for raising lettuce in greenhouses than fresh horse manure broken up fine, and raked into the soil. Now to start this moss industry going, we will, in our next issue, give the names and addresses free of all those who are prepared to furnish dried moss at 5 cents per lb., and damp moss at a dollar a barrel, or less prices if they choose.

PLANTING STRAWBERRIES IN THE FALL.

Bro. Root:—One of your advertisers says: "Now is the time to set strawberries for next year's fruiting." Fiddlesticks! Everybody who makes a business of raising strawberries for market knows better than to set the plants in September for next year's crop; but those who have had no experience may be misled by such statements. Of course, if anybody wants to set a few plants in the garden by way of experiment, or simply for amusement or recreation, there is not much harm done; but it is not right, according to my way of thinking, to induce people to plant strawberries in the fall, with the expectation of marketing a paying crop the following season.

I could furnish you a nice lot of Haverland plants; but as my experience would not justify me in planting so late in the season, I will not sell any plants for fall planting, even if our honey crop is a total failure, and I must wear my old coat a year longer. S. P. YODER.

East Lewistown, O., Sept. 8.

Friend Y., you are, in the main, right. A person with little experience in strawberry culture certainly should not set out a very large extent of ground at *any* time of the year, unless he has some old hand to guide him. Of course, there may be exceptions, but this is the rule. Notwithstanding this, however, a skillful and experienced market-gardener can put out half an acre in August or even September, and get a partial crop next season. By the aid of the transplanting-tubes, if he has the plants on his own premises, or, say, if he can get them a few miles from his home, so he can go after them with a wagon, he can put them out in September or October, and have almost every

plant live. Of course, where we set out plants as late as October, they are to be treated as spring-set plants. The principal advantage will be, that you can do it oftentimes when you have more leisure. Another thing, there will then be no difficulty about getting in your plants early enough. We have put out strawberry-plants by taking up a lump of dirt with them, when we could not go to work in the morning because the ground was frozen. Toward noon it would soften up enough so that we could dig so as to put the plants in. These plants bore *some* fruit next year. I do not think we can too strongly emphasize the advice given, of starting small and enlarging as you acquire experience. The beginner will very soon know what he can do, without asking anybody. He should, however, avail himself as much as possible of the experience of others around him. But as soils, localities, and circumstances always differ, there is nothing like getting acquainted with your own surroundings. The earnest worker will soon get all these things under his thumb, as it were. We received 2500 Haverlands about ten days ago. Most of them were put in our plant-beds, about six inches apart. We shall not use them to fill orders until they have made new roots and new foliage, and are nice strong plants. The most of the plants that we are selling and putting up now are in lots of from 25 to 50. We get a few orders for a hundred; but the great bulk of our business in plants is for lots of ten—sometimes only five; that is, ten plants of each kind of all we raise, making forty in all. These, of course, are for garden culture, and probably few if any of our readers will make a failure in this line. Next season they will have plants of their own raising, to put in the field if they like.

Later.—Since the above was written, our boys have put out a strawberry-patch for my daughter, Mrs. Calvert, and another for my wife's sister, Mrs. Harrington. They were put out Saturday, Sept. 6. As I was very busy I did not superintend the work at all. The boys took them out of our plant-beds, and carried them across the road, and put them in mellow soil prepared according to my direction. They did not even use the transplanting-tubes. To-day, September 15, just nine days after, every plant out of the 600 (they had 300 apiece) is growing, and many of them are putting out runners. They look as fresh and bright, apparently, as those that have not been moved at all. Of course, we have had a very wet rainy spell; but such spells frequently happen in September. Now, these two strawberry-patches are going to bear a pretty good crop next season. I am sure of it, because I have had berries from plants set in September, more or less, every year for the past five or six years. One reason why we prefer to put out the plants in the fall is because we have much more time and ground to spare, and better facilities for putting the ground in excellent trim.

MOSS FROM THE SWAMPS FOR WINTER PACKING.

I send you a sample of moss. I have been using it for packing over my bees for three winters. I think it is a good material for that purpose. It is to be found here in Northern Iowa in quite large quantities in the sloughs, or "prairie ponds," and can be gathered in the fall of the year when very dry, and the water is all dried up from the ponds. It is found lying on the surface of the pond in a solid mat, I should say from two to four inches thick, and it can be gathered up with a pitchfork very easily. Understand, I have none of this moss to sell, but I think it could be gathered and shipped to dealers or to parties who wish to try it. This sample I send you is just as it grew on the pond, about two or three inches thick. It does not mold or mildew. I have some in my cellar, which I have had for three years, just as bright as it ever was. Bees have done poorly in this part of the country. I started this spring with 65 colonies. I got two swarms, but no surplus honey. It has been very dry this summer, but we have had plenty of rain of late.

Ackley, Ia., Sept. 5.

N. Young.

Friend Y., I feel sure the moss you send will answer splendidly. It was several years ago mentioned as being used for packing chaff hives. The sample you send is not exactly like what we use for packing strawberry-plants, but I think it would answer exactly for the purpose. See what friend Welch has to say on the preceding page.

THE BUSH LIMA BEANS, ETC.

At present we are selling shelled beans on our wagon as follows: White kidney, 5 cts. per pint; bush lima, 10 cts. per pint; and pole limas, 15 cts. per pint. There is not, however, quite so much difference as this in quality. The kidneys were put on the market long before the others, and people had become a little tired of them when the bush limas first came. Then they got a little tired of the bush limas, so that, when the great whoppers—the King of the Garden limas—came they were a novelty; besides, their enormous size made everybody want them. The bush limas are fully two weeks earlier than the pole limas. The Kumerle and Burpee's bush limas are none of them yet large enough for table use. I am inclined to think that the large bush limas will always be later than the pole limas (at least during a damp season, when they need more sun), and this is going to be rather against them. Our first bush limas brought 15 cts. per pint, but it was a pretty hard matter to sell many at that price. The King of the Garden has been selling at this figure for a week, all we could pick, and they never bring any back on the wagon. Had the ground not been so exceedingly wet, our Kumerles and Burpees would have been planted rather earlier. Last year the Kumerles were planted rather too early; but this year I fear I planted them rather too late. Although we have quite a little plot of Kumerles, I fear none of them will be mature enough to plant unless we pull the vines as we did last year, and let them ripen in the greenhouse.

SEEDS THAT CAN BE PLANTED IN SEPTEMBER IN THE OPEN GROUND.

First, cabbages, for setting in cold-frames later; Grand Rapids and Boston Market lettuce for the same purpose; winter onion-sets if you have not before; the same with spinach. In fact, it is a good plan to sow a lot of spinach once a week all through September. So much depends on the winter it will be hard to tell just what sowing will winter best.

OUR HOMES.

For I will give you a mouth of wisdom, which all your adversaries shall not be able to gainsay nor resist.—LUKE 21: 15.

A good deal has been said about the uncertainty of things pertaining to the life beyond. Unbelievers boldly challenge us to prove what we claim and believe; and as God has not seen fit to tell us very much about this unknown world beyond, we can not always answer their questions. In fact, I have often thought it just as well *not* to say very much. Then the question arises, "Have we, after all, any well-defined faith or sure grounds for believing there is a hereafter at all?" The text before us this rainy morning (at least it is a rainy morning here in Medina), however, gives us the promise that we shall be supplied with wisdom sufficient to answer all our adversaries, and that they shall not be able to gainsay nor resist the truth we shall be able to present to them. And now, dear friends, I have chosen this text for our talk to-day, because I feel that I have something in my possession that none of you will be able to gainsay nor resist. I do not mean in the way of argument, for it is too sacred and solemn a thing to argue about. But I feel in my heart that you will not *want* to gainsay nor resist what I have to present before you. Most of you are my personal friends; and even if you are not, I am sure you are open to reason and justice.

We have been having quite rainy weather. From reports, I judge that it has been rainy almost everywhere. We are so much in the habit of expecting a drouth during the last of August and first of September that it seems a little funny to find the ground so wet that one can scarcely step on it, and to long for sunshine as we often do in January and February. It has been raining more or less every day for a week; and after it rained steadily for so long, and we felt pretty sure that it was going to let up, it just turned in and rained harder and harder. I was up in the morning before it was quite daylight, as usual. Notwithstanding the rain, I looked over all the buildings, outdoors and in, to see if the water was doing any damage. Although we are up above low ground, we have had considerable trouble at different times by water coming into our basements; and in our efforts to carry the water away, sewer-pipes and tile have been laid so thickly under our grounds that one can hardly dig anywhere without striking them. In the progress of our new building, many of these old outlets for water are turned up; and as it was during the month of August, no one expected water enough to do harm, even if they were not just then properly connected again. Well, I went around into all the basements, and had the satisfaction of finding them all dry, sweet, and clean. No rush of waters pouring in greeted my ears or eyes. We have had in times past so much of this kind of work—water covering the basement floors, damaging goods, setting things floating, etc., and then leaving a disagreeable, damp, moldy, musty smell for weeks afterward that I had got pretty thoroughly roused up about it. As an illustration of some of my trials, let me relate a little circumstance.

I think it was in the month of June. After dinner my wife passed down through the wax-room and out through the machine-shop. A very heavy thunder-shower was under way, and she came rushing to me a good deal out of patience. She said the water was pouring into the door of the machine-shop like a small mill-race, and half a dozen men were standing

around, laughing to see it come in. I was down there in no time, and gave them some pretty sharp reproof about not stirring themselves when they saw the damage to property that was going on. Some of them excused themselves by saying that they did not work in that room—they were only passing through after dinner. Others said they did not know what to do.

"Here! follow me," said L. Shovels and pickax were right in sight. There had been some changes made in the railroad track in front of the door, allowing the water that came down the ditch to come straight into the door instead of following its accustomed channel. With my hands and such tools as I could grasp, hastily I commenced damming up the water. With three or four to assist me, in less than five minutes the water was stopped, and turned where it ought to go. Then with scoop-shovels and sawdust from the adjoining room we had the water removed. But the floor was soaked, and a good deal of water had got under it; and it is not at all strange, that, soon after, the Health Commission pronounced that apartment unwholesome. You can readily understand from the above why it is that I become pretty vehement when anybody by heedlessness lets water into any of the lower rooms. Please let us now go back to the morning in question.

I felt happy to think that every thing was safe and sound. I assisted in getting the market-wagon off, and then went to breakfast. After breakfast it began to rain still harder, and I discovered that a large reservoir we are making to supply a steam-pump for fire purposes had caved in on one side, and the outlet was stopped. When the workmen were digging the reservoir, I was assured that the water-conductor from the roof of the saw-room was securely fixed so as to carry away any water in case of rain. And not only was the outlet stopped, but the horses had evidently backed the wagon against this temporary water-pipe, and it was thrown out of place. The water from the roof of the large factory was pouring into the reservoir, endangering the walls that supported our steam-boilers. At such a time I generally fix my mind on some special man who knows how to do the work under consideration. My special man had not come, and, in fact, nobody was around who would be of any particular use in such an emergency. It wanted somebody with rubber boots and waterproof coat. I soon found one man to help me; but before the outlet was opened, the rain became so severe that it was filling up the cellar of the new building also. Finally, to my great relief, one of the men I wanted came around quite leisurely, asking me if there was something I wanted him to do. I felt provoked that he should ask such a question. But I kept the feeling down, and pleasantly told him what was wanted. Before the passage was fairly opened here, I found that the water was going into the basement of the *saw-room* building. It was the old story over again. A big stream was pouring in, and the baskets and other things were beginning to float about. I felt as if I could *not* have this floor soaked up with water again. I could not wait for rubber boots nor for rubber coat; in fact, I do not often have such things of my own, because I lend them to somebody before I have had them a week. I found a couple of men, and gave them some shovels, and told them to stop the water from going into the basement.

"Well, how shall we stop it?"

"Cut a little ditch hastily, and carry it along outside, instead of letting it run *toward* the building."

"But we can't make water run *up hill*," remarked one, by way of objection, while he stood still with his shovel, out in the rain.

"Yes, we *can* make water run up hill, if you will do exactly as I tell you," said I. Then the other one objected that it was all loose chips and sticks, and said the water would all run through it if used to make a dam. Oh! why couldn't these friends in this emergency, when the water was pouring into our basement, have a little more confidence in my wisdom and judgment? Why did they not reflect that I should never have had charge of all this property and these buildings had my judgment not been at least *tolerably* good? I did not say any thing, but went out and took hold of the tools myself, and showed the one who said that water would not run up hill, that, by raising the embankment high enough, we could make it fill the depression and go over the higher parts. The one who said sticks and chips would not stop water was directed to take some soft mud out of the road and plaster the sticks and chips until they would hold water. Mud was in great plenty, and as soft as butter; and it did not take two minutes to "butter" over the porous material so it carried water nicely, and in five minutes more we had a big muddy stream going off beyond the building to a place of safety. How much can be done with a hoe and spade and shovel, in a crisis like this, if you only have a man who is expert in their use! I love tools; and I especially love hoes and spades and shovels. I love the man who is expert in their use; and I have sometimes felt like raising my hat in respect to the man who knows how to handle and is an expert with a spade. Why, the minute he takes hold of one I can tell whether or not he knows what a spade is for. I ran down into the basement, and was rejoiced to see the water had every bit stopped. Then we rushed over to the new building, and found the same state of affairs there. The water was going down the open hatchway like a small millrace. I called for some more hands to make a dam and carry it off. It was just as before—they stood out in the rain and objected, not doing any thing until I grasped the hoe and showed them how. One man said we should have to dig down *three feet* to keep the water from running into the building. I presume they forgot I had played with water almost all my life, and that I had watched irrigating ditches along the sides of the mountains in California and Arizona with an intense interest that ordinary people know but little about. I know pretty well what can be done with water. In less than one minute a great part of the flood that was going into the hatchway was turned off over the ground. Of course, it very quickly made a little pond there; but that was a better place for a little pond than around the foundation stones of the new building. In fact, the water was a foot deep there already. The rain was so great that the ordinary outlets were insufficient, especially while shavings and sticks were obstructing them. Well, before this little pond had got over its environments, back to the building again, a little ditch was hastily made where it seemed most inclined to break over, and in ten minutes we got it away from the building, and in no spot did we dig more than six inches. The outlet of the reservoir had by this time caved in again, and that was rapidly filling. The man who opened it the first time, and who knew just how, could not be found, so another one had to be instructed where to find the tile, and how to manage so as to prevent the mud from being washed into it. Just then I remembered the printers were on the last page of the strawberry book, and, in fact, it was already on the press. I had been in the office once or twice to see about it; but owing to the excessive rain, nobody had yet come around to whom I could give orders. When I did remem-

ber it, it worried me a little. Sure enough, in some way the impression had got out that I was through with my corrections, and it was in the press, and several hundred impressions had been run off. I had kept level until about this time, and then I fear I scolded some. There was nothing amiss, however, except some omissions in a part of the index; and if you find that a part of it is a little out of "whack," as some friend expressed it, you will know how it came about. The press was stopped, and I sat down to finish the page where I left off the night before. The water was dripping from me all over, and running away down into my shoes. In fact, my hat was so soaked that the water kept running down my cheeks and running from the end of my nose on to the strawberry book I was trying to read, until I pulled my hat off, and then the draft was too severe on my bald head. I got the page finished, however, and went back to look after the water. One of the men I wanted could not be found anywhere. At last he turned up away down across the creek, letting the water off from the *celery*. When asked how he came to go off there, he said it was because I told him to. After we got the water stopped from going into the basement, I told him to help let the water off from the *cellar* of the new building. I suppose I stopped at the word "cellar," so many things were crowding me all at once, and he said he understood me to say "*celery*," and so put away off to the creek bottom (with his rubber boots and coat), where almost the whole ground was submerged. If there is any thing that will bear unlimited quantities of water without injury, it is *celery*.

I have for some months rather held back and objected to the new improvements that have been started. I wanted to have the new building put off till another year. The reservoir, with its attendant steam-pump, I objected to also. One reason why I objected to it was, I knew it must bring added responsibilities which I did not feel able to bear. But the boys, in their enthusiasm, explained that these things were urgently needed, and will be an excellent investment. If we are going to have them, the sooner the better. They propose to take the responsibility off from my shoulders—at least a part of it, and look after things. I presume this rainy morning must have been a good time to sleep—at least, nobody seemed to be in much haste in getting around, and it is not to be wondered at that I became a little cross and impatient. I did not say much out loud, but I declared mentally that things had got to come to a standstill until we could get ready to do every thing "decently and in order." (The last is Bible teaching, but you know Satan can quote Bible tiptop.) I did not realize that I was getting into a bad and unchristianlike frame of mind. A little incident, however, reminded me of it. Somebody came along quite leisurely, and pleasantly wished me a good-morning. Now, just at that time the "good-morning" did not hit me just right. Wet and dripping as I was, and tired out, it seemed to me that there was no time for "good-mornings." I answered back pleasantly, because I knew it was my duty. But—shall I dare tell you what was in my mind? I think I will, that you may get a glimpse of the battles that your old friend has to fight. Instead of saying good-morning back to him as is every Christian's duty, no matter what is under the surface, Satan (I think it was) suggested that it would give me rare pleasure to throw a club at his head. I shouldn't want a very big club. I think, but I felt just spiteful enough at everybody and every thing, especially those who looked smiling and happy. Perhaps some of you begin to inquire, "Why,

Bro. Root, where was that little prayer of yours—that warning note that you tell us comes to remind you that danger is near?”

Well, it did come just about then, and it was needed, and I prayed earnestly to be lifted from the slough of despond into which I seemed to be sinking; and it was the answer to this simple prayer—a quick swift answer—that has prompted me to tell you all I have been telling you this morning. You see, I had got into a way of thinking that I was an abused and injured individual. Were you ever there, my friend? And I was saying mentally that I was not going to bear everybody's burdens *any longer*; and the answer seemed to be a reply or rebuke or reproof to this attitude of heart. It came in the line of a couplet of the hymn I have been singing so much of the time during the past two weeks. You will find the hymn on page 647 of our last issue. Here are the two lines that Christ Jesus held up to me.

I'll bear the *toil*, endure the *pain*,¹
Supported by thy word.

Come to think of it, there *had* been considerable “toil,” but not much pain; and then I remembered to thank God, not only for energy, but for strength and endurance to stand such a wetting without injury. Some of you may say that such a wetting is dangerous. No, it is not—at least not to A. I. Root. If I do not get chilly after getting wet, it does not hurt me a particle. The last words of the lines, “Supported by thy word,” seemed to suggest something just then; and then my thoughts ran in line with the Savior's work here on earth; and that old favorite text of mine that has been music in my ears for so long came out sharp and clear, “Not to be ministered unto, but to *minister*.” Why, it is worth all my experience that morning to have such a bright and vivid practical application of this wonderfully inspiring text, to the true, faithful follower of Christ Jesus. I was out of the mud and miry clay in no time—that is, I was out spiritually. My feet were still in my mud-soaked shoes, and the water was soaking through my hat, saturating the few gray hairs that remain. Drops of water were still on my nose and clothing, but what did it matter? Christ's promises were ringing through my soul, and a great happiness came over me. I took up my old hymn, and it never sounded so sweet before—“Am I a soldier of the cross?” I felt glad that I could answer that I *was* (or at least trying to be), and that I had just withdrawn from a hand-to-hand conflict; and then came the words, “Must I be carried to the skies on flowery beds of ease?” I answered at once, “No, no. Let me rather *‘bear the toil’* and *‘endure the pain,’* if, by so doing, I can feel the Master's presence by my side, and my hand in his.” “Are there no foes for me to face?” Well, I think there are a *few*—at least, judging from past experience. “Must I not stem the flood?” Well, well. We *had* stemmed one “flood” unitedly, and had come off victorious; and A. I. Root all by himself stemmed another little flood, and he, too, came off victorious, and is now rejoicing.

A word about catching cold. Dear friends, I never catch cold or come to harm of any kind when the blood is coursing through my veins stirred by the enthusiasm of love for Christ Jesus and humanity in general. When I went over at 11 o'clock to take my usual nap I did fear the consequences of lying down with my clothing so damp; therefore I put my feet into the oven just a minute. My wife says she is sure I did not have them there more than *half* a minute. Then I slept half an hour, and awoke rested, well, and happy.

We were planning to get off the strawberry book that day; and it seems to me, as I look

back, that I never saw work go along so rapidly and pleasantly before. I told them we wanted a certain number before 3 o'clock. I presume I looked pleasant and happy, and I guess the spirit in my heart must have been contagious, for everybody seemed to catch the spirit of enthusiasm in getting the books mailed. It did not occur to me that any of the friends around me cared particularly for a book on strawberries, and I was greatly pleased when the foreman asked how much I would charge them if all the printers clubbed together and took one apiece. I looked up in astonishment. Said I, “Why, bless your hearts, boys, if you will read the book through you shall all have one without cost, with the compliments of the author and publisher.” Pretty soon the office girls heard of it, and wanted to know if they were included; and it gave me additional pleasure, not only to supply them on the same terms, but every one else in my employ.

I have sometimes thought that these texts that burst suddenly upon us, or the memory of these old hymns, braces up the Christian something like martial music in a battle. I have heard that, when an army was demoralized, and the foe fast gaining the ascendancy, the sound of the drum and fife, with some familiar inspiring air, would of itself rally the demoralized forces, and give new courage to the soldiers, to such an extent that they would turn round and gain a victory, even when, to all appearance, the cause was hopelessly lost. Now, the Bible promises, and these old hymns that have been almost a battle-cry against evil for ages past, operate in just the same way. Only a few hours before, I felt like throwing a club at the one who bade me good-morning. What a change just the little text and the lines of the hymn had brought! The events of the morning had been only a wholesome school or drill to me. After I had come out victorious over a wrong spirit, it seemed as if the dear Savior delighted to pour out his spirit upon my soul in a way he had never done before. As I passed around from one to another of my helpers, they never looked so good and so lovable as they did then. First I inwardly thanked God for giving me a certain one to be a companion and a helper. Then I discovered that his next neighbor had also grand and noble qualities; and so on it went from one to another, all over the establishment. Even old Charlie, who draws the market-wagon, by the light of the new joy that was filling my soul seemed a grand, good old faithful servant, notwithstanding some of his notions and queer ways. I told my wife that such joy and peace and thankfulness seemed *too good* for any human being, and it almost made me tremble to think that I should probably lose it very soon by some foolish act. I could not but remember the lines:

O Beulah land, sweet Beulah land,
As on thy highest mount I stand,
I look away across the sea,
Where mansions are prepared for me,
And view the shining glory shore,
My heaven, my home for evermore.

And then that last verse:

The zephyrs seem to float to me
Sweet sounds of heaven's melody,
As angels, with the white-robed throng,
Join in the sweet redemption song.

Well, dear friends, I did stand on the “mount” for nearly two whole days; but I came down with a tumble finally. It was not a very big tumble, however, and I soon clambered back pretty nearly but not quite where I had been. I presume it is not well for us to stand away up entirely clear of Satan's clutches *all* the time. If we did, we might lose charity for those who are tempted and fall, worse than *we*

do. Once in a while the dear Savior thinks best to let us catch a little glimpse of heaven through the clouds, and then he bids us go back to earth to bear the *toil* and endure the *pain*. And now, dear friends, to the point of our text:

This world is full of those who are tempted sorely, and tried sorely. Almost every one whose eyes rest on these pages, especially if he has tried to be a Christian, will remember just such conflicts by the score, as I have told you about to-day. Our daughter Constance, or "Blue Eyes," as I have called her, took the train last evening to go away for the first time in her life from the parental roof. She has gone to Oberlin to school. The first number of *GLEANINGS* that ever saw the light, came from the press on her first birthday. She is almost 18 years old, and so is *GLEANINGS*. We feel very anxious that she should go through college and finish her education. In many respects she is like her father, and will have the same kind of battles to fight. I fear, however, she is a little more prone to give up and become discouraged. Now, what will help her? What will be the most helpful to any poor soul when it comes to bear life's struggles, and to fight life's battles? Why, there is nothing in the whole wide universe like the religion of Christ Jesus. There is nothing at all to compare with it. Think of the text, "Not to be ministered unto, but to minister," to pin to your banner when you need help, and then the words of the old hymn right in the same line, "I'll bear the toil, endure the pain." It is not only boys and girls who become discouraged and give up, but it is grown-up men and women. It is not only those who are struggling against poverty, but those who have their *thousands* have the same battles to fight. Somebody has said that prosperity is harder to bear than poverty. *Suicides* are occurring constantly. Look at the papers. Human beings, with God-given powers and great gifts and capabilities, are giving way to evil passions, and going down to shame and ruin. What is there to be compared with the religion of Christ Jesus to help one to bear up? Have you a friend, a brother or sister, or son or daughter away from home, battling with life's dangers? What would you *give*, my friend, to know that this loved one, this relative, was at this moment holding fast to some Bible text like the ones I have quoted, or gaining new courage from some old hymn that bids him—nay, inspires him—to fight on, as a humble soldier of the cross?

May God bless the words of my text to-day; and may the divine influences of his Holy Spirit help to make my meaning clear. And may the grand and glorious thought (which I have *tried* to give you in my poor way) come home to *your* heart in such a way that not all the adversaries of Christ Jesus (with Satan *himself* included) shall be "able to gainsay nor resist" the great truths—truths to be found only in that book that tells us of Him who came to *minister* and *not* to be ministered unto.

EDITORIAL.

Whosoever will be chief among you, let him be your servant.
—MATT. 20: 27.

GLEANINGS ENLARGED.

WE find, upon changing our body type for *GLEANINGS*, that we have not only enlarged the face of the type, but actually added nearly one-fourth to the amount of reading-matter, without adding to the amount of paper. This seems

like a paradox; but the gain is made from the fact that the new type is set more compact.

A GOOD HONEY-YIELD IN CALIFORNIA.

ON page 679 we have a report of a hive on scales. It seems this season our California friends have had a continuous flow of honey from the middle of April till about the middle of July; and at one time the amount reached the nice record of 18 lbs. in a day. If all this great yield is equal to the sample sent us by friend Mercer, he ought to be a happy man. A carload of the same kind is now on the way from Ventura to Medina.

LOSS, DAMAGE, AND MISCARRIAGE BY RAILROAD AND EXPRESS COMPANIES—WHO IS RESPONSIBLE?

DURING the past season there has been much trouble, first and last, in the above line; and quite a few with whom we have deal insist that we shall bear *all* responsibility. In consequence of this we have been obliged to have printed on our invoice sheets the following:

Our responsibility ceases when goods are received for in good order by the railroad or express company.

We do not mean by the above that we are unwilling to make every possible effort to look up lost goods, or have damages collected in case the goods can not be found. But we mean this: We can not send the money back, even if the goods should be weeks or months on the way. I know there are some kinds of business where it is possible to guarantee safe delivery. Some seedsmen do this; but seeds are usually small in bulk and light in weight; and when a seedsman says he will take all risks of all kinds, he usually has a profit that will enable him to do so. With our business, however, it is different; for we sometimes sell honey at a profit of only half a cent a pound. In this case there is no margin for us to take responsibilities that do not belong to us. If the goods are delayed because of any blunder of ours in directing them, or because they were poorly packed or poorly made, then, of course, we must stand the consequences (whether we can afford it or not); but to attempt to shoulder and make good all the results of carelessness and inefficient work with the great transportation companies of the world, does not belong to us. Now, quite a few worry and borrow trouble needlessly when goods do not come to hand promptly, taking it for granted that their money is all lost and gone. Everybody should know that all transportation companies are responsible. If they lose your goods, or smash them by their own carelessness, they must make it good. The laws of our land insist on it; and if the companies do not do that, they will have to stop doing business. The most annoying thing about it, however, is that they are permitted to take their own time. Sometimes it takes us a whole year or even more to get pay for lost goods; and on this ac-

count we frequently tell our friends who are suffering for the need of something that does not turn up, that we will fill the order again, and send more goods right on, providing the consignee will agree to take both shipments if both should come to hand. Express companies are liable for unreasonable delay in delivering goods; and I suppose that railroad companies are also liable to some extent for every unreasonable delay. Now, if the position we take is in any respect unfair or unchristianlike, I stand ready to be set right.

SPECIAL NOTICES.

PRICE OF BEES AND QUEENS.

The price advances in October to July prices. Un-
tested will then be \$1.00; tested, \$2.00; select tested,
\$3.00. We ran out of imported queens within the
last few days, but are daily expecting a fresh im-
portation. Prices will be four, five, and six dollars
respectively. *Later.*—Imported queens are here.

HONEY JUMBLES AND CAKES.

We have just sold to a large bakery the off grades
of honey received from Arizona, to be used in mak-
ing honey cakes and jumbles; and we take some of
these in exchange for the honey. We learn that this
bakery alone is using about 4 bbls. of honey daily
for honey cookies, and they are having such a big
trade they are running night and day, and still be-
hind on orders. If any of our readers have any off
grades of honey that don't find ready market at a
fair price, please send us a small sample, naming the
quantity you have, and how it is put up, and the
least you will take for it. We will try to find you a
market. The honey jumbles are the same that we
sold two or three years ago, and are worth \$2.00 a
box of about 14 lbs. Any less quantity will be 20 cts.
per lb. The honey cakes have only about half the
quantity of honey in them, and are sugar-coated.
Price \$1.50 per box, or 15 cts. per lb. for a less quan-
tity. We will mail a sample package of either, put
up in a sample pasteboard box or section carton,
postpaid, for 10 cents.

PLANTS THAT MAY BE PUT OUT IN THE FALL.

During the last of September and first of October
is an excellent time to set out a good many kinds of
plants. Asparagus will do nicely. Raspberries,
blackberries, and currants, will also get well settled
for winter. If the soil is very heavy clay, it may
be best to mulch them to prevent the frost from
throwing them out. Last, but not least, I would put
out a few of such kinds of strawberries as I wished
to test. The strawberry is peculiar, inasmuch as you
can force it just as late in the fall as you please, by
cultivation and manure; and no matter how sudden
severe weather sets in, it does not seem to harm it at
all. I have never seen any harm to strawberries
from severe winters unless it is the heaving out by
the frost, and this seldom happens with plants that
get well rooted. Judicious mulching will prevent it
entirely. In consequence of the recent heavy rains,
we have had an abundant supply of the plants we
have advertised, and we can also furnish, in limited
quantities, to those who may wish to test them, the
Crescent, Cumberland, Louisa, Belmont, Miami, and
Sharpless. The price of all strawberries from this
time until further notice will be 15 cts. for 10, or 75
cts. for 100; if wanted by mail, add 5c for 10, or 25c
per 100. Jessie, Bubach, Haverland, and Gandy,
we expect to be able to supply all demand for until
the ground freezes so as to hold them fast. The oth-
ers will not last very long.

WHITE COMB HONEY FROM MATTHIAS SCHNEIDER, JR.

The comb honey mentioned in this department in
last number of GLEANINGS, reached us just three
days ago, as we write this, and to-day we are ship-
ping the last pound of it, and haven't enough to fill
orders. We don't see any prospect of having more
in stock for two or three weeks, although we may
get some before that time. This honey from Mr.
Schneider is about the whitest honey we ever saw,

and it came in the best shape of any shipment we
ever received. I believe there was not a case leak-
ing in the whole lot of over 3000 lbs.; and the secret
is, it was crated up in crates of about 200 lbs. weight,
with handles projecting from each end to carry it
by. Nine 24-lb. cases, or 18 12-lb., were put into a
crate which consists simply of a frame of pieces $\frac{3}{4}$
by 3 or 4 inches. In the bottom of the crate the
cross-pieces running the shortest way are on the out-
side, and on top of these are some thin boards nailed
between the outside strips, making the bottom
nearly tight. On this is spread straw from one to two
inches deep for the cases to rest on and receive the
jar if the crate should be dropped. A similar meth-
od of crating honey was described by J. A. Green,
May 1st No., first article. It seems to have proven
such a great success wherever tried that we would
advise bee-keepers not to ship any more honey to
market in small quantities without putting it up in
similar crates. You will save, in better price re-
ceived for honey, a good many times the cost of
these crates.

W. H. LAWS, Lavaca, Ark.

POTATO-BOXES

GALVANIZED BOUND.

(TERRY'S).

These are made of
basswood, bound with
galvanized iron. The
galvanized iron gives
strength, and the
basswood strength
and lightness. These
hold exactly a bushel
when level full, and
may be piled one on
top of another. Al-

though they are made especially for potatoes, they
can be used for fruit, vegetables, picking up stones
on the farm, and a thousand other purposes. When
piled one above the other, they protect the contents
from the sun and rain; and from their shape a
great many more bushels can be set into a wagon
than where baskets are used. They are also much
more substantial than baskets.

Price, nailed up, 25 c each; 10, \$2.25; 100, \$20.00.

In the flat, including nails and galvanized iron,
Per pkg. of 1 doz., 2 nailed and 10 packed inside,
\$2.10; 10 pkgs., 5 per cent off.

SLATTED POTATO-BOX

As the pieces of
which the above
are made are
mostly from re-
mnants of basswood
used in making
sections, we can
furnish them nailed
up for 20 cents
each; 10 for \$1.85;
100, \$16.00. Materi-
al in the flat, in-
cluding nails, in
packages of 12
boxes each, at

\$1.50 per package, and each package includes two of
the 12 boxes nailed up, complete. Ten pkgs., 5% off.

Please be careful in ordering to say whether you
want the *galvanized bound* or the *slatted* boxes.

A. I. ROOT, Medina, Ohio.

LITHOGRAPH LABELS

In 12 Colors, at \$2.00 per 1000.

The 12 colors are all on each label. They are ob-
long in shape, measuring $2\frac{1}{2}$ x2. They are about
the nicest labels we ever saw for glass tumblers,
pails, and small packages of honey. We will mail
a sample, inclosed in our label catalogue, free on
application, and will furnish them postpaid at the
following prices: 5 cts. for 10; 35 cts. for 100; \$1.20
for 500; \$2.00 for 1000. A. I. ROOT, Medina, O.

Kind Friends!

I have now caught up from my delay caused by my illness. If weather permits, I shall have a few more queens for sale. I now have almost full control of the drones; others all dead; guarantee every queen mated to Italian drones. Drop me a card, telling me how many you can use, and pay on arrival of queens. Only untested and virgins, \$1.00 and 50 cts. each. Write quick. I will not promise to send one, therefore I do not ask pay in advance.

JACOB T. TIMPE,

CONVENTION NOTICE.

The Missouri State Bee-Keepers' Association will meet in convention at Mexico, Mo., Oct. 22 and 23. A good programme, and an instructive and interesting time is expected. All persons interested in bee culture are cordially invited to attend. Board can be obtained for 75 cts. per day, or 20 cts. per meal.

J. W. ROUSE, Sec., Mexico, Mo.

KIND WORDS FROM OUR CUSTOMERS.

WHAT THEY SAY OF THE A B C OF STRAWBERRY CULTURE.

It is an excellent little manual.

H. GEO. COMEY, Ed. Orchard and Garden.
Little Silver, N. J., Sept. 22.

The *New England Farmer* of this week says:

The book contains a vast amount of practical information, being just exactly what is needed, and all that should have large sales.

It adds another to the valuable works that you are publishing, and is a nice work, full of information, worth many times the money asked for it.
Hamilton, Ill., Sept. 18. DADANT & SON.

I like the work so much that I propose to print almost no introduction in my catalogues hereafter, but refer my customers to your book—or Mr. Terry's—to find out how to grow strawberries.
Cuyahoga Falls, O., Sept. 15. M. CRAWFORD.

My strawberry-fever burned out some years ago, and you know it is not easy to communicate such ailments the second time; but I enjoy the interesting little book all the same. EMERSON E. HASTY.
Richards, O., Sept. 18, 1890.

We have not a great many works on the strawberry; and having had a good deal of practical experience in growing strawberries for family use and the market we do not hesitate to recommend the recent work, "A B C of Strawberry Culture," by T. B. Terry and A. I. Root. The volume is handsomely bound, and contains 150 pages attractively illustrated.—*Tennessee Farmer*.

"A B C of Strawberry Culture" is the title of a neat little book of 148 pages which contains the experiences of T. B. Terry and A. I. Root, in the pleasant and profitable work of growing this popular fruit, the strawberry. Those who are acquainted with Mr. Terry's success in this branch of horticulture will wish the book; and those who are not, should get the book to find out how he attained his success.—*Fruit, Field, and Stockman*.

OUR STRAWBERRY-PLANTS.

The plants arrived on the 20th in good condition. I have never before seen such good roots on young plants.
Medford, N. J., Sept. 22. E. A. TAYLOR.

I received the strawberry-plants in splendid order. We had three days of rain on them, and not one of 1200 wilted.
Clifford, Ind., Sept. 13, 1890. W. H. BUTLER.

The strawberry-plants came O. K., and are as fine as I ever saw, and very nicely packed. As I unwrapped them it seemed to me as though I could almost taste their fruit, and that night I dreamed of eating strawberry shortcake. G. W. DAVIS.
Pine Creek, Mich., Sept. 8.

The queen-cages are exceedingly nice, and show what nice work can be done with accurate machinery.
Morgan, Ky., Aug. 25. J. P. MOORE.

DOVETAILED HIVE; BEST SECTION-HOLDER A SUCCESS.

I consider your Dovetailed hive the best and most convenient one I ever used. I bought some from Mr. J. D. West, that he got of you last spring. The sections come out of the supers the easiest of any I
R. W. HIGINBOTHAM.

Morris X Roads, Pa., Sept. 1.

Goods received O. K. I am well pleased with them all.
L. J. STARK.

Harris, Minn., Sept. 2, 1890.

I want your valuable journal continued as long as it retains its present tone and usefulness. I differ with you denominationally, but we will meet all true followers of the one Christ over there, I hope.
Phalia, Miss. F. GENTRY.

OUR SOLAR WAX-EXTRACTOR.

The solar wax-extractor, bought of you this spring by T. G. Newman is a perfect success in every particular. It just does the work nicely.

DeKalb, Ill., June 18. A. Y. BALDWIN.

ALFALFA HONEY.

Our alfalfa honey came in splendid order, and is pronounced excellent. I was very curious to taste alfalfa, and glad when I found the shipment was of it. Now I am delighted with it, and prefer it to white clover for my own use. That peculiar flavor is delicious.
Mrs. JAS. M. DAVIS.

Ligonier, Pa., Aug. 26.

MORE ADVERTISING THAT PAID.

During the last few days, orders came in so heavy that I found I should be all out, but did not realize it in time to write you sooner. I can not fill a third of the orders I am now receiving from my advertisement.
D. G. EDMISTON.

Adrian, Mich., Sept. 13.

ARRIVED IN SPLENDID SHAPE.

The queen came to hand in splendid shape, lively as a cricket, and I have got her in the hive in good shape.
GEO. A. GOULD.

Marshfield, Oreg., July 5.

THE CANDY PLAN A SUCCESS.

The queen I sent for some time ago came to hand in good shape, and was safely introduced by the candy plan. Thanks for sending such a fine one.

Alliance, O., Sept. 1. CURTIS E. BOWMAN.

THE TESTED AND UNTESTED QUEEN.

The tested queen shipped Sept. 5 came all right, and she is in the hive safe. She is a beauty. You sent me one untested queen in July. I placed her in a hive that was nearly destroyed by worms, and I have now the finest hive of bees I ever saw in my life.
C. W. HUFFMAN.

Richwood, O., Sept. 15.

A GOOD TESTIMONIAL FOR BINGHAM SMOKERS.

The Bingham smokers I received last year, as well as the soldering-iron and grindstone, have been very satisfactory. The smoker has done very much in the line of quieting the bees, and I would not be without one of the Bingham's, since I tried them. Frank Benton told me, years ago, about their excellence, but I did not think so very much of it till I tried it myself. I handed one over to my brother, and worked with one myself. The smoker is working well; but I am afraid our Arabs have not allowed the most careful hands; they might get spoiled, so I had better have a few on hand.

PH. J. BALDENSPERGER.

Jaffa, Palestine, Aug. 21, 1890.

FURTHER PARTICULARS FROM W. S. HART'S APIARY.

I was greatly surprised to find the engraving of my photograph, sent you a short time ago. I sent it, as I thought it quite a pretty picture, and one that would interest you. I am pleased to have it in GLEANINGS, and especially so since it is so excellently well done. I am not an expert judge of such work, but it seems to me that it is one of the best engravings that I ever saw. The hives, as you suggest, though not the Simplicity, are much like them; and when making my first one I embodied a good many features of that hive. I claim no merit for my hive over the Simplicity, except that it was a little easier for me to construct with the tools at hand. It takes the L. frame, the best of all for extracted-honey production in this State. The ground is kept clean under the trees and about the hives, only by the vigorous use of the hoe every little while through the summer. Vegetation grows rank in the summer, but in the winter the ground will remain quite clean for weeks after a hoeing.

Bradford, N. H., Sept. 8. W. S. HART.

HONEY COLUMN.

CITY MARKETS.

ALBANY.—Honey.—We have received up to date, 463 cases of comb and 40 packages of extracted honey. Fancy clover continues scarce, and we have made sales of 1-lb. sections as high as 18 cts. Medium grade clover sells at 14@16c. Buckwheat, 1-lb. sections, 12@13; 1½ to 2 lb. sections, 10@12. We never knew the demand so good for extracted at this early date. We quote 7@10.

CHAS. McCULLOCH & Co.,
339 Broadway, Albany, N. Y.

Sept. 20.

KANSAS CITY.—Honey.—The demand for comb honey still continues good, and the supply still continues light. We quote choice white 1-lb. sections at 16@18; choice light, 1-lb. comb at 14@16; dark, 10@12. Extracted, white, 6@7; dark, 5@6.—*Beeswax*, 25.

CLEMONS, MASON & Co.,
Kansas City, Mo.

Sept. 20.

CINCINNATI.—Honey.—There is a good demand for all kinds of honey. Arrivals are fair. We quote choice comb honey at 14@16 in the jobbing way. Extracted, 5½@8 on arrival. *Beeswax* is in good demand at 24@26 on arrival, for good to choice yellow.

Sept. 22.

CHAS. F. MUTH,
Cincinnati, Ohio.

ST. LOUIS.—Honey.—There is no appreciable change in the market. Comb is scarce, with good demand; but it must be light to bring top prices. We are very nearly cleaned out of extracted. *Beeswax*, prime, 27.

D. G. TUTT GRO. Co.,
St. Louis, Mo.

Sept. 19.

COLUMBUS.—Honey.—Comb honey selling at 18 cts. for choice white clover. Market is active, and well cleaned up. All shipments of choice goods meet with ready sale.

EARLE CLICKINGER,
Columbus, Ohio.

Sept. 18.

BOSTON.—Honey.—We quote best white clover, 1-lb. sections, 17@18; 2-lb., 15@16. Extracted, 7½@9. No *beeswax* on hand.

BLAKE & RIPLEY,
Boston, Mass.

Sept. 20.

DETROIT.—Honey.—There is no white comb honey in the market, and fall honey is selling at 13@14c. Extracted, 7@8.—*Beeswax*, 26@27.

Sept. 19.

Bell Branch, Mich.,
M. H. HUNT.

NEW YORK.—Honey.—Fancy white, in 1-lb. sections, 17@18; fair to good, 14@17; fancy, 2-lb., 14@15; fair to good, 13@14; fancy buckwheat, 1-lb., 12@13; 2-lb., 10@11. Extracted, white clover, 8½@9; buckwheat, 6½@7.

Sept. 10.

CHAS. ISRAEL & BRO.,
110 Hudson St., N. Y.

FOR SALE.—5000 lbs. well-ripened extracted honey, in 60-lb. cans. C. H. STORDOCK, Durand, Ill. 18-23db

FOR SALE.—1200 lbs. extracted clover honey, in 60-lb. cans, at 10 cts. here.

R. H. BAILEY, Box 81, Ausable Forks, N. Y.

FOR SALE.—400 lbs. choice white-clover honey in 1-lb. sections; will pack in 24-lb. cases, crated to suit purchaser. I want 16 cts.; delivered at R. R.

WM. VAN AUKEN, Woodville, Jefferson Co., N. Y.

FOR SALE.—1000 lbs. white alfalfa comb honey, in 12-lb. cases, at 16c per lb.; also 400 lbs. extracted, very fine, in 75-lb. cans, at 10c per lb.

J. T. CLAPP, Supt. Denver Land Co.,
Broomfield, Boulder Co., Colo.

19-22db

FOR SALE.—1000 lbs. of buckwheat comb honey, in 1-lb. sections.

D. F. LASHIER,
Hooper, Broome Co., N. Y.

19-20d

FOR SALE.—50 one-gal. tin cans of white clover extracted honey; very fine and white, beginning to granulate some. I want 10 cts. per lb. here

G. L. JONES, Grand Ridge, LaSalle Co., Ill.

FOR SALE.—25 000 lbs. of the very finest honey, in scant 1-lb. sections; put up in white basswood cases, holding 12 sections. A very fancy lot. The price is 20c per lb. on board cars here. Who wants the lot? Address L. W. BALDWIN & SON, Independence, Mo. 19tfdb

WANTED.—One or two thousands pounds of nice comb honey. Write, giving amount on hand and price wanted. A. D. ELLINGWOOD, Berlin Falls, N. H. 17tfdb

WANTED.—White comb and extracted honey; state price, package, etc. B. WALKER. 17tfdb
Capac, Mich., or Prairie du Chien, Wis.

FOR SALE.—50,000 lbs. of extra fine sage honey in 60 lb. tin cans. Also two carloads of light amber honey, for sale at 6c per lb., f. o. b.

Black and Hybrid Queens For Sale.

I have 30 nice hybrid and 35 young black queens for sale. Send me 50c and get one of them.

16-17-18d A. D. ELLINGWOOD, Berlin Falls, N. Y.

Six hybrid queens at 25 cts each; these queens are young and extra prolific; three of them produce bees that show about all the markings of pure Italians.

L B SMITH,
Cross Timbers, Johnson Co., Texas.

CONVENTION NOTICES.

The next convention of the York and Cumberland Bee-keepers' Association will be held at Goodwins Mills, Me., Oct. 18, 1890. All persons interested are invited.

Waterboro', Me., Sept. 20, 1890. C. W. COSTELLO, Sec'y.

The 23d semi-annual session of the Central Michigan Beekeepers' Association will meet in Pioneer's Room, Capitol, Lansing, Mich., on Wednesday, Oct. 15. Everybody interested, come. Ladies are cordially invited to attend.

Grand Ledge, Mich. W. A. BARNES, Sec'y.

Vol. XVIII.

OCT. 1, 1890.

No. 19.

TERMS: \$1.00 PER ANNUM IN ADVANCE; 2 Copies for \$1.90; 3 for \$2.75; 5 for \$4.00; 10 or more, 75 cts. each. Single number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY

A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canadas. To all other countries of the Universal Postal Union, 18 cts. per year extra. To all countries NOT of the U. P. U., 42 cts. per year extra.

SOME QUESTIONS IN REGARD TO CYPRIANS AND SYRIANS.

DOOLITTLE'S EXPERIENCE IN REGARD TO A CLEANSING FLIGHT IN THE WINTER TIME.

Several questions have been sent in for me to answer; and as the most of them are appropriate for this time of year, I will, with your permission, Mr. Editor, answer them through the columns of GLEANINGS, answering them by number.

1. "Can Cyprian and Syrian bees be distinguished, by their color or markings, from the Italian bee or from each other?"

Well, that depends whether the asker of the question is expert in detecting nice colorings; whether he is a close observer, and whether he has had large experience with the different races named. The claim was originally put forth, that the Cyprian bee had a shield between its wings, of the same color as the golden bands on the abdomen, and that, as no other bee had this shield, it was therefore easy to distinguish the Cyprian race from that of any other. However, it was soon found out that the best specimens of Italians showed this shield fully as plainly as do the Cyprians, so that claim went for naught. Candidly, I do not know that I could tell a beginner how he could tell these races of bees apart, were there nothing but the coloring of each to go by. The yellow on the Syrian is of a little darker or duller shade than that of the Italian, while the same color on the Cyprians is of a brighter orange than that of the Italian, and much more so than that of the Syrian. This I say of them in their purity—not when they are considerably mixed with "blood" from each other, as is quite apt to be the case. When thus mixed, the best authorities are so badly puzzled that it is no wonder the above question was asked by one not thoroughly posted.

2. "Do the Cyprians and Syrians rear more brood than the Italians?"

Yes, as a general rule they do. The Cyprians, in my opinion, would be an acquisition, were it not for their vindictiveness, which is so great that it can not be tolerated. They commence breeding more profusely, early, than any other bee with which I am acquainted, thus getting many bees on the stage of action just in the right time for the white-clover honey harvest; while when the harvest is well under way they rear no more brood, to become useless consumers, than do the Italians. I never parted with any thing in the bee line with more reluctance than I did with the Cyprian bee. The Syrians are very different in this locality, regarding brood-rearing, from either the Cyprians or the Italians. They do not begin rearing brood to much more than supply the waste of the hive till the honey harvest commences, when they go to brood-rearing on the most extensive scale, this brood consuming the larger part of the honey gathered by the few bees they have at the beginning of the harvest; while this brood, after it has hatched into bees, becomes a consumer of the little honey they did not consume while in the brood form. I had from two to six Syrian colonies of bees for four years, and each fall I had to give them nearly all of their winter stores in the shape of frames of sealed honey taken from my Italian colonies. During this time I succeeded in taking about 50 lbs. of inferior comb honey from them. Of all the bees I ever had in my apiary, the Syrians proved much the poorest. Some speak well of them, and I think that they might prove better than with me where the season is of long duration for honey.

3. "Some say that bees need a cleansing flight where wintered in the cellar; others say that such a flight is unnecessary. Which is right? I do not wish to carry mine from the cellar till time to set them out for good, unless it is actually necessary."

It used to be thought, by nearly all, that bees should be carried from the cellar on pleasant

days during the winter for a fly; but of late years most of our best apiarists believe this is of no special benefit. I used to carry mine out, up to about twelve years ago. At that time I commenced to experiment by so arranging in the fall that I could carry a part out without disturbing the rest; and when there came a warm day these were carried out, and the rest left undisturbed. The result proved that, on the whole, those not touched wintered a little better, if any thing, than did those taken out; consequently I have not carried a colony out of the cellar for a cleansing flight during the last ten years; only as two or three have been carried out and fed, as I feared they would starve before spring. Some say, "Leave them as long as they are quiet;" but my experience has been that there is nothing gained by carrying out the uneasy ones, should there be any such; for if they are going to die, carrying out for a flight does not seem to help them much if any.

4. "Would there be any injury to bees if placed in a cellar under a kitchen where there is lots of noise all winter?"

If the bees are so arranged that no jar comes to them, so far as my experience goes, noise does no harm. It is the jar that arouses bees in the winter, not noise without jarring. To illustrate: In sighting my rifle one pleasant winter day I fired it within eight feet of two or three hives of bees. Just before firing I listened at the entrance of these hives and heard the low hum of the bees which we always hear; but before I had fired ten shots these same bees were all in an uproar, many coming to the entrance. At the time I laid it to the noise; but thinking differently a few days afterward, I again fired the same number of shots 50 feet in front of the hives (the first having been fired in the rear), so that the noise might reach them at the entrance, and they were not disturbed in the least. I now fired at the same distance as at first, when they became agitated the same as before.

G. M. DOOLITTLE.

Borodino, N. Y., Sept. 16.

Friend D., we are exceedingly obliged to you for your answers on the above subjects. I believe we almost if not entirely agree with you in regard to Cyprians and Syrians.—In regard to the cleansing flight in winter time, I think the general decision is about as you give it. So many have testified to excellent wintering right under the kitchen, where there is lots of noise, we can not think the noise would be any objection, providing the hives rest on the ground, and the jar of the floor does not shake the hives.

CALIFORNIA.

THE NUISANCE OF ODD-SIZED FRAMES.

In my California letter on swarming I did not say any thing about the swarm that took an old oil-can for a home, nor the one that built in the hollow shell of an old pumpkin, nor yet of the one that came down the chimney into the fireplace below, to the astonishment of the family in the room. This last was down near the river, where there is more timber than here. Such are some of the wonders of California bees. They are put into all sorts of boxes for hives. Nail-kegs, barrels, and store-boxes I have seen used. Even where regular hives are made, they are made according to the size that the lumber will cut best for, more than to any regular or standard size. A dealer in supplies here showed

me his patterns for cutting foundation by; and how many do you think there were? About 30. I should say, though I did not count them. It is everywhere evident in California bee-keeping, that the bees are made to be secondary to other considerations. They are not valued here as they are in the East. The fixtures of an apiary, including hives, contain a larger per cent of the value of an apiary here than there. It is not so hard to increase here. Sulphuring, or killing bees, is often done to get the honey, where some one has taken a swarm or two in a box or keg some months before.

In the apiary we bought, we found about four sizes of frames for the same size of hive. The hives and frames were substantially made of good material, and would have been good property had the maker fortunately understood the proper size of a bee-space. I can say that I understood far better what the proper distance was before commencing with bees at all than the owner of this apiary did. I read the A B C book, and had the fundamental principles well fixed before commencing.

We found frames in our apiary that we could hardly push down between the waxy walls of the hive, and frames that stood away fully $\frac{3}{4}$ of an inch from the sides, and frames that did not come within more than an inch of the top of the ones below. The bees were obliged to build in between in order to crawl up on the upper frames, which made very bad work when removing a frame. I suppose Mr. Root wouldn't tolerate such frames for a day longer than absolutely necessary, and I am sure we will not, for they would drive us out of bee-keeping altogether. Buying and selling bees is much hindered here by the many sizes of hives used. The buying of bees usually means a transfer to your own size of frames, and there is not much selling in lots less than a whole apiary.

The average California bee-keeper is apt to "lump" things, as the expression is. If it is a good year he expects a good yield of honey; and if a poor one, he reasons that it doesn't make much difference. I can not say that the bee-men here are as progressive and intelligent as they might be. Among the large bee-keepers are men of fully equal capacity to those in other lines of business; but it seems to be resorted to sometimes as a make-shift way of getting a living. Perhaps I am wrong about this, and the neglected appearance of many California apiaries may be due to the fact that persons of small means take this way to procure a living, and stretch their capital to accomplish as much practical result as possible, so that the appearance is much neglected. Afterward these persons embark in other enterprises, and leave the apiaries in the hands of others just commencing business, so that no outlay is made in the way of taste and appearance. If the outward appearance of many apiaries and their surroundings were any index to the quality of the honey produced, I should not wonder that it brings a low price in the world's markets. Some one who could get up extracted honey as nicely as Mr. Terry does his strawberries would doubtless find it to pay. It is possible to cleanse oil-cans so that they are clean, and free from taint; yet carelessness in their use has doubtless done much to lower the quality of the California product.

BEES AND FRUIT IN CALIFORNIA.

"Bees versus fruit" is a question I suppose you who are old bee-keepers have discussed until you hardly care to say any thing more about it. But it is all new to me; and when I saw the fruit of my neighbors covered with my bees I suppose I felt that there were at least two sides to the question. It is claimed by some here, that the bees eat into sound fruit to obtain the

juice. Others say that they take only injured fruit that birds have first worked on. I have taken neither view, but so far have only seen the little fellows run over the fruit, lapping with the wonderful appendage they have for taking honey, and not using the parts with which they uncap comb honey. I can see, however, that, by constantly taking away the juices, the dry substance of the fruit would soon shrink very much when unprotected by the film of dry juice that would otherwise form a covering over the injured part. In this way fruit melts away where there are many bees to keep the juices cleaned off, and the owner may reasonably attribute a loss to the agency of bees. My neighbors have been lenient in these matters, and refused to accept any thing for their losses. Yesterday, while picking figs I came to a white fig-tree that had a sound as of a swarm, because of the many bees that were working on the fruit. Grapes are worked on by them until only the shell or skin is left; but, as in the case of the figs, it is fruit that has begun to candy in the juices, and is not ripening perfectly. A mean between the entire prohibition of bees in fruit-districts and the putting of large apiaries in positions close to fruit-farms, especially where other locations will answer as well, would seem to be the right solution of this question. Where one man owns both bees and fruit there will never be any trouble, and there should not be in any case.

I was rather surprised to find honey in the hives, almost ready for another extracting. The bloom of most of the flowers is gone, and I did not suppose the bees were getting enough from the fruit to accumulate much stores. But I noticed that the bees working on fruit would get either such a large load, or the effects of the juices were such that they were hardly able to take wing, and seemed half drunken. I have caught the great steel-blue wasp, with scarlet wings, when it was working on fruit, as it seemed to lose fear. This wasp is over 2 inches long, and is very beautiful. There is alfalfa down in the valley, about three or four miles away, and I have hoped that our bees would find it, as it would help much in the present dearth of bloom on the high land. I am sending my honey home to my brother in Ohio; and there is satisfaction in thinking of my old neighbors and friends getting my honey to use. God bless them all, and draw them near to him with the bands of love.

The yield this year has not been as great as we at one time expected. We shall get about 40 or 45 cans in all, which is not a large yield from 70 hives. The white sage put forth multitudes of buds which did not mature into bloom. Had they done so, four apiaries like ours would not have kept them emptied of an ordinary honey deposit. But they failed, for lack of moisture, perhaps, and we are content with less than might have been. There has been fruit to work with and engage our time. God has been merciful, and we do not have a right to complain at all.

COMBS MELTING DOWN WITH HEAT.

We shaded our hives, as it is necessary to do here, and ours were in a low place where the sun struck strongly. An oil-box costing five cents made two shades. One very hot day while we were away in Los Angeles a hive melted down into a mass almost. It seemed to be because of a large stone that stood on the north side, and reflected the rays into the hive. The same day a man in the village who had but one hive (or box, rather), in which the bees built to the top inside, had it melt down by the heat of the sun.

Comb honey at 12½ cents, or nicely extracted honey sent to some friend in the East to sell,

will pay pretty well, I think, here in California, where so little capital is needed for an outfit. Retailers here charge well for handling any thing in the food line, though I can see that their margin is being lowered all the time. A year ago, grocers at Los Angeles sold honey, that cost them 12½ cents, at 20 cents. This year it is 15 cents at retail, as the style is to go 5 cents at a time, which is a relic of early days, when nothing less than 25 cents was accepted for *any* thing. Where one can dispose of his product direct to the consumer there is a good profit; but you can not well do this if you go back in the new districts away from the cities, where the best bee pasture is. But if near a small village or town, there may be a pretty smart local demand, as the majority of the people will be engaged in other lines of business, and may be willing to give you a better price right at home than you could obtain by sending to the large markets.

FLUCTUATION OF PRICES IN CALIFORNIA.

Prices fluctuate wonderfully here, especially on heavy articles like potatoes, which range from nothing up to 3 cents a pound. Every thing of food is sold by the pound, with the single exception, I think, of comb honey. Business does not move as steadily and systematically here as in the older East. There are more ups and downs. True courage and moral worth are recognized here as quickly as anywhere in the country. A man's clothes or his pedigree counts but little. They make a quick estimate of a man of what there is in him; and if he has good elements of character, and wants to do what is right, they seem quick to understand it, and reward it accordingly.

W. S. RITCHIE.
Sierra Madre, Cal., Sept. 8, 1890.

Friend R., I remember vividly almost every point you make; and I thank you for your candid and honest statement in regard to the matter of bees and fruit. I noticed your concluding thought, that people in California make a quick estimate as to a man's real value. Fine clothes and plenty of money do not of themselves give him a place in society where other things are lacking. I expect to see California lead us in many things; and I hope and pray that it may be in placing a high estimate on the value of true Christianity.

THE FOUR CLASSES OF BEE-KEEPERS.

A PROPOSED 8-FRAME CHAFF HIVE: 8 VS. 10 FRAME L. HIVES, AGAIN.

Mr. Root:—Now that your great rush of business is over, and you have had a little time to rest and cultivate charity toward those that want "irregular supplies," I wish to make a suggestion of two, which I hope will result in adding a new (?) hive to the regular list.

First, let me say, in commendation of the chaff and Dovetailed hives, that, for the class of bee-keepers for which they are fitted they are the nearest perfect of any thing on the market. If we classify bee-keepers according to their method of wintering, considered in connection with the kind of honey produced, whether comb or extracted, we shall have the four classes suggested by the following headings:

1. Indoor wintering, comb honey.
2. Indoor wintering, extracted honey.
3. Outdoor wintering, extracted honey.
4. Outdoor wintering, comb honey.

The verdict of the leading honey-producers seems to be, that, for the production of comb

honey, the brood-nest should contain eight S. frames; and for extracted honey, ten. I believe this verdict is concurred with at the Home of the Honey-bees.

Upon the subject of outdoor wintering, there may be some diversity of opinion as to the superiority of the chaff hive; but there has been no uncertain sound in regard to the matter in the editorial teaching of GLEANINGS, as we have been repeatedly advised not to winter bees out of doors in Simplicities, but to lift frames and all into chaff hives.

Little has been said in regard to the wintering qualities of the Dovetailed hive, even by Ernest, who has been so enthusiastic over it in other respects. The senior editor has stated quite unreservedly, that he regards them inferior to Simplicities as a protection against cold, wind, and rain.

Now, the requirements are met for those that produce comb honey and winter indoors, by the eight-frame Dovetailed hive; for those that produce extracted honey, and winter indoors, by the ten-frame Dovetailed hive, and for those that extract and winter out of doors, by either the one or two story chaff hive; but according to your own teachings you make no hive that is adapted both to the production of comb honey and for outdoor wintering. I think I am safe in estimating that four-fifths of the ten thousand bee-keepers that subscribe for GLEANINGS belong to this unprovided-for class, and that they keep a larger number of colonies of bees, and produce more tons of honey, than any of the other classes—I was about to say, more than *all* the other classes.

If one of this class were to send you an order for hives suited to his needs, he would be charged extra for being "irregular;" and if during the busy season, he would be unable to get them at all.

All the preceding remarks have been only preliminary to the following suggestion: That the committee which designed the Dovetailed hive be re-assembled, and requested to give us an eight-frame one-story chaff hive that will take the eight-frame Dovetailed furniture above.

If this suggestion meets with favor, I should like to say something additional to the committee before this new(?) hive takes its final shape.

W. A. KING.

Marysville, O., Aug. 16.

Your classification of bee-keepers is very good; and while we have not yet hit the fourth class, as you suggest, directly, we have had it in mind; and the "committee," as you are pleased to call it, has been talking and arguing on an eight-frame chaff hive—that is, something that will be cheaper than our regular ten-frame, and yet answer the purpose fully as well. We have been experimenting along this line, but as yet have not said anything in print, because it is better to test new things at the Home of the Honey-bees than to have beginners all over the land try something that we *think* may be all right, and yet which may ultimately prove after all a failure to them. Well, perhaps it will do no harm to tell what the eight-frame chaff hive is that we have in mind. Hundreds of bee-keepers have the eight-frame Dovetailed hive, and they may take a notion to winter outdoors either a half or all of their colonies, because the cellar, if they have one, is too damp, or because some other condition is not right. They have

the hives on hand, and desire to winter outdoors. Now, how shall we fix them up? If it is practicable, and subsequent experiments justify it, we propose putting on the market a winter case made of $\frac{3}{4}$ lumber, dovetailed at the corners. This case will be $\frac{3}{4}$ inches deeper and larger all round than the eight-frame Dovetailed hive, and it is to have a tin-roof cover. By dovetailing the corners we find we can make it of much lighter lumber, and we are also able at the same time to dispense with corner-posts. Well, this winter case, or cap, is to be set directly over the regular eight-frame Dovetailed hive, and is deep enough so that the edges can be pushed down into the sand or sawdust around the hive. We then virtually have a double-walled hive, with a dead-air space, so called. This air-space will be sufficient for moderate climates; but for colder regions, possibly even for the locality of the Home of the Honey-bees, we shall be obliged to use additional packing. To accomplish this, we make a cushion in the form of a ring, just large enough to put around the eight-frame Dovetailed hive, and another cushion on the cover. The case would be then just large enough to slip over the whole snugly, and crowd down into the sand or sawdust, as before mentioned. The expense of the case, when put on the market in lots of 100, would be about 35 cents each in the flat. As the chaff, or some absorbent, can be obtained cheaply in most localities, each bee-keeper can make for himself the cushions he would need. Now, please bear in mind that we have tested a similar arrangement only one season, and on a rather limited scale. While it was successful last winter, the weather was too warm to prove any thing. This will make the cheapest double-walled arrangement ever before offered in the market; and if successful, I do not see any reason why it should not supersede all other more expensive double-walled hives, because it can be so readily adapted to eight-frame hives already in use, that have no projecting porticoes.

You say, friend K., that even GLEANINGS will admit that a ten-frame hive is better for extracted honey. While we did so, the junior editor wishes to argue now for eight-frame hives exclusively, both for comb and for extracted honey. Perforated zinc, when placed over a brood-nest of eight frames, *promises* to work a revolution. Read what L. E. Mercer said on page 674, last issue, in regard to the proper size of a brood-nest in connection with perforated zinc. If we can force a queen to fill eight frames of brood below, by the use of the zinc, let us have the use of the upper story for extracting combs. Mr. Mercer says, and our own experience, and the experience as well of thousands of bee-keepers, goes to show that, as soon as the queen has filled seven or eight frames, she will, unless restrained, go above and lay. I believe that intelligent bee-keeping of the future, with eight frames, Langstroth size, will

rear all the bees that will be necessary for a good rousing colony, provided that those bees are reared *in time* for the honey harvest. This is a fruitful theme, and we trust that our subscribers will thoroughly discuss it. Let some of those California bee-kings—that is, those extensive extracted-honey men—give us some hints.

ERNEST.

In addition to what Ernest has said above, I wish to touch upon another point. I do not believe that any hive will ever become popular that is made with the intention of removing the packing or winter covering in summer time. After you have once protected a hive suitably for wintering, do not think of removing the protection in the summer time. The bother, complication, loose pieces, litter, etc., is too much, especially where hives are handled by the hundreds or thousands. Sooner or later, putting on packing will be neglected, and a great many times it will be off at the very time it is needed. Ernest's talk about 35 cts. reminds me somewhat of my visions of cheap things years ago. Make your protection in the shape of something good and substantial. Have it painted, and nice; and if you do this, it will come pretty near a chaff hive made a little smaller, with the view of having only 8 instead of 10 combs in the brood-nest. Many thanks, friend K., in regard to the "committee." Where so much is at stake, it needs a *committee* of the best bee-men the world affords. Where hives or fixtures are made by machinery, in carload lots, they ought to be made *right* if it is a possible thing to have them so.

AN ARTESIAN WELL IN SOUTH DAKOTA.

ARTESIAN WELLS IN GENERAL.

Our readers need hardly be told that every thing in the line of springs, underground water-courses, and especially artesian wells, have a special attraction for me. A few days ago, when one of our correspondents sent me a photograph containing the view above, I almost felt as if I *must* take a trip to Dakota to see it; and I would very freely give the amount of money needed if I could be spared at this time to see this wonder of nature.

Below is what our friend tells us about it:

I send you a photograph of one of our artesi-
ans, thinking you would like to see it; and if
you would like, I will send you some of the
specimens which it throws out. It will throw
a 6-inch stream 24 ft. in the air, and a 4-inch 71
ft. The 4 is the one they use for fire. It will
throw a 4-inch stream 100 feet without spray-
ing.

J. W. CHAPIN.

Winfred, Lake Co., S. Dak., Sept. 1.

In addition to the above, we find printed on the back of the photograph the following:

Depth of well, 725 feet; diameter of bore, 6 inches; conservative estimate of pressure, 175 to 200 lbs. per square inch, and discharging every minute over 4000

gallons of water. It is conceded to be the artesian wonder of the world.

By looking closely you will see a pool of water that has collected round about the well. Judging from the buildings, we suppose the smaller jet was screwed on when the picture was taken. By all means, friend C., send us some of those specimens. We have a curiosity to know what is down in the ground where these subterranean waters come from. Four thousand gallons of water would be a hundred barrels of about the size of an oil-barrel, every minute. Just think of it! This water, if all utilized, should irrigate almost a whole county. Friend C., will you

WOONSOCKET'S FAMOUS ARTESIAN WELL.

please tell us how deep they had to drill for it? and have there not been other wells drilled in that vicinity, to see if the same subterranean supply may not be touched from other localities? Is it really the largest artesian well in the world? Perhaps the readers of GLEANINGS can kindly enlighten us. One reason why I ask is because such wells are really of more value than gold-mines, providing the flow is permanent, and I believe it usually is. You see, I have a little one of my own. It runs only 50 barrels a day, and it won't carry the water over 18 inches high; but still I feel very happy over it for all that. It is away down in the creek bottom, where it is difficult to utilize it; but if the water would rise only three feet instead of half that much, I could send a part of it up to the factory by a hydraulic ram. The springs scattered all over our land should be utilized. Spring water is too valuable to be allowed to go to waste.

SOME EXTRACTS FROM FOWLER & WELLS' WATER-CURE MANUAL.

THE GREAT "SECRET," OR "DISCOVERY," COPY-RIGHTED IN 1847, AND PRINTED IN 1850.

I wish all readers of *GLEANINGS* and the *Microcosm* would put your articles on the subject, and this reply of Dr. Hall's, side by side, and then decide which shows the spirit of an honest, Christian gentleman.

My sympathies are with you, because I believe the principle on which you acted in this matter is right, and that your motive was purely unselfish; so I take great pleasure in sending you some extracts copied verbatim from an old *water-cure manual*. The book referred to is "The Water-cure Manual," by Joel Shew, M. D., copyrighted in 1847, printed by *Fowler & Wells* in 1850. Speaking of these injections Dr. Shew writes:

"They may be repeated again and again, in as great quantity as is desired. . . . A good mode, too, is to take a small injection, a tumblerful, more or less, that is retained permanently, without a movement before morning. This is very soothing to the nervous system; aids in securing sound sleep, and, by its absorption in the coats of the bowels, dilutes acrid matters therein, tonifying and strengthening likewise those parts, and aiding materially in bringing about natural movements."

After naming various diseases for which this remedy is invaluable, he says:

"This statement will cause sneering, I know; but it is no fancy sketch. The thorough washing out, so to say, of the lower bowels, by which the peristaltic, or downward, action of the whole alimentary canal, is promoted, and by the absorption or transudation of water its contents are moistened and diluted, and the whole of the abdominal circulation completely suffused by that blandest and most soothing of all fluids, pure water. Whoever understands well the sympathies and tendencies of these parts of the human system will at once perceive the truth of what I affirm."

Let me add: Whoever reads this can at once perceive the truth of what you affirm; viz., that Dr. Hall has simply revised one of the old methods of water cure, and has no business to call it a "secret" or "discovery," or to sell it as such.

E. J. BAIRD.

Island, Pa., Sept. 11.

Many thanks, my good friend B. Since you mention it, I remember now that water cure was one of my hobbies when I was only eleven years old. Soon after, I bought the book you mention, of Fowler & Wells; and when I first saw Dr. Hall's discovery there was something strangely familiar to me about it; but as it was toward forty years ago, it is not much wonder that I had forgotten where I obtained my information. When about ten years of age I was a very weak, puny, feeble child; and a traveling lecturer on phrenology and water cure gave me my first ideas, and started me in daily bathing. I distinctly remember this: That in two or three months I astonished the whole family by taking a pail of water from outdoors, breaking the ice, then washing all over in the ice water, without feeling any more unpleasant than you do, my friends, when you wash your face in ice-cold water. After my bath, the new doctor prescribed walking a mile before breakfast. Luckily we had a cow pasture just half a mile

away, and that fixed it just right. I was appointed to fill the post of driving the cow home before breakfast. I hardly need tell you that, under the influence of the daily baths and morning walk, I soon developed a degree of health and vigor that I had never known before in my life. I think I read the book through several times; but, of course, I did not pay very much attention then to the matter of water cure by injections.

MAMMOTH PEAVINE CLOVER.

ALL OTHER SOURCES OF NECTAR PRACTICALLY A FAILURE DURING THE PAST SEASON.

The honey harvest is over. My crop is gathered and marketed. I have sold my comb honey at 16cts. and my extracted at 13. Nearly all my comb honey, 2000 lbs., was obtained from my Bronson apiary, numbering 60 colonies. That apiary is located where the bees have access to probably between 300 and 400 acres of mammoth clover, and the honey was nearly all obtained from that source. Every year furnishes me with additional proof that the mammoth, or peavine clover, is the best honey-plant we have on the Western Reserve. My home apiary, which is located about 5 miles north of my Bronson apiary, did not average 5 lbs. to the colony—only $\frac{1}{2}$ as much as the Bronson apiary.

I wish to call your attention to an invention of my friend H. R. Boardman, which I think is of more value to the bee-keeper than any other invention pertaining to our business which I have seen or heard of in a long time; and that is, a solar wax-extractor. I purchased one of him about six weeks ago, and it does the work perfectly for which it was intended. The wax is extracted from old combs readily, and without any waste whatever, with less trouble than it would be possible to extract it any other way.

BOARDMAN'S SOLAR WAX-EXTRACTOR, AND ITS EFFICIENCY.

I think any man who has 50 lbs. of wax to extract, a year, would save the price of the extractor in two or three years by using one. I think you will do the bee-keepers of this country a great favor if you will get of friend Boardman a complete description of his extractor, and publish it in *GLEANINGS*. I don't know whether he intended to have his invention patented or not, but I think not.

My whole crop of honey, both comb and extracted, will amount to over 4000 lbs.—not a very heavy crop, but pretty fair for this year. If I had not sold, I could now sell my comb honey at 18 cts.

S. F. NEWMAN.

Norwalk, O., Sept. 19, 1890.

Friend N., you have given us just the kind of report in regard to the peavine clover we have wanted. Now, then, it is pretty certain that bee-keeping can be made to pay wherever this clover can be introduced by the hundred acres; and that is the way to raise any honey-plant so as to make it really practicable. Another thing, the quality of the honey will be equal to any in the world. All that is necessary is to introduce it and furnish a sufficient inducement to the farmers round about you to grow it largely. Terry's teachings will probably dovetail in, to the mutual advantage of both the bee-keeper and farmer; and, to sum it up, we may say clover is the rock-bottom of success, whether

you wish to raise honey, potatoes, or strawberries. I am really glad to have you give friend Boardman such a recommendation. Now, friend B., tell us all about this wonderful invention, and whether you have them to sell, and at what price. It can not be that they cost very much, if it will pay a man to have one who produces only 50 lbs. of wax a year.

ERNEST'S NOTES OF TRAVEL AMONG THE BEE-KEEPERS OF YORK STATE.

AT JULIUS HOFFMAN'S: THE HOFFMAN FRAME, ETC.

After bidding good-by to our friends the Van Deusens, we started on our journey again, Mr. Elwood driving, and I hanging on to the bicycle at the back of the seat. Whenever we struck a rut or hole in the road, it gave my arm a good jerk. It may have seemed somewhat of an anomaly to passers-by for a bicycle rider and his wheel both to be carried in a wagon. It was not because the wheel would not carry me, nor because the country was hilly and rough, but that we might have an opportunity of visiting together as before mentioned. I am afraid if it had been possible to carry my friend Elwood on the rear of my vehicle, folks along the road would have stared even more than they did, for our Starkville friend weighs more than 200 pounds.

As we went over the roads, I noticed in this hilly country that the effort of late years had been to *avoid* hills rather than to go straight *over* them. Although somewhat paradoxical, many times, the longest way to a point among these hills is the shortest. The early settlers formerly made their roads go in a bee-line over the hills, or very nearly so. The result was, there were some terrible climbs for poor horses. But later generations discovered that they could make better time by going further and *around* the hills.

As Mr. Elwood was to take a somewhat different route than the one he had before taken, he had to make inquiries along the way. The point we wanted to reach was the home of Julius Hoffman, two or three miles out of Canajoharie. We noticed on this journey what I had before and have subsequently observed, that residents along the roadway very often have very crude ideas as to distances. For instance, we would inquire of some old rustic how far it was to the next town. The reply would be (we'll say), "Five miles." After having traveled half an hour, on the right road, perhaps our next informant would say that it was six miles. It was perfectly evident that one or both (probably the first) must have been wrong.

After driving along in this sort of way we finally came to within a respectable distance of Canajoharie, which used to be the old home of the *Bee-keepers' Exchange*, a monthly bee-journal edited and published by J. H. Nellis, later by Houk & Peet. It was discontinued in 1883. If I remember correctly, Mr. Nellis is still located in Canajoharie, though not now a bee-keeper. If we had had a little more time I should have liked very much to call on him and exchange greetings, in view of his past services as a bee-keeper and a bee-keeping editor. I have a kindly sympathy for all this latter class of people, especially as we know somewhat of the trials of publishing a bee-journal.

We did not go to Canajoharie direct, but made a short cut directly to Mr. Hoffman's home. Mr. H. formerly lived at Fort Plain; but lately he has been located as above. On

arriving at the place we found a very pretty residence, and a general appearance of thrift. Not knowing exactly the date when I should be at Mr. Hoffman's, and not having written him, I was a little uncertain whether I should be able to find that gentleman at home; but fortunately we found him there. He is not as old a man as I expected to see. We found him to be an intelligent and progressive bee-keeper, an energetic representative of his "fatherland," Germany. After dinner we went out into the home yard. I told Mr. Hoffman that I was anxious to see him handle those frames.

THE HOFFMAN FRAME.

He handles his frames—the Hoffman, before described in these columns—with rapidity and ease. While he did not remove and replace them any more rapidly than Mr. Elwood did his closed ends, I am sure he manipulated them in less time than most of us would the hanging frame. In former years he tried the hanging frames thoroughly; but as he could not handle them rapidly enough, and they were never ready for moving, he adopted the Berlepsch top-bar, something after this pattern, and subsequently,

if I remember, widened the end-bars near the top, making what is generally known through this section of the country as the Hoffman frame. Here was a bee-keeper who had 500 or 600 colonies, and I think he uses only one assistant, and him only part of the time. He attributes the reason why he can run so many colonies in several different out-apiaries, practically alone, to the fact of his using fixed distantes. He would open up a hive, unloose the follower, and then he would pick up five or six frames at a time, put them down by the side of the hive, and perhaps the next frame we picked up would have the queen. Then when he got ready to close the hive he would pick up all the frames that were leaning against the hive, and insert them back in their place simultaneously. With his two thumbs on the outside top-bar he would crowd all the rest of the frames together.

One of the reasons why Mr. Elwood and Mr. Hoffman, and all the rest who use fixed frames, economize in time over those who use hanging frames, is in the final spacing. It is true, both use a knife or a screwdriver to start the frames; but I noticed that Mr. Doolittle with his hanging frames also uses one; in fact, so do all who use hanging frames on wood rabbets. As to the propolis sticking the closed ends together, so as to make the manipulation difficult, that is more in theory than in practice. Like Mr. Elwood, Mr. Hoffman could get his colonies ready to move on short notice. He had an ingenious wire-cloth button, so arranged that, by turning it, it closed the entrance with wire cloth, and, in less time than it takes to tell it, he could fix up any of his colonies ready to move to an out-apiary.

Mr. Hoffman runs for extracted honey only; and as he has produced tons of that article, I took occasion to ask him about extractors. He had been using a Stanley automatic reversing machine. While not altogether pleased with it, he thought there were a number of good features about it. He prefers something of his own design. This, if my memory serves me rightly, is a four-frame non-reversing extractor. I think he has used a Novice machine, but considered its capacity too small for his work.

After we had looked around awhile through the honey-house and the apiary we went into the house. Mr. Hoffman is an intel-

ligent, progressive German. It was very evident that he is well versed in all German bee-literature. He spoke of Berlepsch and one or two others who advocated 1 $\frac{3}{4}$ -inch spacing. As he could not then refer to the authority at the time of my visit, at my request he prepared the article that appeared on page 673 of our previous issue. As usual, I explained that my time was limited and we should have to be moving. After hitching up we bade our friend good-by and started on the road again.

SHARON SPRINGS.

The next point we reached was quite a celebrated pleasure-resort, as above. Many were there, both for pleasure and for health. I do not know that I should object very much to spending a few days here myself. Our time was rather limited; and after driving hurriedly about, Mr. Elwood stopped in the rear of a large hotel, and asked if I should like to step around in front of the structure. I did so, and, presto! one of the most magnificent views of the Mohawk Valley was spread out before me. Miles and miles of territory were to be seen off in the distance. Gently curving this way and that was the Mohawk River. On the right and left, as far as the eye could reach, were those beautiful hills. Distance lends enchantment to hills to a bicyclist. I wish I had the language to express the emotions that came to me then. I am not at all poetic; but our stenographer comes to my aid by quoting the words of the old song:

Sweet is the vale where the Mohawk gently glides
On its clear winding way to the sea.

I am very sorry indeed that I could not have uttered that on the spot; but, as Mark Twain says, we do our thinking after we get home. After feasting my eyes, I went hurriedly back to where my friend was holding the horses. I suppose he thought I was in an "awful sweat" to get off on the wheel again; but the fact was, Mrs. Root was expecting me next day; and I knew that, if I did not arrive at Durham on the mountains, where she was visiting with friends, at just the appointed hour, she, like a good many other mortals of her kind, would worry. Much as Mr. Elwood had carted me about, he insisted on carrying me over the first big hill. As I came to bid him good-by, it was with some feeling of sorrow. Our Starkville friend is a man with whom I feel it an honor to be acquainted. He is not only an extensive bee-man, but he is progressive, and thoroughly alive to all that may benefit his brother-man, whether he be a bee-keeper or not. He is modest and somewhat reserved, and at first not very communicative, but has a loving heart when you come to know him. Before and after my very pleasant visit I found all along my journey that bee-keepers generally hold him in very high esteem, and I do not much wonder at it. It was not my pleasure to meet Capt. Hetherington, one of his most intimate friends; but I covet the pleasure of seeing him some time.

A FEW STRAY BITS.

Just at this point I recall that my mother and my better half remind me that I have made no mention so far of bee-keepers' wives. Just you wait, dear readers. There are so many things that I want to say that it is hard to crowd 'em all in at once.

Another thing that I am reminded of, is, that these stray rambling thoughts may subject the bee-friends whom I visited, to an unusual amount of correspondence. If I have not been explicit in details I would beg our subscribers to write to this office, rather than to the gentlemen I have mentioned. Most of them are ex-

tensive bee-keepers, and their time is quite fully occupied; and when we do get any correspondence at all from them, it ought to go, not to one individual, but to thousands of readers.

I am reminded, also, that, from what I have said about this section of York State, a few perhaps prospective bee-keepers will consider the propriety of moving into these localities. Allow me to say that they are pretty well occupied by bees already; and if any one thinks seriously of locating among these hills, he will have to buy out some bee-keepers already in possession of the territory, if he wishes to be honorable about it. Elwood has 1300 colonies; Capt. Hetherington 3000, probably more; Mr. Tunnicliff, Mr. Smith, and one or two others, have perhaps among them another thousand colonies. I noticed that these out-apiaries were just as thickly crowded in as they could be and not overlap each other's territory. While I am quite firmly convinced that this is one of the finest bee-countries in the world, I do not wish to have the friends who so kindly entertained me have some one else come in with more bees, and overstock the fields. Come to think of it, I am sure no one will; therefore, please excuse me.

These thoughts may seem a little out of place to interject right at this juncture; but if I do not give them here, I am afraid I shall forget to do so.

Well, here we are

ON THE BICYCLE AGAIN.

As we spent a little time in sight-seeing, it was about 5 o'clock when I left Mr. Elwood. I then had about twelve or fifteen miles to make. At nightfall I arrived at ——. I could have gone further to the next town; but as this section of the country was, of course, entirely new to me I did not particularly relish traveling among the hills, unaccompanied, unarmed, and alone. I realized that I had made somewhat faster time on the bicycle than we had when driving. As the place was small it was not difficult to find a hotel, which, having entered, I called for supper and lodging. My heart sank within me, for I saw that it was one of those places where a bar was evidently doing a thriving business. There were bottles and glasses; and while I did not feel at all inclined to patronize it, I felt very much disinclined to patronize the proprietor, even for such innocent things as supper and lodging. However, my bicycle was leaned against one side of the room; and after washing I partook of a hearty supper. On returning to the room again I discovered that a number had come in to see "that new arrival" and the wheel. They were mostly local sports, and men whom I judged patronized the bar. They were not altogether choice in their language, and the company was decidedly rough. I very much wished then that I had taken my chances of riding in the dark to the next stopping-place; but there was no help for it then. I would have gone to my room, but I did not exactly like to leave the bicycle to the tender mercies of those chaps. Ere long more came in, and then the drinking began. I fancied they eyed me rather suspiciously. Visions of robbery flitted past my eyes; and then I reflected how foolish I was. I carried but little ready cash, a small check, and a Waterbury watch. They wouldn't touch me, especially if I displayed the aforesaid timepiece. Before I retired, swearing, disputing, and drinking had been carried on to such an extent that I actually feared there would be a fight; in fact, it started, but the proprietor mollified the would-be fighters. I vowed then that I would never stop again in such a place, even if I had to travel all night, unaccompanied, unarmed, and alone, over an

unfamiliar and unknown road. At about ten o'clock the company dispersed, and I went to my room, somewhat disgusted and pained. I did not reprove the fellows for their bad language. Indeed, they were a class of toughs, I might say, whom I did not wish to argue with. It was my misfortune to stop at two or three such hotels; but only in the above case did I remain over night. It was very evident that the presence of liquors cursed the whole establishment. There was always a set of hard-looking customers—men whom I would hardly dare to trust out of my sight. On the whole, however, these wayside hotels were no worse than the average of those in Ohio, if I except the two or three I have mentioned.

Next morning I arose early, refreshed; and after an early breakfast I took a start on the bicycle, about seven o'clock, for Durham, on the Catskill Mountains. I had been informed that there were two or three quite prominent bee-keepers on the route. There were fifty miles ahead of me, over some hills quite as high as those I had gone over, besides the two or three bee-keepers whom I wished to visit. Should I be able to make it all in one day? We'll see. My first point was Cobleskill, a run of about fifteen miles, which I reached in about an hour and a half. It is a very pretty place through which passes a mountain railway, and here I had the pleasure of making the acquaintance of Mr. B. Van Wie. He keeps about 100 colonies. The bees had done nothing for him this season of any account, although they were, at the time of my visit, working pretty well on buckwheat, and he will probably get a pretty fair crop from that source. I was very much annoyed on my bicycle routes by poor and insufficient directions as to the best route to reach a given point. I told Mr. Van Wie that I should have to make my stop necessarily short, as I had a good many miles ahead of me, and wished to reach Durham that day. He very kindly gave me most complete directions. The result of it was, I was enabled to accomplish my journey of 45 miles easily in about six hours, and visited the before-mentioned bee-keepers that day, for which Mr. V. has my thanks. After eating two or three Red Astrakhan apples (oh how good they tasted after my bicycle ride!) and taking a refreshing drink, I took myself to the wheel again.

[To be continued.]

GETTING BEES OUT OF SECTIONS OR EXTRACTING-CASES.

BEE-ESCAPES A GREAT BOON TO THE BEE-KEEPER.

On page 555, Aug. 1, Mr. Doolittle writes about getting the bees out of the sections and the extracting supers, and asks for an escape that can be put on at night, and take the sections off in the morning. Perhaps to help him and others, a little experience of my own and of others that I know may help some. The main trouble with all escapes, so far as I know, is the lack of depth of the case to which the escape is attached; and, like some other things, accidental occurrences have given the clew. Without trying to take any laurels from any one, I will tell of the first escape that I ever saw, which was some years ago—I can not tell how many; but it was taken from the old-fashioned cottage fly-trap, and was made from two of the inside pieces. They are $5\frac{1}{2}$ inches wide by 6 long, bound all round with tin, and bent at right angles. They have eight holes, $\frac{3}{4}$ inch in diameter, made where the wire cloth is bent. Two of these were put into a box with sides and ends

about 3 inches deep, which brought the ridge of the wire cloth within about half an inch of the combs in the hive, so that, after a time, the bees would begin to work back into the boxes again. This fixture was used on the old No. 2 American hive, under the old style of King sections; but it worked well unless it was when the colony was very strong, and the last row of sections was to come off; then there was trouble about getting all the bees off from the combs, and many of them would be defaced. Then when Mr. Reese put out his escape, in 1887 (which, I believe, was the first time the subject came out in print), he advocated the double cone, which is a very necessary feature in the successful working of the escape. I knew of perhaps 100 of those escapes being made to be used in 1888, with a varying depth of case from 3 inches up to 8 inches, and with from 2 to 8 cones, with both single and double cones, and this is how they succeeded. In the shallow ones there was a half-inch board used for the base, or dividing board, with a $\frac{3}{4}$ space above, and the cones were about 2 inches deep, some single and some double, because some of the makers and users knew that one cone was just as good as two. Some of them, the cones were nailed on the under side of the board, and some were nailed on the upper side, and projected through a hole bored for them. Deeper ones were made in like manner, and usually were made from just such pieces of boards as were handy. I made 25 or more myself; and to try them I used various depths from three to six inches, but they mostly were of 4-inch depth. Those that were shallow did not empty the sections as quickly or as clean as the deep ones, and quite often the bees would learn the way up and down when they were left on for two or three days, and the swarm was very strong; but in a trial with three escapes 6 inches deep, and two that were 5 inches deep, that were left on the hive for over a week, not a bee was found in the sections after from two to five hours, which showed that depth gave success.

Now, the way that I found the depth being the clew, is this: I was telling a friend about them, early in 1888. He picked up a board 8 inches wide, and from a strip of wire cloth from seven to eight inches wide we made ten cones by cutting it square and putting five cones on each side of a half-inch board, with three-inch holes. This let the cones have a good half-inch space between, except at the outlet. I saw him again in July, and learned that he could clean a case of sections in half an hour, of every bee. He set the escape crosswise of a hive-body, raised the cover-board from the crate, gave the bees three or four blinding puffs of smoke, lifted the crate of sections from the hive to the escape, and then set both in place again on the hive; then gave a little more smoke, put on the cover-board, and left them. After looking at the other bees a few moments we went back to the escape, took the case of sections to the honey-house, and not 25 bees were to be found in the case. We then looked at the under side of the escape, and found it full of bees. These were jarred in front of the hive, and the cover-board put on the section case below. Besides this deep escape he had them three, four, five, and six inches deep, and with four, five, and six cones; and I learned that his results were like my own—that the cones should not come nearer to the bees in the hive or case below than one inch; that $\frac{3}{4}$ space above the board was just right; that six cones, bringing the corner ones three inches from the corners each way, and the other two in a row lengthwise, was the best; that not less than a two-inch hole should be used in the board, and a three-inch hole is better; that a double cone is necessary, because, if

a bee on the outside can lick from a bee on the inside, they will learn the way back and forth; that there must be ample room in the escape-case below the board for the bees from the sections to cluster, and oblige them to go down the sides of the case to the hive or sections below, if you want your sections to be freed of bees quickly.

I know, from what I used the escapes in 1888, '89, and '90, that I can have the sections freed of bees so I can handle them three times as fast as without the escape; but I don't want them less than $4\frac{1}{2}$ inches deep, and I like them from 5 to 6 inches deep better. I can handle more honey alone with the escapes, and easier, than I can with a helper without the escapes. Twenty-five escapes are as good as one man to handle 100 colonies of bees when taking off sections.

Milford, Ct., Aug. 14.

H. L. JEFFREY.

Many thanks, friend J., for your suggestions. It is only by repeated trials and experiments that we can tell just what bees will or will not do in matters of this kind. Now, inasmuch as you know just exactly what is needed in this matter, can you not make them and offer them for sale?

THE MOLE CRICKET.

ITS HABITS.

The insect forwarded by you from E. W. Hammond, Lima, O., is the mole cricket. As Mr. H. says, it is a curious insect, and it is not strange that he should wish its name and habits. The technical name of this is *Gryllotalpa borealis*. The name *Gryllotalpa* really means cricket mole, which, if reversed, would be quite the truth. It is really a cricket, but is very molelike, as is at once apparent from its front legs. This insect is very common here; but as it rarely comes forth from the earth, it is not often seen. It inhabits low moist ground, and is not infrequently seen or found in cultivating or ditching in such places. All authors say, as did Harris, which the others copy, that it feeds on the roots of grass. In Northern Ohio and Michigan it has been known to eat into potatoes quite seriously, especially when planted on low ground. As the potato is only an enlarged root, it is not strange that these crickets, like the wire-worms, should desire to test their quality.

One year our students took several of these crickets from one of the rooms on the first floor of one of the college dormitories. They fly forth from the earth to mate, and I presume were attracted to this room by a female which had been brought in by the students. If these are plentiful enough to be troublesome, we must plant our potatoes on upland.

Agricultural College, Mich.

A. J. COOK.

SOLAR WAX-EXTRACTORS.

A DEVICE USED BY ONE OF CALIFORNIA'S PROMINENT BEE-KEEPERS.

Nearly every apiary in California has its "sun extractor," as they call them here, to melt up cappings and broken combs; and, so far as my observation goes, they are all built on the same plan and about the same size. It looks as though they were all made after the same pattern, without any thought of improvement. I believe they were originally made to extract combs full of honey before the honey-extractor came out; and, after the honey-extractor came, the same implement was used to melt the cappings. I think, however, that they can be greatly improved for melting cappings, and that is the object of this article. Perhaps you would like to know how the old original California sun extractor is built, so I will describe it first and then give what I think is an improvement.

The box is made of $\frac{3}{4}$ lumber, lined inside with tin, and is 58 inches long, 30 wide, 13 deep, outside measure. The glass cover is two ordinary window-sash 9x13 glass. A wooden frame inside, 5 inches below the glass, supports a sheet of perforated tin, the size of the inside of the box. The cappings are laid on this perforated tin, and, when they melt, the wax and honey run through into the chamber below, leaving what Californians call the "slumgum" on the tin above. The wax hardens immediately into lumps of every shape when it gets below the tin, and is always melted over a fire and run into cakes before sending it to market. The honey is drawn off through a tube or molasses-gate in the lower end of the box, and is usually kept for feeding. Is it not a mistake, where the A B C book says the wax is ready for market? and also where it says, "A pipe may be connected with it to run the melted wax into the inside

MCINTYRE'S SOLAR WAX-EXTRACTOR.

of a building"? Taking the wax out of these extractors, and getting it ready for market, is an inconvenient and disagreeable job, because the lumps of wax are all smeared with honey. What we want is something that will separate the wax, honey, and slumgum, and leave the wax in a nice solid cake ready for market. In order to do this the wax must not be allowed to fall in the shade of the perforated tin or zinc and cool off, but it should be kept in the sun until all is melted, when it will cool in one solid cake.

We have been experimenting a little along another line, and find that, if the cappings are laid on an inclined plane under glass, the honey and wax will run down and leave the slumgum on the inclined plane. Now, all we have to do is to have a box at the bottom of the inclined plane, also under glass, to hold the wax and keep it melted until it has all run down, when it will harden in one solid cake. To make a long story short, here is a picture that will explain better than words.

A is the inclined plane, where the cappings are put. I would make it 2 feet wide, 4 feet long, 5 inches deep. B is a piece of wire cloth to prevent any slumgum from running into the

honey and wax receptacle F, which is 2 feet square on top, tapering to 18 inches at the bottom, and 12 inches deep. The flaring sides will allow the cake of wax to be lifted out easily, and the honey is drawn off through the molasses-gate G. The space marked D will be filled with honey, and the space C with wax. E is the glass cover over all. It should be hinged on, and fit tight to prevent the escape of hot air.

Fillmore, Cal., Aug. 18. J. F. MCINTYRE.

Your ideas on the construction of the solar wax-extractor—that is, the principle of it—are correct. When I visited G. M. Doolittle I found he was using something on very much the same principle, only, if any thing, it was on a simpler plan. As I took a photograph of it at the time, I will, when an engraving is made, describe it. Yes, the wax should, as fast as melted, run down the inclined plane, and thence into a receptacle also exposed to the direct rays of the sun after thoroughly melting. We propose to modify our solar wax-extractor, so as to combine the features of the one illustrated above, and the one used by Doolittle. Both of you have made some very great improvements in the sun extractor, over the one we have been selling.—E. R.

EXPERIENCES OF THE PAST SEASON.

MRS. AXTELL GIVES US A GREAT NUMBER OF VALUABLE, PRACTICAL THOUGHTS.

Our bees thus far this season have stored but little surplus. The winter being warm they consumed the most of their stores, and came out in the spring strong in numbers; consequently we had to feed largely. The first of May found them almost wholly dependent upon what was fed them. Then came three weeks of cool cloudy weather, and they flew but little; and as Mr. Axtell and I were both feeling so poorly just then we came near letting some colonies starve; and the consequence was, they dwindled instead of increased in numbers just before the honey harvest; but by building up the stronger with brood from the weaker colonies, we had the larger part of our colonies ready for the honey harvest in June. Such colonies gathered from 10 to 25 lbs. of surplus. Those that we left unaided gathered no surplus.

Some 30 colonies that brood was taken from to build up others, have had to be fed since about the first of July, and will still need more feeding.

The drouth has been so severe as to dry up all honey-bearing plants, or nearly so. About ten days ago we had a heavy rain, and two or three lighter ones since, that have wonderfully revived vegetation, causing the little heart's-ease there was to branch and blossom out, and bees are gathering a living now. We are hoping our bees will gather enough to winter upon.

THE DIBBERN BEE-ESCAPE.

When we take off our surplus honey, as usual, there are some bees we can not get out very readily. We generally set them in the honey-room on end around on the floor, and let the bees fly to the window, and then pile up afterward. Sometimes we pile them up one super cross-wise of the other, and another lengthwise, and so on; but this time we put a Dibbern bee-escape honey-board over a weak colony, and piled up supers six or eight high, and in a few days took them off, and found the bees all gone out, or nearly so, and the colonies nicely

strengthened up. Some other weak colonies we did not use bee-escapes upon, but partly covered the colonies, and left one good passageway at one side of each row of sections, and then piled the cases up as high as we could conveniently reach, and thought it was safe, and left them on several days. Those colonies got both bees and the unsealed honey. The bees mostly went out, but not so well as those with the escapes; but it helped the colonies, and did not injure any capped honey. Although it was done at the time of a honey-dearth, scarcely any bees were killed, and I think no queens were killed. I think the latter way of getting out the bees an excellent one, especially if one has weak colonies he desires to strengthen, especially if there are many bees left in the supers. Some colonies seem to cling to the supers more than others, and it takes a long time to get them all out.

BAIT COMBS.

Our bees this summer would have stored but little honey in sections if they had not had bait combs. Many colonies filled only such combs, and put the remainder of their honey into the brood-combs below. Wise little bees! they knew better than their owner what a long drouth was before them.

I certainly would never melt up clean combs in sections, or even bits of new comb that can be fitted into sections. I think there may be a difference in localities. Bees may more readily enter the supers than in other places. It retards swarming if they may be got to work briskly in the supers before they get the swarming fever.

ITALIANS AHEAD.

This spring I noticed that the hybrids entered the surplus cases much more readily than the pure colonies; but the pure ones that did work above, gathered much the most honey. In the body of the hive the pure colonies filled every cell possible—chucked it full—while a few black hybrid colonies were very light in stores. For that one reason alone it pays to keep only pure Italians as far as possible. I am afraid I should feel like giving up bee-keeping if we could get no better bee than the blacks for these poor seasons. Good years it doesn't seem to make so much difference, except in handling. They run provokingly just where one does not want them, while the pure ones stick to the combs quietly; but the blacks must be equally hardy a race of bees as the Italians, or it would not be so difficult to keep them pure.

ARE THERE TWO KINDS OF COMMON BEES?

It does seem to me there is a difference between the black and the brown bee. While at the Aurora Cancer Hospital this spring the doctor brought home a small colony of large brown bees. The bees certainly did not look so black and shiny as the blacks of our neighbors at home. The colony was so small that I feared he would get no surplus from it this summer, and I never handled a colony of Italians that was more gentle. When working them, through transferring some of the combs and strengthening others, I threw off my veil and worked with both face and hands bare, and got no vicious sting. Only one stung me, and that I mashed. I suppose one reason they were so gentle is, I had good heavy smoke. I told the doctor I wanted some smoke to subdue them with, and he went and got a large stove-kettle and filled it half or two-thirds full of coals and chips, and set it on the side of the hive where the wind would carry the smoke over the bees. He had the colony set on the top of an eastern veranda, close up to a window

where he could watch the bees from a bedroom window, and step out of the window and care for them.

A few days ago I had to return to the hospital, as the cancer did not seem to be wholly eradicated; but I hope it is entirely destroyed now. I found the colony of bees built up into a strong fine colony, and had given something like 20 lbs. of surplus honey, but had not swarmed. It had plenty of brood and honey below in the brood-nest. I think there are not many bees kept in the vicinity where he lives, and I could not find that there was any large bee-keeper in Aurora. As there is a small stream running through the town, there is waste land covered with wild flowers, and it seemed to be a good locality for bees.

THE ADVANTAGES OF ONLY A FEW COLONIES IN A LOCALITY THAT IS NOT FIRST CLASS.

Many poor years that bees do not pay if run for honey as worked by the average bee-keeper, would yield returns, if a person kept only a few colonies and had them all boiling over with bees at the beginning of the first honey-flow. We seldom have a year but that the bees would pay their way, with a small income to their owner, above the cost of keeping, if worked on the above rule; and when a good year came they would pay largely.

VICIOUS HYBRIDS AND YOUNG CHICKENS.

Little black chickens, while very young and downy, ought not to be allowed in an apiary, especially if left to run with the hen, or confined in a coop near a vicious hybrid colony at times of the year when much work is done; but when they get older and feathered out they are very useful to gather up the roaches and moths, as the bees do not seem to sting them so badly as when young and downy. We have never had them bother white chickens, even while very young. We have two young Plymouth Rock cockerels about half grown. When I start down into the apiary they will follow me around from hive to hive picking up roaches, as there are a good many in our apiary this year. They will pick a roach out of a lot of bees that are shaken off upon the ground, so quickly that I don't think they get stung at all, and seem to enjoy the fun.

Comb honey is almost a staple article in our little town, while twenty years ago one had to work hard to sell it all. Now the principal groceries and stores all keep it the year round, if they can get it.

Cut-out honey looks very nice if cut out in square chunks and set up on edge in a circle around the outside of a new tin pan, and then the center filled in; and quite a quantity may be laid on top, and all covered over with a glass cover, such as are used at restaurants and lunch-rooms to cover cakes and pies with. One groceryman sold more for us of extracted than three other stores in sections last winter; but it was the *man* that sold the honey, rather than the shape it was in. In winter, cut-out honey will sell readily without a cover. As soon as it gets to looking mussy, and the unsealed and liquid honey candies, we take in a fresh panful, and buy back all that was left in the pan.

In leaving honey in stores, especially in the warm weather, the cover should fit so closely that dust and flies can not get in, else it becomes unsalable in a short time, and grocery-men get disgusted with it, and do not care to handle it. Sometimes bees, also, find it if not tightly covered, and soon fill the grocery so that people are afraid to enter, and so the groceryman loses trade for an hour or two, and concludes that handling honey won't pay. When bees get to entering a grocery they hang around the door. Such was the case some years ago in

one of our grocery stores in Roseville, where we had our honey.

CHICKENS OR BEES, WHICH?

In looking over a back number of GLEANINGS the question is asked, "Which pay best?" We should say, "Bees, in the long run, counting several years together." Poultry is usually a source of profit every year; and every month in the year, with careful handling, it might be made to be profitable; but when we do get a good year for bees they are very profitable, and bring in a large income—so much so we see many people attracted to the pursuit only to give it up, perhaps the next year, in disgust. So it is those who have perseverance that make bee-keeping pay best; and then I think we get too many bees in a neighborhood, especially where all waste lands are tile-drained, as is the case here.

A SWARM OF DRONES.

Last summer, between four and five o'clock, while I was still out in the apiary watching for swarms, I heard a loud humming of bees just above my head. I looked above me, and all about me was a swarm of drones. Scarcely any workers could be seen among them. They flew round and round in a circle some ten minutes or so, and then all at once seemed to scatter, not settling like a swarm.

IS EXTRACTED HONEY INJURED BY BEING STORED IN OLD BLACK COMBS?

Why would it not be a good plan, when desiring to use old combs for extracted honey, to bleach them somewhat by filling them with water and letting them stand a few hours, and throw out the water by extracting them. I did so at one time with a few combs, and the water thrown out was nearly as dark colored as coffee. If the water would be colored by dark comb, I should think honey also would be.

WINDBREAKS FOR BEES.

I don't think we sufficiently value windbreaks for bees. If wintered out of doors they are invaluable. We could see a great difference in the loss of bees in wintering just as soon as we had erected a high board fence, 7½ feet high on the east, west, and north side. It does not make the apiary much warmer in the summer, as we feared it would, because, in hot weather, the wind nearly always blows from the south or southwest or southeast, and then it blows into the apiary. If it blows from the north or northwest, or northeast, generally the weather is cool, and it makes no difference if it does not blow into the apiary. If the bees are wintered in the cellar, and are set out upon their summer stands with a windbreak, even if packed with chaff the wind pierces the cracks in the hives, and chills brood in small colonies, while the bright sunshine at the entrance invites the bees to fly, and the cold wind so chills them that they never return.

Ernest mentioned, last winter, that he had no trouble in keeping his 40 colonies of bees cool enough in his cellar; but if he had added 40 colonies more, he would have seen a great difference in temperature; and if he had made it 150, even if the cellar were as large again, he would have seen it almost impossible to keep them quiet such a winter as the last.

With proper windbreaks, bees may be taken from the cellar very early in the spring, and set on summer stands, and do even better than left in late, especially where there are many bees left in the cellar. The remaining ones will do better also. We choose that part of the apiary where the winds are broken off by buildings, to set out our first colonies, and lay on top of the hives an extra quilt, and lean up against the front of the hive a board on cool days.

Colonies taken out the first of March will need from 5 to 10 lbs. of honey per colony to spring them, more than colonies left in the cellar until the middle of April; but they will be stronger colonies the first of June if they are provided with that much more honey, and properly protected from high winds; and being stronger colonies they will gather more than the 5 or 10 lbs. of honey per colony, more than the ones set out later.

It seems to me it might be easily tested whether colonies of bees gather more honey or less, by having their queen taken from them or caged during the honey harvest or swarming time, by placing several colonies upon separate scales, one half by having the queen removed or caged, and the other half retaining their queen.

BEEES DYING IN JUNE.

Just after the first few days of honey-gathering from white clover, the first of June we had three days of high winds. On the third day, and for several days thereafter, our bee-yards were literally strewn with dying bees. A few fair colonies were reduced to one or two combs of bees. Two small colonies lost all but the queen and a few young bees—not enough to cover a comb. Strong colonies did not seem to be affected in the least. We could not think what could have caused it. If it had been the wind alone, all would have been alike affected. We concluded it was the large honey-flow. The few old bees in the hive, finding they had a great amount of brood and young bees to labor for, actually worked themselves to death, and could not withstand the high winds.

Roseville, Ill., Aug. 23. MRS. L. C. AXTELL.

Why, my good friend, you have given us a wonderful array of practical thoughts and suggestions; but it throws a shade of sorrow over it all when we learn that you are afflicted with cancer. May God grant that the hospital you mention may have skill and wisdom to fight successfully against the dread disease.

You say the colonies, from which you took brood had to be fed about the first of July. Now, are you sure that those which *received* the brood were benefited enough more to pay?

We have practiced the very plan you mention in regard to getting bees out of the supers, by setting them over a weak colony; but we never noticed that they could be made to take out the unsealed honey. I think that, perhaps, unless the honey were removed at just the right time, they would be quite apt to take some of the *sealed* honey also.

The testimony in favor of bait combs seems to be pretty conclusive; but is it not true that some sections that have perhaps been tried one or two seasons became obnoxious to the bees? I know that we had some that we put on year after year in time to get them full. The bees would fill new ones containing foundation; but these old ones were finally thrown away. They were of different pattern, so we recognized them at sight.

Are you not a little severe on the hybrids because they do not keep enough honey in the brood-nest for wintering, as the Italians do? Many of our large honey-producers would be glad to have every drop of clover honey put in

the sections. Of course, they would have to keep watch of colonies that do this, to prevent them from starving; but I think it would pay well for the time required.

Although you do not say so, I presume the brown bees mentioned are found somewhere in your State of Illinois. Now, if there is really a difference, why were they not crossed and re-crossed years ago? I can hardly think it is any thing more than accidental. I have seen some colonies of blacks that were very gentle; and I have seen them, too, that were brownish colored instead of black. Where great numbers of young bees hatch out at once, when they become of the right age they have a much brighter look than older bees.

We have never known bees to sting chickens, but it has been reported once or twice.

Your remarks about looking after the honey at the groceries are excellent. In no other way can a honey-trade be built up.

Your suggestion, that *tile draining* is bad for *bee-keepers*, is a big point in favor of good farming, even if it is bad for the honey-crop. Our farmers who raise weeds will take the hint.

Your suggestion, that old combs *may* color the honey, is a good one.

We agree with you in regard to windbreaks.

In regard to bees dying in June, so many such reports have been received we think there must be something in it besides a lack of stores. I have sometimes thought, as you state it, that the labor demanded by the growing brood is so great as to wear out or kill the nurse-bees by overwork. Is it not strange that bees, with their wonderful instincts, should so many times behave themselves much as human beings do?

RAMBLE NO. 29.

STEBEN CO.

Haskinville is a town in Steuben County, noted for its wooded hills and fossil rocks. One is more impressed with the grandeur of the scenery as we enter the county than we are after we get in. The borders are cut up with deep winding ravines and picturesque glens—just the county for camps of brigands. But our traveling companion was a very honest-looking young man, and we trusted to his guidance. Our team waded patiently through the mud, and at last reached the enterprising village of Haskinville. The enterprise all seemed to be centered in one store conducted by George and Ziba Silsby, and a little Wesleyan church, conducted by Rev. Mr. Clow. We found the Silsby Bros. working heart and hand with the minister, and evidently having a good influence in the community. They seemed to be very conscientious in their dealings, and kept nothing that savored of alcohol, and had even stopped the tap at the little hotel near by. After considering the influence that tobacco has upon the cleanliness and morals of people, they had also thrown up a good trade in the weed, and seemed to be making a good living without its revenue. It was no little wonder to us to find them holding the postoffice, and dispensing the mail under a Republican adminis-

tration, when they are both ardent Prohibitionists; but we believe these young men will not lower the standard of principle, even if they do get turned from office.

SILSBY BROTHERS' STORE.

We saw here for the first time in many weeks the familiar face of GLEANINGS at the residence of Henry Sprague, who is a veteran in the bee-business, having now about sixty colonies. Mr. S. uses a side-storing hive, but was not satisfied with it, and was studying the Dovetailed hive and a non-brace-comb wide thick top-bar, with a view of adopting them. His experience with very narrow top-bars had given him much trouble by bees filling up between with not only brace-combs but with great daubs of comb and honey. Sixty colonies was the limit of his field. Extracted honey was raised to some extent, and thrown out with an old-style Gray & Winder machine. His Bingham smoker was an ancient one, twelve years old, and good for a few more puffs. Cellar wintering is practiced; and while most bee-keepers put clean sawdust upon the cellar-bottom, Mr. S. had a good depth of straw. We concluded, all to ourself, that he had an excellent material for mice-nests, and we kicked around rather unnecessarily to wake 'em up, when, "dunder and blixen!" how we did commence to sneeze!

The grip was the main occupation of people generally just then. We had heard of some very sudden attacks, but had thus far escaped; but we thought we had it sure this time. We had relied upon a large chunk of camphor as a sure preventive, and got it to our sneezing-apparatus as soon as possible. This prevented further external explosions; and while we were allowing the internal feelings to subside, Mr. S., who had followed our sudden exit from the cellar, said I was afflicted with cayenne pepper instead of the grip.

"Cayenne pepper!"

"Yes. That straw you kicked around so is sprinkled full of cayenne pepper. I put in straw

and pepper every fall to keep the mice out. If they get into that straw they sneeze just as you did—ha! ha!—and get out about as fast as you did."

We found Mr. S. and family also earnest workers in the aforesaid Wesleyan church, and a family of influence for good in the community.

Willard Collins is another young bee-keeper in this town, and it was in the large forest near his father's residence we photoed the bee-hunters' camp. Will, with the ax, has his eye on a bee-tree, and the other fellows are ready for a slice of bread and honey. These forests are filled with just such trees as bees delight to live in.

Ira Bowen, of the town of Fremont, the honest-looking young man who conducted the Rambler safely into this region, is also a bee-keeper, and a keeper of a maple-sugar bush. The family is sweetened at both ends of the season, and, of course, they are sweet the year round. The Rambler was fed on maple in all shapes, and believes that Steuben County can produce a product equal to or even superior to all others. Ira uses the L. hive and packs with straw outdoors; and, though having a small apiary, he has been successful with it. His sister Alice helps to a certain extent, but it is mostly advice, for her first experience and attempt at hiving bees gave her a severe lesson as to the deceitfulness of the busy bee. Ira and the boys were busy on a remote part of the farm, when a swarm of bees came out. "Now," says Alice to her mother, "is my opportunity. This is the chance of my lifetime to show what women can do with bees. The *Chautauquan* says that bees will alight every time on an elevated mullein-stalk."

Obtaining one she held it aloft among the bees, but they gradually drifted around the corner of the house, out of sight. She held on to the mullein, however, for half an hour, more or less, thinking they would come back in good Chautauquan order. Of course, her arm pained her not a little; and, being an experienced schoolteacher, her heart went out in sympathy to those refractory urchins she had punished by making them hold up a stick of wood. Her reverie was, however, broken by her mother calling from the window, "Why, Alice, what are you holding that mullein-stalk up there for? The swarm has gone back into the hive long ago." That mullein-stalk was dropped like a hot potato, and Alice now believes there is nothing but deceitfulness in the busy bee, which opinion is shared in, more or less, by the

RAMBLER.

DID THE BEES STEAL THE EGG?

TWO OLD QUEENS IN THE SAME HIVE. AND LAYING PEACEABLY.

In GLEANINGS for Aug. 1, page 568, you say you think it doubtful whether bees will steal eggs from another hive. Let me give my experience. I had a colony of blacks which I wanted to change to Italians. After killing the old queen I waited one week, then took out all frames and gave them frames with foundation, with the exception of one frame that had some comb which I had fixed up according to Alley's plan, with 10 or 12 eggs in it. The bees built out two very nice queen-cells; and a couple of days before they hatched I looked them over, and just alongside of one of the capped queen-cells was another queen-cell just started, with an egg in it. Now, where did that egg come from? I am positive there was no queen in the hive nor any fertile worker, as the

WILLARD COLLINS' BEE-HUNTERS' CAMP.

cells hatched, and in due time the young queen was laying. One egg was all I could find.

Another thing I should like some information on: This summer I have been requeening all colonies which had old queens. One day, after catching three or four old queens, out of curiosity I dropped one at the entrance of a strong colony which I knew had a laying queen. She walked right in, apparently undisturbed. Ten days later I examined this hive and found two old queens laying for all they were worth.

I am positive both were old queens, as both were clipped (I keep all my queens clipped). I do not think they had tried to supersede the old queen, as there was no sign of it, and she was laying well. Is not that somewhat out of the usual order of things? FRANK W. LIGHTON.

Williamsport, Pa., Aug. 12, 1890.

Friend L., I am not quite satisfied that the bees stole that egg. You do not make it quite clear, however. Did a good young queen hatch out from that egg that came into the hive so mysteriously?—Letting a queen loose at the entrance of the hive where they have a laying queen, without her being harmed, is nothing very strange, after all. If you have a dozen queens you don't care any thing about, and you put them at the entrance of other hives during the honey season, I think you will find a half or more of them will be received and go to laying, and you will find the two queens in a hive, probably, until the honey-flow ceases.

INTRODUCING.

DR. MILLER'S METHOD WHEREBY IT CAN BE ACCOMPLISHED WITHOUT EVEN OPENING THE HIVE.

The plan of introducing queens by means of the Peet cage, letting the bees eat through the candy, thus liberating the queen, presents some advantages over any other method I have tried. It is especially advantageous in an out-apiary. Kill your old queen, put the new one caged in the hive, and if you don't look at her again for a week it doesn't matter. But the Peet cage doesn't work equally well in all hives, for the simple reason that there is not room for it. My hives have flat board covers, so there is not room between the top-bars and cover, and the only way to do is to put the cage between the combs, which spaces them so far apart as to make trouble.

MILLER'S INTRODUCING-CAGE.

I send you herewith a simple introducing-cage that I have been using this season with a great deal of satisfaction. It is not a shipping-cage, of use only for introducing, but it takes up so little room that, if left between the top-bars or combs for a year, no great harm would be done. Generally, however, I push it into the entrance of the hive, under the bottom-bars, and prefer this unless it is so cold that there is danger of chilling the queen. It is so simple that any one can make it.

Take a block 3 inches long, $1\frac{1}{4}$ wide, and $\frac{3}{8}$ thick; two blocks 1 inch by $\frac{1}{8}$ x $\frac{3}{8}$; two pieces of tin about an inch square; a piece of wire

cloth $4\frac{1}{2}$ x $3\frac{1}{2}$; two pieces of fine wire about 9 inches long, and four small wire nails $\frac{1}{2}$ or $\frac{3}{8}$ long. That's the bill of material. Lay down the two small blocks parallel, $\frac{3}{8}$ of an inch apart, one piece of tin under, and one over them. Nail together and clinch. These two blocks, being $\frac{3}{8}$ inch apart, make the hole to fill with Good candy, through which the queen is liberated. A good way to make sure of having this hole all right is to lay between the two blocks, when nailing, a third block $\frac{3}{8}$ square. Put this nailed piece at the end of the large block, and wrap the wire cloth around it, letting it come flush with the end of the small piece, and it will come within about half an inch of the end of the large piece. Wind one piece of wire within about a quarter of an inch of one end of the wire cloth, and fasten by twisting, and wind the other wire at the other end. Play the large block back and forth a few times, so it will work easily in the wire cloth, and trim off the least bit of the corners at the end of the block so it will enter easily. To provision it, let the large block be pushed clear in; fill the hole with candy, and tamp it down. When to be used, after putting in the queen, push the block in far enough to allow the queen a room about $1\frac{1}{2}$ inches long. After the bees have had it for some time it will be so glued that the plug must be scraped off before using again. There is nothing brilliant about this cage, and nothing really original, but it has the merit of such simplicity as to be easily made by any one, and of being of such size and shape as to be used where others can not well be used.

BAIT SECTIONS FINISHED FIRST.

This year I had some 250 of last year's unfinished sections used as bait, one in a super; and after the general report that such sections were filled first and finished last, I was quite interested to notice how mine would come out. Invariably these bait sections were commenced first, just as reported. And almost as invariably these sections were the first ones in the supers to be finished. I think there were two or three of the 250 that were not first completed. Moreover, they are nice sections, but not quite so nice as the others. Now, why is it that the general agreement has been that such sections were last in being finished, and would better be thrown away? The only reason I can guess at is, that some honey, if only a little that was granulated and dried, was left in the sections. When I first used bait sections I thought there must be some honey left in them, and such sections, when finished, had a watery appearance, especially after being taken off the hives for some time, when the honey was inclined to ooze through the cappings. I suspect the old honey, perhaps a little soured, acted somewhat as yeast. At any rate, I should not like to get along without bait sections; but they must have no honey in them, and must be cleaned out thoroughly *by the bees*. C. C. MILLER.

Marengo, Ill., Aug. 16.

Your cage is not really original, as you say; but a few old things, doctor, when revived in a little different form, oftentimes prove to be more valuable than the new. I know your cage will work all right, and, so far as introducing alone is concerned, it is perhaps better than any thing else—yes, even better than the Peet, when the apiarist desires to introduce his own stock into other hives on account of the great saving in time. Introducing by sliding the cage into the entrance during warm weather would work all right. I should

think. You will observe in the article below what I say in favor of the Benton cage.—We are glad to get the facts in regard to unfinished sections. So far as I remember, it seems to be generally agreed that unfinished sections that have no honey in them are valuable. E. R.

RECENT DEVELOPMENTS

CONDUCTED BY ERNEST R. ROOT.

SHIPPING QUEENS.

I have been aware of the fact for a year or two, that the Peet cage, though eminently successful for introducing, was far from being satisfactory for mailing queens. In view of this, for over a year back, in our queen department we have been testing different cages; and finally, during the latter part of last season, and the whole of this, we have been sending over half of our queens in the Benton. This is the cage that our friend Frank, now of Munich, Germany, first introduced for mailing queens across the ocean, and those who have received queens by mail from Mr. Benton can testify to the remarkably good condition in which the queens were received, although they have come from Germany, across the ocean, and then across our own continent in some cases. I have felt that perhaps there might be a good many queen-rearers who were neglecting to avail themselves of a good thing, and hence I am glad, after a most thorough test, to mention it.

As Mr. Benton did not originally design it for introducing, however successful it might be for mailing queens across the continent, it would hardly be suited to our purpose unless it could be so adapted. It took very great ingenuity to modify it, as the engraving below will show.

BENTON'S MAILING-CAGE, AS USED AT THE HOME OF THE HONEY-BEES.

The figure on the left shows the block as bored out ready for the reception of the bees and candy. Its outside dimensions are $4\frac{1}{2} \times 1\frac{1}{2} \times \frac{3}{4}$. Three holes $1\frac{1}{2}$ in diameter, by $\frac{3}{4}$ deep.

tion, while the center one has no opening except a communication through the end hole. A piece of stout manilla paper covers the center and candied hole, and then wire cloth covers all three. The feature of this cage is, that for warm weather the bees can seek the end hole, with ample ventilation through the saw-cut in one corner, and by the wire cloth which has a direct communication from the outside. For cold weather, or when the bees, perchance, go over the mountains, they will naturally huddle into the center hole, where it is warmer. To introduce, simply follow directions which we print on the nice clean basswood cover, as seen below:

The hole through the wire cloth, through which the hive bees eat to the candy, will be seen in the cage near the center. To put the queen into the cage, the wire cloth is slid back, and the bees are picked up individually, one by one, by the wings, until twenty or thirty have been put in, the number depending upon the weather, after which the wire cloth is tacked down. The cover, with printed directions as below, is tacked over the cage covering the wire cloth, with four half-inch wire nails. To mail, with a coarse pen we print the directions in a neat back-hand lettering, which most of the clerks in the office know how to do. A two-cent stamp is then put on at the right, and the cage is ready for California or any other remote point in the United States, without wrapping or string.

The almost universal testimony of our customers is, that the queens arrive in these cages in splendid condition. Whenever a Peet cage fails to deliver the queens, they are always replaced in the Benton. With the exception of two or three instances (when we put in only three attendants) during our large queen-trade this summer and part of last, it has been successful. Its great superiority in mailing, over the Peet, has been so very marked that we have about decided to use it entirely next season. As to the comparative merits of the two, the card below speaks for itself. It seems we had sent our customer some queens in the Peet cages. They, failing to go through, were replaced in a Benton cage, and this is the way our customer wrote:

The queens came this morning, no dead bees in either cage. They were just as lively as when you took them from the hives. I don't want any more queens in the Peet cage. E. D. HOWELL.

New Hampton, N. Y., Sept. 6.

Not long ago we sent twelve queens in Benton cages to Reno, Nevada. Our customer, Mr. W. K. Ball, writes of their condition as follows:

Directions for Introducing with the Benton Cage.

Before introducing, be sure that the colony is queenless. A colony long queenless is not so good as one lately so. To introduce, pry off the cover, and note the condition of the queen. Lay the cage under the enamel cloth or quilt, on top of the frames, directly over the cluster, wire cloth down. If the weather is cold, insert the cage between the frames in the cluster. In 24 or 48 hours, by means of the opening to the candy through the wire cloth at one end, the bees will eat through the candy, when they will be ready to accept the queen. Unless the queen appears feeble, do not examine again for 48 hours. If she is not yet released, and is in good condition, close the hive up again. The bees will shortly release her. The point is, the bees should release the queen themselves. While this method gives general success, we can not guarantee safe introduction. We only guarantee delivery of a queen alive and in good order. If the queen is dead upon opening this package, notify us at once and we will replace free of charge.

A. I. ROOT, Medina, Ohio.

are bored just close enough to leave an opening from one to the other. The further one is filled with candy. The other two are for the bees. The end hole provides an abundance of ventila-

The twelve queens all arrived O. K. They are very nice. W. K. BALL.

Reno, Nev., Sept. 15.

Mr. J. D. Fooshe, who has had remarkable

success in mailing queens, not only in the Peet but in the Benton cage, says:

Nearly all I sent out single were in Benton cages, and generally long distances. I think my success this year has been remarkable. I think the Benton a better shipping and introducing cage than the Peet, and will give better satisfaction.

Coronaca, S. C., Sept., 1890.

J. D. FOOSHE.

Mr. Fooshe is a queen-breeder of no little experience. He has furnished us this season over 300 queens. We have received scores of testimonials, but we give the above only as samples. It is not practicable with us to send queens in single Peet cages to California.

As to introducing, the candy plan, with our customers, seems to have given fairly good results. The Peet method of introducing is certainly better where the queens arrive in feeble condition, because they are then caged right on to a comb, and are given access to cells of unsealed honey; but the Benton seems to deliver the queens not only alive but vigorous, and the candy plan is just as good for introducing good strong queens. All the timid beginner needs to do is to pry open the cover and lay the cage down upon the frames, and introducing, so far as *he* is concerned, is done. With the Peet plan, the A B C scholar may be nervous for fear he may not be able to draw the slide just right, and successfully cage her majesty on the combs, without pinching her head or letting her get away.

There are good reasons why the Benton cage delivers its queens in better condition. First, it is, to a certain extent, climatic. If the temperature, in going over the mountains, we will say, suddenly goes down, or the night turns cool, the queen and her attendants can go into the warmer compartment of the cage. If, on the other hand, it goes up, they can enter the end hole. With the Peet cage there is one large hole, one side of it covered with tin. The metal itself is cold, and readily conducts away the heat of the few bees and queen. Aside from this, as the mail-bags are often thrown with considerable violence from the cars, the concussion of the cage causes the bees to be jarred from one side of the compartment to the other, in the Peet cage, especially if they happen to be on the tin side of the cage; and a large compartment is much worse than a small one. Again, the tin slide is always invariable in width; and the wood itself, if it shrinks or swells, will cause the slide to work either too loosely or too hard. It would seem that, theoretically and practically, there are good reasons why the Benton cage is superior as a general mailing-cage. Our friend Mr. Benton deserves much credit for introducing it. I notice that one or two queen-breeders who are sending out queens in identically the same cage are calling it after their own names. Possibly they do it through ignorance. But Mr. Benton, I think, was the first to construct this kind of cage, and demonstrate its great utility for mailing queens, not only across continents, but across oceans, and it should be named after him.

CONVENTION NOTICES.

The Southwestern Wisconsin Bee-keepers' Affiliated Association will meet Oct. 8, 1890, in Platteville, Wis., at the residence of E. France, to commence punctually at 10 A. M., sharp. There will be a large turnout of prominent bee-keepers of the State. A question-box, free to all, in which any subject you wish discussed can be presented and answered. Let every one be on hand and bring in his report for 1890 starting at spring count, or May 1.

BENJ. E. RICE, Sec'y, Boscobel, Wis.

The International American Bee Association will meet in Keokuk Ia., Oct. 29, 30, 31. Parties desiring to attend will obtain a programme, and hotel rates, by addressing the secretary. Further particulars will be given in the Oct. 15th issue. A large attendance is expected, as this is the first meeting of this association west of the Mississippi, and a number of the leading bee-keepers and bee-publishers have promised to be present. For further particulars, address

C. P. DADANT, Hamilton, Ill.

The next convention of the Turkey Hill Bee-keepers' Association will take place at the Turkey Hill Grange Hall, near Wildermon's Station, three miles southeast of Belleville, Ill., Oct. 30, 1890. All interested are invited. S. BRANTINGHAM, Treas.

ADVERTISEMENTS THAT DO NOT PAY.

SOME OF THE REASONS WHY THEY DO NOT PAY.

A. I. Root:—I will settle that advertisement, which, by the way, never brought me one inquiry.

J. B. LAMONTAGUE.

Winter Park, Fla., Sept. 15.

On looking up this advertisement that did not pay, we find it read as follows:

VIRGIN QUEENS. Pure virgin queens at 50c each, or 40c each per 100.

J. B. LAMONTAGUE.

Winter Park, Fla.

Now, when advertisements of virgin queens began to come in, I told Ernest that I had so little faith that they would be of value to anybody, I would advise not accepting them. If I am correct, he suggested, however, to let people try them and see what the reports would be. Well, the above report is just what I expected, and, in fact, what I am glad to see. The subscribers to GLEANINGS, to a man, have sufficient good sense to refuse to invest. I do not wish to be severe on those who have recommended sending virgin queens by mail. One who is very anxious to succeed could introduce a virgin queen, and get her to laying; but I think he would get along much faster, and with much better success, if he had queen-cells instead of queens; and I am not certain but that I should prefer to take larvae of the right age rather than a virgin queen that was old enough to have made a trip by mail. Friend L., we take pleasure in crediting you with \$1.20, which you wasted in advertising virgin queens.

ANOTHER ADVERTISEMENT THAT DIDN'T PAY.

I advertised my bees Aug. 15 and Sept. 1, 1889, and made no sales. Now, I paid this willingly, and did not consider you responsible in any way because I did not sell my bees. However, inasmuch as it is your own proposition to refund the money thus paid, and considering the fact that you have done so by others, you may place to my credit the amount paid you at that time.

B. T. BLEASDALE.

Warrensville, O., Sept. 12, 1890.

Friend B., you give us only another evidence that almost no one wants to purchase bees after the honey crop is over, especially in our locality. We are losing some money in this business of paying back; but, never mind; we are gaining in an experience that is valuable to ourselves as well as to our readers. But, just hold on a little. Here comes some testimony from the other side.

ADVERTISEMENTS THAT DID PAY.

Mr. Root:—Please stop my advertisement at once. My queens are all sold. Your journal is a first-class advertising medium. I will patronize you again soon.

F. H. PETTS.

Warsaw, Mo., Sept. 9, 1890.

I have sold 219 queens from my advertisement. Many thanks.

J. W. TAYLOR.

Ozan, Ark., Sept. 13, 1890.

My sales are amounting to a little over \$100 per month, as a result of my ad. in GLEANINGS.

Morgan, Ky., Aug. 25.

J. P. MOORE.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

QUESTION 169. *1. Is there any advantage in having honey stored during clover bloom for stores? 2. Which do you prefer for winter—early honey, late honey, or sugar syrup?*

1. Yes. 2. Early honey.

Illinois. N. W.

DADANT & SON.

1. I think not, in my locality. 2. Sugar syrup first, and second, I have no choice.

Michigan. S. W.

JAMES HEDDON.

1. No, not according to my experience. 2. All are good. I think my bees winter best on honey gathered from the linden-tree.

New York. C.

G. M. DOOLITTLE.

No. If all are good, the one that is cheapest. We have often wintered our bees entirely on fall honey, and they wintered well.

Michigan. C.

A. J. COOK.

1. There surely is, if clover is the only source from which honey is gathered. 2. Sugar syrup; but my bees wintered splendidly last winter on fall honey.

Ohio. N. W.

A. B. MASON.

1. I think there may be. 2. I believe I should prefer the early honey, because it is more sure to be well evaporated, and the bees have all the time needed to fix it up just as they want it.

Illinois. N.

C. C. MILLER.

1. There is no advantage in keeping the best clover honey for winter stores. 2. Fall honey is the scape-goat, but not the cause of winter losses. Fall honeys are first-class winter stores, and better than sugar syrup.

Ohio. S. W.

C. F. MUTH.

In our location we have no fall honey that we can depend on for winter stores, so we always let the bees store basswood honey for winter stores. I have never used sugar syrup for winter feed.

Wisconsin. S. W.

E. FRANCE.

1. Yes. The advantage of having a better quality and better ripened honey. 2. I am a little prejudiced in favor of the sugar. I consider it as good as well-ripened early honey, and perhaps no better.*

Ohio. N. W.

H. R. BOARDMAN.

1. Very likely there is; but the plan will not do for localities where the yield per hive is small. 2. I have had no experience with syrup, but presume it to be better than most late honey, and not so good as the best early stores.

Ohio. N. W.

E. E. HASTY.

1. Not here. In fact, I think I should prefer our fall honey to clover, as a rule. In some localities, clover honey would probably be better. 2. Good honey, when the bees gather it, whether early or late. If feeding is necessary, use sugar syrup.

Illinois. N. C.

J. A. GREEN.

1. I would give the preference to honey gathered in the height of the season; but there is hardly enough advantage, ordinarily, to justify the necessary trouble in securing it. 2. My experience from feeding syrup from good sugar (31 bbls. in one season) would make me favor sugar to any honey, or as good as the best of honey.

California. S.

R. WILKIN.

1. Yes, at present prices of honey in a locality where there is no fall or late harvest of dark honey. 2. I think sugar syrup, one year with another, is preferable. Yes, early honey is good; late honey is all right in an open winter where bees are wintered on summer stands.

Vermont. N. W.

A. E. MANUM.

None, except you would be sure of well-ripened honey. Honey gathered later in the season, if thick and capped over, is probably just as good. My order of preference is as follows: 1. Good thick honey, sealed over; 2. Sugar syrup; 3. Late honey, some unsealed; 4th and meanest, "bug-juice."

Illinois. N. W. C.

MRS. L. HARRISON.

1. Yes. 2. I prefer good honey, whether early or late. For the two last falls I have fed some colonies varying quantities of granulated-sugar syrup. The amounts varied from 2 lbs. up to 20, and the quantity fed was carefully marked upon each hive. Soon after taking them out in the spring I have carefully examined them, only to find them to average no better than those unfed.

New York. C.

P. H. ELWOOD.

1. Yes, if you can get good clover honey and save it for winter stores. You have the advantage of being sure of it. You might get as good later, but are not certain of it. 2. We generally save basswood honey enough to winter our bees till we see whether we get fall honey. Any honey gathered from flowers when the weather is warm and dry will winter bees. Honey-dew, or secretion from plant-lice, is what we most dread here.

Wisconsin. S. W.

S. I. FREEBORN.

1. This depends upon your locality. Here it is an advantage to have winter stores gathered early. 2. I prefer the early honey. Our late honey-yield is very uncertain. We have but little buckwheat, and bees are liable to store honey-dew. In such cases it is a real comfort to have several frames of early honey to substitute for the honey-dew. Those living in a buckwheat-growing country, and who are reasonably sure of a yield from that source, can depend upon it for wintering. It is a good winter food. Sugar feeding in this State and in Vermont is a practice of the past.

New York. E.

RAMBLER.

The general impression seems to be that clover honey, as a rule, is but little if any better than other honey well ripened and sealed up in the combs, although one or two suggest that the man who makes sure of surplus combs to provide destitute colonies will be less likely to let his bees starve for want of attention. These extra combs, carefully set away, make the matter of feeding a comparatively easy one. It does seem, however, too bad to use our best honey, when dark honey will answer almost if not quite as well. If, however, one depends on fall honey, and does not get any, he is quite apt to neglect them, and to suffer loss. Rambler suggests that sugar feeding in York State is a practice of the past. I suspect this is largely due to the fact that honey—especially fall honey—has for some time been rather low, and good sugar rather high. To prepare and feed sugar syrup is more trouble, and there is always more or less loss in getting it into the combs and sealed up. Those who have undertaken to

throw out honey that was already in the right shape for winter stores, and supply its place with sugar syrup, have found out to their sorrow what it cost to make the exchange.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

IS THE GARDEN PARSNIP OF MISSOURI THE SIMPSON HONEY-PLANT OF THE A B C?

On p. 120, A B C, there is an illustration of the Simpson honey-plant that is as much like our common garden parsnip as two black-eyed peas. Any way, how is parsnip for a honey-plant? Ten or fifteen years ago we let some go to seed, and it came up next year in the fence-corners, and in a little out-of-the way place, and has kept every thing crowded out, and has not degenerated to this day. In blooming time it is literally covered with bees, sweat-bees, dirt-daubers, lightning-bugs, etc. You can see the honey on the little pods, with one eye shut. I think if that man on page 254 of the A B C were to see it some morning, he would turn a double summersault backward. This spring it crowded the path my wife used in going to the garden; and in order to get rid of it and the bees she took a mowing-blade and cut off the tops. She is not afraid of a mowing-blade or a hoe-handle. When it had been in bloom quite a time, and where it was cut off, it threw out another set of branches and blooms, and gave the bees a second crop to work on.

J. D. WHITTENBURG.

Marshfield, Mo., Aug. 25.

Friend W., this is a little singular. We raise parsnip seed ourselves, and have for some years, but I do not remember of having ever seen a honey-bee on the bloom. I think you are mistaken about the Simpson honey-plant being like the parsnip. If you have the two side by side you will see; but if parsnips should produce honey, somebody should locate near where parsnips are grown for seed on a large scale.

A BIG TESTIMONIAL FOR THE DOVETAILED HIVE AND THE SECTION-HOLDER SURPLUS ARRANGEMENT.

I will try to get the honey ready to ship by the middle of September. The bees are gathering honey very fast now, and the prospect is good for a month yet. The second crop of alfalfa is in full bloom now. I haven't help enough to keep up with my work. It is hard to get any one here to work with bees. Everybody seems to be afraid of them. I have one man to help me. We took off over 1200 lbs. of very nice honey today, mostly out of the Dovetailed hive. This hive, with section-holders, is the best one that I ever saw. If I had had all my bees in those hives I should have secured a third more honey this year. I see but one fault with them; that is, the bottom-bar. If the section-holder is too light it sags down when it is full of honey, and leaves too much space on top of the section, and the bees store in honey. I shall want 500 of the Dovetailed hive this fall.

W. K. BALL.

Reno, Nev., Aug. 31.

Thanks for your kind words for the Dove-tailed hive. We note your criticism, and expect to make the bottoms of the section-holders a full quarter-inch hereafter.

CAN WE KEEP BEES AWAY FROM NEIGHBORING WATER-TROUGHS?

Is there any way I can keep my bees away from my neighbor's well? They keep water in a trough for their stock. I have tried all I know, but still they go there. I have 45 good strong colonies. They are about 200 feet from the well.

JOHN BURR.

Braceville, Ill.

I presume, friend B., a good many of our readers will ask what harm the bees did, any way, at the neighbor's well. But I presume the trouble is, they are afraid of them, and imagine the bees came there to sting. It may be, too, that the children get them on their clothing, or possibly pinch them by accident; and as the neighbor feels annoyed, something should be done. Well, the only thing you can do is to provide as good a watering-place for the bees near home; and I would do this, even if it necessitated digging a well of my own. Then cut away all the trees or any thing else that keeps the sun away, and provide a lot of pebbly gravel for the bees to alight on while they are drinking. If you wish to make it handsome, put in some stones and shells. Fix in, also, some varieties of moss, and I think you can run a successful opposition to your neighbor's well. The reason I recommend a well is because nothing else, unless you have a running spring, will afford such a constant supply of just about the kind of wetness that bees prefer.

BEESWAX FOR MAKING SCREWS AND NAILS PENETRATE WOOD.

Did you ever try putting a little beeswax on a screw or nail that you wished to drive into hard wood? If not, it will be a revelation to you.

S. T. WALKER.

Forest Grove, Or., Aug. 11.

Friend W., what you mention is known to some extent, and has been, I think, before given in our back volumes. It is a very valuable fact. Some time ago we purchased a new and expensive machine for punching holes in our A B C books for wiring the paper-covered ones. The machine could not be made to work. There was not power enough in the thing to push the awls through such a great quantity of stiff hard paper. One of the girls, however, suggested that we first push the awls through a very thick sheet of beeswax. I do not know where she got the idea, but, presto! after they had been waxed they went right through the whole book without any trouble at all.

ALLEN'S HIVE-STAND.

I like your plan of an apiary, with a grape-vine trellis at the south of each hive, very much; but I think I have an improvement on the foundation of the hives. I use a platform $2\frac{1}{2} \times 4$ ft. in size, made of $\frac{3}{4}$ lumber, nailed the short way, on two 2-inch-square cleats. This platform is set in the ground so that the top is level with the lawn. The hive is placed in the center from side to side, and six inches from the back, leaving, with the hive I use, about 12 inches in front. The advantage it has is, that it will not blow away in a strong breeze, as the

sawdust or sand you use is sure to do in our heavy winds. The grass and weeds will be effectually stopped, which is not the case with sand or sawdust, and, so far as I can see, it possesses all the desirable features of either. Cost in some localities might be a possible objection; but the sand would be as expensive as the lumber here, and I doubt not in some places it would be even more so.

We have had a very poor season in this part of the State, owing to hot winds and little or no rain. During the last week, however, we have had some good rains, and bees are doing a thriving business to-day. We can hardly hope for much surplus, though. H. C. ALLEN.

Rising City, Neb., Aug. 22.

Friend A., the very first hive-stands I ever used were made very much as you describe. I procured nice clean dry-goods boxes, or cases, from the stores, and sawed them in two in the middle, so that each made two. The objection to having them so large is not only the expense, but, more than all, that you jar the hives whenever you step on this hive-stand. And where they are so large, you are sure to put your feet on them, more or less, in managing your bees and going around your hives. Another thing, these large bases get out of shape in the course of time, especially when the hives get very heavy with honey. I finally decided that I wanted the alighting-board just as large as the bottom of the hive, and no larger; and then I began to use the cover of the Simplicity hive for a bottom-board, enlarging and contracting the entrance by pushing it forward on this same cover.

HONEY CANDYING BEFORE CAPPING, ETC.

The spring crop was a total failure. June and July were good. We never did get much honey here through the summer months before this year. From the middle of June to the first week in August, our bees never did better—especially the Italians and hybrids. Those that were not bothered for increase stored from 35 to 50 lbs. of surplus. I think they gathered a good part of it from cotton-bloom. Lots of the honey would make sugar before it was capped over. I never saw the like before. I should like to ask, 1. What made it sugar, and where did it come from?

2. Will a hive that has ten frames in it, and half of them solidly filled with honey, and the other half of them $\frac{3}{4}$ honey and $\frac{1}{4}$ brood, winter well in this climate or not? I never had them so nearly fill their brood-chamber before.

3. Does the fertilization of a queen affect her drone progeny or not? I have a book treating on bee culture that claims that it does. I have been watching this very closely for some time. I breed all my queens from an Italian queen that I think is pure. I notice that the drones from the queens that produce hybrid workers are not as uniformly marked as those of ones that were purely mated.

Decatur, Miss., Aug. 28. J. R. CLEVELAND.

1. Certain kinds of nectar will candy very soon after it is gathered, and we believe this has been before reported of the cotton honey. Will some of our Southern contributors please enlighten us? 2. Yes, we should say a colony under the conditions named ought to be in good condition to winter. 3. The fertilization of a queen does not affect her male progeny—at

least, the evidence so far is to this effect. Drones from the same queen will sometimes vary greatly in color. The drones from our imported Italian queens are sometimes almost black, while others from the same queen have one or two yellow bands. But we have always found that the drones from imported mothers, whether light or dark, produce three-banded workers if the queens are pure.

THE SEX OF THE EGG DETERMINED BY THE QUEEN'S GUARD.

In reading Dr. Miller's article in GLEANINGS, Aug. 1, a point overlooked by him and all others I have read, came to my mind. The queen's guard is always with her; and when she lays an egg in worker-cells one of the workers goes into the cell and fixes it, taking more time in "fixing" than the queen does in laying the egg. Now, what I want to know is, Does that part of the ceremony have any thing to do with determining the sex? I have noticed this for a period of six years or more, and am now of the opinion that it must have something to do with the sex of the bee. Have you ever noticed this act, on the part of the workers? If you watch the queen when laying you can not fail to see it. The long drouth has been hard on bees in this part of the country. Every thing is dried up, and there is no honey to gather.

Ezbon, Kan., Aug. 16.

DAVID ROSS.

Friend R., I have noticed exactly what you describe; and I have often wondered, also, why this bee that crawls into the cell after the egg is laid should stay such a length of time. With our observatory hive we used to get impatient because these bees prevented us from getting a glimpse of a new-laid egg. You may be right about it; but how in the world are we going to prove it, or determine what the bee does while it has been so long in that dark cell? A cell made of very thin glass might enable us to see what the bee seems to be doing with the egg.

DEATH OF JUDGE ANDREWS.

Our dear friend and brother, Judge W. H. Andrews, of McKinney, Texas, died August 6, 1890, of paralysis. One among the best lights in bee culture that we had in the South has gone out.

W. R. GRAHAM.

Greenville, Tex., Sept. 19, 1890.

You are right, friend G. Judge Andrews has been one of the lights in bee culture, especially in the South. We remember his quiet, kindly ways at the various conventions he has taken the pains to attend; and, by the way, is it not sad that we have not had the pleasure of meeting as many of the great bee-men of the South as we did a few years ago? As the older ones pass away, and the boys take up the responsibilities, let us be careful that these pleasant old-time relations and hand-shakings between friends not only north and south, but east and west, be not passed over nor forgotten.

SUPERSEDEE AFTER THE YOUNG QUEEN STARTS TO LAYING.

You ask if it is the rule that the old queen is allowed in the hive until the young one gets to laying. I think it is, for I have had half a dozen or more old queens superseded this spring, and in every case I found the young one laying

for a week or more before the old one was *deposed*. This I know to be fact, for I have seen both at the same time, sometimes both on the same comb at work laying, not seeming to care for one another.

ARTHUR F. BROWN.

Huntington, Fla., Aug. 8.

DO WINGS OF CLIPPED QUEENS EVER GROW OUT AGAIN?

An old acquaintance who has kept bees for years is under the impression that queens' wings that have been clipped will grow out again, and become perfect; and I have been puzzled more than once to find queens with perfect wings where I was sure I had clipped them. On searching the combs I failed to find the cells where young queens were hatched. I am satisfied, from considerable experience, that, when the queen's wings are clipped quite close to the body, they don't grow out again; but when the tips only are cut off, I'm not sure about it. Can you clear the matter up?

ARCH. DUNCAN.

Wyoming, Ont., Sept. 11.

Friend D., we think you are mistaken; nevertheless, it may be well to watch carefully and see whether queens with the ends of their wings clipped, or, say, with the thin gauze-like part cut off, ever do have it grow again. I have clipped queens' wings in almost all sorts of ways, and I never noticed any change afterward.

SUCCESSFUL WITH DOOLITTLE'S PLAN OF REARING QUEENS.

I have been very successful in queen-rearing the past season with Doolittle's plan, with the exception of one batch of 30 cells, which doubtless got chilled. The bees have commenced to drive out the greatly abused drones. My bees are in the best possible condition—plenty of stores, and gathering sufficient honey for brood-rearing.

BEE-ESCAPES A SUCCESS.

The wire cone bee-escape has worked nicely excepting where the bees were quite young. Such bees are seldom in a hurry to leave their loafing-place.

THE THICK OR HEAVY TOP-BAR FRAMES

have the preference in my apiary—no brace-combs nor sagging to contend with.

Reinersville, O., Aug. 22. J. A. GOLDEN.

POLLEN ON THE BACKS OF BEES.

Inclosed find several bees with yellow spots on their backs between their wings. This appears to be a sort of scab, or hard substance. Several of my colonies show these spots more or less. The bees appear as lively as any in the colony. Is this a disease, or what is it? If a disease, what will cure it? I saw some correspondence a while ago in GLEANINGS inquiring whether bees lose their stings when they sting each other. I saw a case of this kind a few days ago. An Italian was trying to get into a nucleus of black bees. One of the blacks clinched him, and they went spinning around, top fashion, and soon they were trying to pull apart. The Italian had stung the black bee in the abdomen; and in getting apart, the Italian lost his sting, leaving it in the black bee.

SUBSCRIBER.

West Troy, N. Y., Sept. 9.

Surmising that the yellow spots, or lumps, might be pollen, we forwarded the letter to Prof. Cook, who replies:

The spots on the backs of the bees in question are simply masses of pollen. I have often seen just such curious plasters. At this season our

bees are often plastered up with the white pollen of the snap-dragon. The yellow pollen grains on these bees are spherical. I do not know what the kind of pollen is. It does no harm to the bees. They will be cleaned up after nightfall, and the pollen saved for bee-bread.

Agricultural College, Mich.

A. J. COOK.

BLACK WEEVIL IN THE WHEAT, AND HOW TO DESTROY STINGLESS BEES, ETC.

What is the best way to keep the black weevils out of wheat? We are pestered very much with them. Is there any preventive for it?

I will tell you how the \$3.00 queen I bought of you the first of August, 1889, has done. I have had three swarms and two extra queens from 1 lb. of bees and queen in a little over one year. How does that do for a beginner? I haven't taken any honey this year, as there hasn't been any thing for bees to work on here since the first of April. It is all the bees could do to find enough to live on. I love to read GLEANINGS, and am always anxious to have it come. Tell us more about those stingless bees you spoke of.

H. N. JOHNSTON.

Mooresville, N. C., Aug. 30.

Thanks for your kind words. The stingless bees have all "petered out." The cold nights, or something else due to this climate, does not seem to agree with them. In regard to the weevils, we forwarded the item to Prof. Cook, who replies:

The only way I know of to keep weevil out of wheat is to put the wheat in tight, *very* tight, boxes. This is quite impracticable, and so we must be able to kill them when they are once in. By the use of bi-sulphide of carbon, as described in my late Bulletin, this can be cheaply and effectively, and, with due caution, safely done. This can be got at wholesale of Edward Taylor, Cleveland, O. As this will not injure any thing about the mill, and will kill all insects, it is the specific.

A. J. COOK.

Agricultural College, Mich.

PROFANITY AMONG RAILROAD MEN.

You seem to think railroad men are more given to profane language than any other class of people. I do not think so. Very few of the railroad men with whom I come in contact (and I have been one for fifteen years) use profane language. I never swore an oath in my life, and have a brother in the railroad business who does not swear. Neither is a professing Christian, or, at least, we belong to no church. I think I would report any railroad man should I hear him use as profane language as I have heard doctors, lawyers, and drummers use. It is something very disagreeable to me, therefore I notice it probably more than most people would. Why do you address that request to railroad men?

W. H. BUTLER.

Clifford, Ind., Sept. 13.

Friend B., I am very glad indeed to get your report. I addressed my request to railroad men, because in our State, and, in fact, almost everywhere else where I have traveled, there was more swearing among the railroaders than among any other class; perhaps I should say, rather, among the men who handle freight, the men who construct our railways, and the cheaper help employed all along the line. Perhaps it is more true that men are more given to swearing who do heavy work that does not require very much skill, and consequently does not afford very much pay. And while I am writing,

the idea occurs to me that their profanity may be one reason why their pay is small. It certainly dulls the intellect and blunts the moral perceptions to be constantly in the habit of taking God's name in vain.

WHO IS MOST TO BLAME?

Friend Root:—I love to read your home talks. You will never find out in *this* world the amount of good you do. I once spoke to a bright young man about drinking so hard. I said, "You ought to quit for your mother's sake, if for nothing else. She is a leader in temperance work, and president of the W. C. T. U." He replied, "Yes, I know it. But," said he, "if she would stay at home and mend my clothes, and see to my meals and other matters, I think she would be doing a better work." Is she working, do you think, for stars in her crown in this world or that which is to come?

Evansville, Ind., July 21. A HOME MAN.

My good friend, I thank you sincerely for the very high compliment which you pay me; but I fear you are getting on dangerous ground when you criticise so severely one of the W. C. T. U. workers. I have heard young men reply just about the way that one did, and I know mothers sometimes make mistakes in the way you have indicated; but I do think the young man has given us a glimpse of a very, very bad heart. When a youth can publicly and unblushingly shift the blame from his own shoulders off on to his mother, he has got pretty far down on his way to hopeless ruin. I know that many of our prominent temperance women—at least those who have worked hard for great temperance reforms—have been in a like way criticised; but I think that we who perhaps stand off at one side should be very careful about finding fault. It is an exceedingly easy matter to find flaws in the character of every good man and woman. Let me give you a little glimpse of the other side of the question. It is bad for a *father* to be away from his family. Now, in view of this, suppose all *good* men should stay at home, and give, as a reason, that their first duty was to attend to the bringing-up of their children. Where would our nation soon be if this were fully carried out? There are many mothers in my employ; and when they come here to their daily work, their children can not well be brought with them. Some of them, of necessity, are out in the streets, and very likely are much in need at times of a mother's watchful care; but there seems to be no other way in the world for the mother to earn her daily bread.

CAN A PROFESSOR OF RELIGION CONSISTENTLY USE TOBACCO?

At the time of my conversion, at 21 years of age, I both chewed and smoked, and had for about 7 years. At that time, 1871, I had not heard any thing said on the subject; yet after receiving the witness of the Spirit, in about a week, or at most two, I began to be depressed in spirit on account of my tobacco; and I looked around to see what others were doing. I found the class-leaders and other prominent members using it, so I continued to also, but lost the real

sense of God's presence in my soul. I went on in that way, fighting against my convictions, and professing religion for six months, when I attended a camp-meeting, and awoke to the fact that I was backslidden in heart. I gave it up. God returned to my heart, and took the appetite all away, and it has never returned.

Vinland, Kan., Sept. 12. D. H. WELCH.

Friend W., I am exceedingly glad to get this testimony of yours. I have had no experience with tobacco; but I do know that there is very little chance for God's spirit to obtain a lodging-place in the heart while we are conscious of holding fast to something that duty and plain common sense admonish us to give up. No wonder God took away the longing for tobacco. You gave it up for his sake, and you have your reward.

NOTES AND QUERIES.

The honey crop was good this year. Average, 55 lbs. per hive. IRA L. DONALD.
Smyrna, Fla., Sept. 8.

Bees are doing well now, getting plenty of stores for winter at last, but that is nearly all of it; but I am glad for that.

PETER BLUNIER.

Roanoke, Ill., Sept. 18, 1890.

PROSPECTS GOOD FOR FALL HONEY.

Our bees did well in spring; but dry weather came and stopped work in the sections. The prospect for fall honey is pretty good—plenty of goldenrod, and some Spanish needle, and bees are working well.

D. H. WELCH.

Vinland, Kan., Sept. 12.

A UNIQUE WAY TO GET CAKES OF WAX OUT OF PANS.

Tell Dr. Miller that, when he wishes to clean the dripping-pan of his solar wax-extractor, to turn the pan bottom up and pour a little boiling water over it, then with a table-knife loosen the edges of the mass and it drops out all in a cake.

G. B. REPLOGLE.

Centerville, Iowa, Sept. 4.

[Many thanks, friend R. The idea is ingenious, and will work, without doubt.]

GETTING BEES TO TAKE THE HONEY FROM COMBS PLACED IN AN UPPER STORY.

How can I get bees to take honey from combs placed in an upper story, or anywhere else, so the colony that I want to have honey gets it? I have no extractor.

W. R. TATE.

Goodman, Miss., Sept. 8.

[There is no quick way. If combs are placed in an upper story in the fall, with an enameled cloth between, but turned up a little at one end, the bees will, if short, carry the stores below in time, say in a month. But it is not very satisfactory at best.]

HONEY FROM JAPANESE AND NONE FROM THE COMMON BUCKWHEAT.

I sowed a late piece of Japanese buckwheat, which is furnishing a nice flow of honey now. The common buckwheat has ripened, and the bees did not work on it at all. They are working early and late now.

J. W. CHAPIN.

Winfred, S. Dakota, Sept. 1.

[We are exceedingly glad of the above report, because on page 677 of our last issue there was

one just the other way. The truth of the matter is, I presume, that the varieties differ enough so that one may yield honey when the other does not.]

BURDOCK.

You fail to mention burdock as a honey-producer in the A.B.C. I find it very productive, bees working on it all day. CHAS. MATHER.

Cascade, N. Y., Aug. 4, 1890.

[Burdock has been frequently mentioned as a honey-plant. In fact, I have seen almost as many bees working on burdock at one time as I ever saw on some of the much-lauded honey-plants; but it is a fearful weed, and draws heavily on the soil. Who would think of raising burdocks, even if they did give honey by the tons?]

STOLEN BEES.

Last Friday night one of our colonies was stolen. Do you think they will come back again, if they are let out? They have them penned up yet, so I guess they have had no chance yet. They are a few hundred yards off from my house. JOHN HERBSTLER.

Galena, Ill., Aug. 21, 1890.

[To be sure, the bees will come back again, if they have opportunity; but, now, are you not making a mistake? Is it not only a surmise that they are within only a few hundred yards of your house? I should hardly think they could be kept confined nearly a week, as you state it.]

MYSELF AND MY NEIGHBORS.

A righteous man regardeth the life of his beast; but the tender mercies of the wicked are cruel.—Prov. 12: 10.

In my talk about the new railroad, I touched upon the matter of cruelty to the horses but incidentally. I told you that the men who let their passions run away with them, and yield to the impulse to give vent to these passions in oaths and curses, using every sacred word they could bring to mind, are the ones that are abusive and inhuman to their horses. The latter part of our text tells us that even the *tender mercies* of the wicked are cruel. As they are crowding this railroad to its utmost, they have offered large pay for men and teams; and a good many who own only very indifferent teams have been induced to put them to drawing dirt by the stimulus of the \$3.50 a day which they offer. A good many boys are also set to work to drive. Boys do not cost as much as men, so you see there is quite a chance for speculation. I had heard, before they came on to our grounds, of cruelty toward the horses, and I was determined to do what I could do to restrain it, and, as much as possible, in the same line I undertook to restrain the profanity—by the spirit of Christian kindness. Many of the teams, being unused to such work, were exceedingly awkward; and the experienced man—that is, experienced in railroad business—made no allowance for the poor dumb brutes on this account, but cursed and pounded the poor beasts when they were doing the very best they knew how. By the way, did you ever, in your sober moments, think what a cruel and ungentlemanly thing it is to abuse anybody—man, child, or dumb brute, because of inexperience? It was in my mind to include women; but the thought of being cruel to a woman, when she is doing her very level best, came so near to stirring up my feelings that I thought I would not put her in the list. Surely none but an intemperate man

would think of being harsh and cruel to a woman because she did not understand what is wanted. But we are going to talk about horses to-day, and not about women. Most of the teams on the work were too poor in flesh to do their work well and easily. I am very well aware that work-horses may have too much flesh to stand heavy work day after day; but I believe that this extreme is seldom met. The poor horses seem to be willing and anxious to please; in fact, the greater part of them showed more life and energy than I expected horses to show when their ribs and joints are almost protruding through the poor hide that covers the animals. How I *did* long to see what the effect would be to give them all the grain they could consume, especially while they were on the job! Quite a few fell down from exhaustion (or swearing—which was it?) and had to be turned off by the boss as unfit for the work.

One afternoon, toward night, I saw a poor heavy horse panting to such an extent that its eyes fairly stood out in their sockets. As it pulled the scraper to the top of the heap of soft dirt, it swayed one way and another, and trembled as if it were almost ready to fall down in its tracks. Besides this the blood was streaming from one of its legs. It had been hurt in getting through a bridge some days before. A bandage had been put over the wound; but the heavy work had knocked off the bandage and started the wound afresh, and loss of blood, probably, had something to do with the exhaustion of the poor animal. It seems to me, that a man who would work a horse under such circumstances, simply because by doing it he could get \$3.75 a day, ought to be horsewhipped himself. But this would not be the method taught by Christ Jesus. I saw him before I had reached the spot, and asked the boss why he allowed the man to work with such an animal. He said there were certain reasons why he did not like to interfere, but he had been rather hoping somebody who belonged to the Humane Society would come around, and then he would have good authority for ordering the man to take his horse home. Is not this a hint to the workers in the Humane Society? The team came near where we were standing. Said I, "My friend, do you think it right to work a horse under such circumstances?"

"Well, I suppose it is not exactly the thing. But I have no other horse to put in; and unless I use him it throws me and my other horse out of work."

I told him I was a member of the Humane Society, and I thought he had better not work the horse any more, especially while he was in that condition. The boss then very readily indorsed what I had said. Now, friends, he who acts as an officer of the Humane Society needs much skill and judgment, and knowledge of horses. A horse really *unfit* for work, in the hands of an ignorant swearing man, and one with poor judgment, might do very well, and work without very much fatigue, under the guidance of an experienced, competent, kind driver. In all my work in life I am pained almost constantly to see waste labor and waste motions. In this simple matter of drawing dirt, the horses were sometimes driven many weary steps that were entirely useless. After the scraper is emptied, the thoughtless driver frequently goes quite a distance, instead of turning back promptly as soon as his work is accomplished. Awkward, blundering drivers pull the horses away over to one side until they are out of the path, and then, with curses, jerk them back the other way, when the fault was entirely that of the *driver*, the poor horse having been *perfectly* obedient to the pull on the lines. Why, it is enough to make one's blood

boil to see it. And this matter of letting boys who are too small or too young, worry a team until it is tired out; and I have seen horses thus worried and fatigued, when, if let alone, they would have shown much more intelligence than their driver.

If I was disgusted with mankind during these days of experience, I was at the same time taught to reverence and respect the intelligence of these dumb friends of ours. When the cut became quite deep, steep passageways were made through the bank, to enable the horses to get up with their load. As the pile of dirt became higher, these steep roadways became steeper and steeper. The horses that had had no drill on the work could not go up and down them. But these faithful friends soon learned to plant their feet where the road was so steep that they literally slid down, as boys slide down the cellar-door. They soon learned, too, to do their work carefully and easily if they were not annoyed, yanked, jerked, and pounded by a blasphemous driver. Did you ever watch a horse when its driver was swearing at him? See how his naturally bright eyes settle down into a kind of dull, hopeless despondency. His ears, that are usually ever in motion to catch the least word from his master, drop back sullenly as if he had decided that it is of no use to try any more; that the only thing was to plod along as best he could—"bear the toil, endure the pain." Dear friends, do you ask why I stop in quoting these closing lines of my favorite hymn? I stopped because the poor horse, so far as we know, has no such support as we have. The God who made him has never given him, so far as we know, a promise of some wonderful reward in the unknown future, if he is patient and faithful and kind. If this is true, oh how much more does it behoove us to treat him as one of God's creatures, and, out of respect for the great Father above, if nothing more, treat him kindly and lovingly; to recognize him as a great and precious gift from the loving Father above!

Of course, our big Clydesdale team was working near them, moving the rich soil from the surface of the ground. Most of the railroad men stopped, sooner or later, to admire and point out the contrast between such a team and the rest on the job. Our team did their work easily and well. They filled the largest scrapers on the ground, without sweat or fatigue. Somebody started a report—I do not know how—that there was not a man on the grounds who could stall them by setting the scraper down into the hard ground. These horses have seldom if ever been tried to their utmost. They hardly know what it is to undertake to move something and fail. The boss came along one day, and jestingly asked the driver if it were true that nobody could hold them with a scraper. Several were standing around, while the driver quietly remarked that he did not remember that anybody had ever yet stalled them. Now, there was a hard-wood stake a little ahead that needed grubbing up, but nobody had yet got around to it. It was pretty well covered with dirt. The driver knew where it was. As the boss took hold of the scraper and loaded it up, the driver turned the team in the direction of the stake. Just as the boss got ready to show his skill, the driver gave the big team a signal. There was a burst of merriment as the boss picked himself up from over between the horses; and he just happened to remember then that he had urgent business on another part of the grounds. Finally, as the men were crowding upon us with additional teams, old Charlie, who draws the market-wagon, was hitched to a smaller scraper, and set to work. I intended to get along soon, and give the driver directions; but something

called me; and, before I knew it, good faithful old Charlie was panting for breath, and would probably have come pretty near falling down too had not somebody interfered.

Let me explain a little. Old Charlie was purchased some time ago, at an astonishingly low price, for so large and fine-looking an animal. After the purchase, however, we discovered the reason for the low price. He was wind-broken. He will pull an enormous load, and walk faster than any other horse I ever saw, if you keep watch of his wind, and do not let him overtask it. With a careless driver, however, and one who is unused to his infirmity, he will, if pushed, get out of breath and fall down in the road. He has done it several times—not of late years, however, for I will not permit it. At one time in his life, old Charlie was a celebrated walker. He would walk ahead of any horse in the surrounding country; and he is often now so ambitious that, if not constantly watched, he will lose his wind. Over two years ago, during the hot, dusty weather, he gave out, and most of the horsemen said he was used up, and that I had better "trade him off," or take him off and shoot him. I sent for a veterinary surgeon, and he said the horse was just as good as he ever was, if rightly treated. We had been feeding him dry chop feed. The surgeon forbade that, and said we should give the horse corn fodder, little potatoes, or any thing that he seemed to want, instead of dry grain, and he would do his work without trouble, providing we remembered to keep careful watch and not let him go beyond the limit of his wind. To-day you could not buy old Charlie for \$150. With all Charlie's ambition and great strength, he is nervous and impatient at any thing like being yanked and nagged, especially by small boys. If anybody comes around him whom he thinks may be inclined to take delight in worrying him, he bites savagely. I have been told that boys punch him and pinch him for the purpose of seeing him act up. If he gets worried or excited, it increases his infirmity. By the way, friends, isn't that the case with almost anybody? Well, after I explained to the driver Charlie's good points as well as his weak ones, I told him that he must work on all the dirt that was to be drawn a *short distance*—let the big Clydesdale team take the long pulls. In a little time I saw Charlie doing "big work," and doing it easily, and apparently enjoying it. Several remarked, before long, that old wind-broken Charlie would move more dirt than many of the *teams* on the job. I spoke to him approvingly several times as I passed by; and knowing his disposition as I do—his wonderful energy and ambition—it just seemed to me as though I should like the fun of working side by side with old Charlie, every day of my life; and I am sure I could make him happy; and I feel equally sure that old Charlie, with his great energy and faithfulness, would make *me* happy. Dear reader, is it your good fortune to own a horse or to work with one? Make that horse your friend, and I assure you he will do his best to make himself *your* friend. Last night my wife asked me if it did not seem strange that man and wife should get along so nicely together, while each one would get along so uncomfortably without the other. I replied that I did not think it at all strange, because it is a relation of God's own planning; and it seems to me just now that the relation between the horse and his owner is much that same way. Neither would be happy without the other. But when the two work together in a loving and friendly way, it seems to me as if God's blessing rests on both. I do verily believe that we are only carrying out God's plan in the beginning, in these relations with our domestic animals; and whenever we fall in line

with God's plans we may be sure a blessing will follow.

A few days ago a horse was wanted to pull brick, by means of a pulley, to the top of an elevated reservoir. One of the Clydesdales happened to be in the stable. The man who usually handles him was away with the other. The question was asked if it would be safe to set Jack at that work. A wrong move might endanger the lives of the workmen on the scaffold. I told them that Jack would be perfectly safe if a good man would stand by him till he comprehended what was wanted of him. As his surroundings were strange, and his daily companion was absent, he seemed at first a little fidgety; but I carefully explained to him (you need not smile at this) what he was to do; and after he had taken half a dozen trips he stopped promptly when the mason called from the top of the tower to hold on; and in fifteen minutes more, to the merriment of the boys, Jack, after hearing the call, "Hold on!" turned around with his whiffletree and marched back to the point of starting, without any help from any one. The mason now called from the top of the tower, saying that we should put a little bit of white board on the grass, right where Jack was to stop, and that the horse would walk right up to that board, and stop every time. This he did all the rest of the day, without making a single mistake or blunder. It was evident that he kept watch of the movements, for he looked up to the top of the tower occasionally, as if he were taking in the whole plan of proceedings. I would rather have a smart horse for my helper than a dull man. The horse generally has his mind on his work, and knows what is going on, while the man sometimes does not.

Now, there is one point I think I must take up in this paper, or else some of my good friends who know more about horses than I do might call a good deal of my talk all "folderol." It is this: While kindness and gentleness and love are always in order, firmness and decision are also needed almost constantly. A few days ago we wanted the Clydesdales to pull a stick of timber up to the large underground reservoir. There was a roadway down into it, where they draw out the dirt, and the horses evidently took it for granted that the driver meant to drive them down into that fearful hole. *He* knew what he wanted, but *they* didn't. They began to snort and prance, and finally one turned one way and one the other. Lines and traces were getting badly tangled. Three or four men took hold of them, and tried to straighten them out; but what can a man do with a horse of such tremendous weight and strength? Why, a man's strength would be as nothing, and I expected to see a regular smash-up. The driver gathered up his lines, and, with a yell, commanded the horses to straighten out, hitting them a good clip by way of emphasis. His voice, which they knew, was of more weight to them than all the men whom they *did not know*, and they straightened out in their places in a twinkling. They trembled with excitement; but for all that, they obeyed orders. A thousand times, valuable human life might have been saved by prompt energy and decision, by the free use of the whip, or perhaps a club, or any thing that could be got hold of, to let them know who is master; and a man or woman who would complain of cruelty to animals under such circumstances, is simply weak and childish. Of course, the driver should hold his temper, and not a single blow should be struck more than is necessary to enforce obedience; and under no circumstances should they be pounded or whipped after they have been made to obey. Old Charlie draws kindling-wood every afternoon. The new building, how-

ever, has cut off his regular path so that he has to back around in order to load up the kindling. But this could be managed easily if he would go into a narrow alley and back up until his nose nearly touches the new building. His driver said he could not make him do it. I told him he must whip him until he *did* do it. He said whipping did not do any good. By my orders he showed me how he acted. Charlie went almost far enough, then pranced and snorted, and, in spite of the whipping, he backed the wagon the wrong way, and smashed it into some other things where he might have done injury. I looked around until I found just what I wanted. It was a narrow strip of barrel-stave. Charlie saw what I had; but he had evidently made up his mind that he was not going up on that walk, even for *me*. I told him where to go, and led him up. He stopped as before, and I gave him one pretty good whack on his great fat haunches. He went ahead a little further, and then threw up his head and began to back as before. Then I gave him such a slap it made him grunt a little. But he was not quite conquered. The third blow I gave with all my might, and he walked up as meek and obedient as a child. Since then he goes right up in that place without any more foolish actions and display of his notions and stubbornness. Now, a horse, like a child, sometimes enjoys this sort of fun—a conflict with authority. It is rare fun for him to discover that his master has not force and decision enough to make him do what he ought to do; and it is like cows with a broken fence. The more times they jump over, the more and the higher they try to get over after it has been fixed. This question of who is going to boss things is sure to come up sooner or later between the horse and the owner. The owner should be careful about insisting on any thing that endangers the horse's safety. He should also beware of giving command where he is not well prepared to enforce obedience. Horses have better memories than we do. I have sometimes thought, too, that they have a *wonderful* faculty for taking a man's full dimensions. Let a stranger take hold of the lines or attempt to give orders, and they *very soon* decide how much "lord of creation" there is in this new master or new driver. Now, do you suppose a horse thinks *less* of you when he finds that you are not to be trifled with, and are fully competent to rule? Why, bless you, no. It is with a horse as with a child. His *love* for you is in close relationship to his *respect* for you. He loves the hand that *makes him mind*, a hundred times better than the one who lets him have his own way in a feeble, helpless sort of manner.

Now, dear friend, whose eye rests on these pages, if you have any thing to do with horses, please look upon them as one of God's most precious gifts. Do not scrimp them in feed; do not scrimp them in nice pure water. Take pains to carry them the apple peelings and cores—that is, if you can not afford to give them whole apples. If they like potatoes, as Mike and Charlie do—yes, and Billy (he is the one that ate the peck when they were \$1.20 a bushel), give them the small potato-peelings. Sift out the dirt so they will be nice and clean. Give them the sweet corn after the ears are plucked, and all the dainties that they like, that the house affords. Teach the children to love them and care for them; but at the same time, if you would win their respect as well as their love, teach them to be obedient. Be *patient* and *long-suffering* with your horse. He knows when you give way to temper, just as well as any human being knows; and you sink in his estimation the minute you do so. *He* knows when you strike him or scold him for something

that was not his fault; and he is ready and quick to write your name down in that wonderful accurate tablet of his horse memory. You can not apologize to a *horse* as you can to a *man*; and it will take you a long while to wipe out the memory of some undeserved insult. God gave you sense and reason and *dominion*; but he gave the noble horse, too, a kind of sense and judgment and wisdom that oftentimes comes very near the God-given intellect of humanity.

In closing, permit me to print again something that appeared in GLEANINGS for November, 1882.

My friend, are you and your horse good friends? Do you love him, and does he love you? Does he know, whatever comes up, that you are his friend? Do you know, whatever comes up, that he is *your* friend? Have you such a broad charity for him, that, when he makes a mistake, or doesn't understand, you are kind and patient with him, instead of calling him a fool, or saying he doesn't know any thing? Has he such confidence in you, that, when you make a mistake, and once in a great while (?) speak cross, or "holier" at him, he will forgive it and not be stubborn and contrary? When you work together, are your relations of a truly friendly nature? Is the service a loving service on both sides? May be your horse is old; may be he is one of the dull kind; may be he is lame or blind; if so, and you are even a little bit of a Christian, you are all the more bound to bear with him. Don't you think old and broken-down horses can appreciate kindness? The kindest man I ever saw to his horse and cow is Professor Cook. I don't know but the kindest horse and cow I ever saw were Professor Cook's too. I have sometimes wondered whether they, too, with the rest of the Michigan people, know that he is professor of bugs and insects, and feel a little bit proud of their office of helping him along in his work in the Agricultural College.

If your horse is poor, I don't know how we can make any excuse for you; in fact, I don't know how God can excuse you. Starving the ground may not be a cruelty; but starving a horse, and then asking him to work hard every day, is one of the worst things I know of. If I wanted to pick out a Christian, I should look for somebody riding behind a horse that was fat, sleek, and happy. I don't so much care if he does ride in an old rickety buggy, for buggies don't get tired (only at the blacksmith shop) and *cross*; but when you are weak, faint, and hungry, how would you like to draw some stingy old curmudgeon through the mud? Our Jack is about 18 years old; but I have lately made the discovery, that, when he is fed regularly and well, and is watered at least three times a day, he marches out of his stable, with head up, as much as to say, "Hurrah, boys! come on with the buckwheat or rye you want soon; and if you have any hard work to do, just mind your whiffletrees are strong."

You see, Jack has all his life been celebrated for breaking whiffletrees; and when a load doesn't come, and he is urged the second or third time, he will lie down to work with an air that says, "All right, if you want something to come," and something *does* come too. Sometimes it is the whiffletree, and sometimes it is the whole forward end of the wagon; but to do this, he must have good food, and plenty of it. Now, mind what I tell you: Neglect of or unkindness to your horse will surely stand in the way of your peace with God, and your highest happiness here on earth.

Poor faithful old Jack! After giving a life of almost twenty years of faithful service to our family, letting each new baby learn to drive by holding his lines, and learn to ride by trying to sit astride of his great broad back; after carrying the whole family, singly or collectively; after pulling boxes and packages through the mud, for our whole factory, almost, and never flinching, poor faithful old Jack lost his life by the burning of our warehouse, March 7, 1886. He was the especial property of my wife, having been raised by her father; and now the only memento of this faithful old servant is a blackened horseshoe. May God help us to remember these household treasures while they are with us!

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

That art on which a thousand millions of men are dependent for their sustenance, and two hundred millions of men expend their daily toil, must be the most important of all—the parent and precursor of all other arts. In every country, then, and at every period, the investigation of the principles on which the rational practice of this art is founded ought to have commanded the principal attention of the greatest minds.

JAMES F. W. JOHNSTON.

STRAWBERRY-RUNNERS, AND HOW TO GET THE LITTLE PLANTS EQUALLY SPACED AT THE LEAST EXPENSE.

Terry, in his book, recommends letting the runners go—that is, with some care and directing, and finally, late in the fall, to cut out with a garden trowel, or similar implement, all surplus plants so that no two plants stand nearer than six inches apart. Mr. Pierce, in the *Ohio Farmer*, suggests that it is much cheaper to accomplish the same thing by spacing the runners, putting the little plant where it ought to be, and holding it down with a piece of dirt. We have for years practiced both ways, and we have also practiced letting the runners and plants follow their own fashion. Now, I am quite sure that very much may be gained in quantity and in size of fruit by judicious spacing; but at present I am unable to determine which is the cheaper—probably a combination of the two ways; and this is really the plan which Terry recommends. We have been in the habit of having boys take care of our strawberries to a large extent; but our Gandies and Bubachs, put out in July, have now set so many plants that it is getting to be a complicated matter for a boy. First, I tell them the runners must be swung around so as to be out of the way of the cultivator, at the same time spacing them so that none shall be nearer than 6 inches. Second, sometimes the runners cover the ground thickly on one side, and few or none on the other; therefore a part of them must be swung around when the case demands it. Third, if one plant sends out a great number of runners, and its neighbor on the other side but few, then the greater part of them should be swung around so as to fill up the space around the feeble plant. You can teach a boy to remember *one* thing pretty well; but when he has got to keep in mind, all at once, *three* things—namely, the path of the cultivator, keeping them 6 inches apart, and filling the vacant spaces, it is too much for him. A man or a pretty good-sized boy, and one who can keep his mind constantly on his work, is demanded for it. Oftentimes the plant has taken root before we get around; and if it has gone out at right angles, right in the path of the cultivator, it had better be moved. Now, pulling them up is not a good way. After a little plant has put out white roots, and got a good hold on the soil, it seems to be discouraged by jerking it out; and unless rain follows, the roots will not take hold of the new place. It is just as quick, and a good deal neater, to remove a little ball of dirt with the plant, by means of a common garden trowel. If, after all, the plants start too thick, and some of them *must* be taken out, do not do it by pulling them out nor by digging them out. Friend Terry has the credit of originating, if I am correct, a much quicker and simpler way. Slice off the top of the plant with a sharp garden trowel, just below the crown. If you cut too low you make unsightly holes in your strawberry-rows. If you do not cut *low* enough, the plant will start to grow again. With those who have only a few plants in the garden, there is no trouble about spacing them where you want them, as fast as they push out; but for field culture, getting the plants so as to

make a good stand over the ground and not be crowded is one of the main points; and it is something that costs quite a little labor, too, to have it done well. I mention these things now, because it is time to get right at it. With a favorable fall, we expect our plants to put out runners and make new plants for fully a month yet; and we also expect these new plants made in October to bear fruit next year. If they keep on pushing out and taking root clear into November, I am going to encourage them in it all I can. Our plants put out *in August*, with the transplanting-tubes, are also making some very handsome new plants.

EDITORIAL.

He paweth in the valley, and rejoiceth in his strength. He goeth on to meet the armed men.—Job 39:21.

We have at this date 10,112 subscribers.

The two car loads of honey mentioned on next page have arrived *in excellent order*.

NAMES OF PARTIES THAT CAN FURNISH MOSS, AS MENTIONED ON PAGE 680, LAST ISSUE.

UP to the present date, only three names have been sent in; namely, C. H. Welch, Krumroy, O.; Christian Weckesser, Marshallville, O.; C. Gere, East Springfield, Pa.

THE BENTON CAGE.

As the essential features of the cage we have been using for the past season were borrowed from the above, we have decided to credit friend Benton \$50.00 for what the benefit his experiments have been to us.

INTERNATIONAL AMERICAN BEE-ASSOCIATION.

This will meet in Keokuk, Iowa, Oct. 29, 30, and 31, as will be seen from the convention notices, printed on page 711. It has been a rather bad year, and it is possible that some members may not feel able to stand the expense of attending this year. However, we hope there will be a large *local* attendance at any rate. Our friend C. P. Dadant has done some effective work, and his efforts will very likely make the attendance as great as heretofore.

LOOK OUT FOR THE GOLDEN BEE-HIVE.

Of course, our older readers will not need any caution, as it has been shown up again and again. Some of our younger ones have not, however, got thoroughly posted, as is evident from the following:

Can you tell me whether a man by the name of Jas. B. Pickert has any patent on the "Golden" bee-hive? He has sold a great many farm-rights through here for \$10.00. W. HINES.

Mt. Airy, N. C., Sept. 5.

You will remember that it is the Golden bee-hive men who have forged a testimonial from Prof. Cook; that is, they in their circular publish a testimonial from Prof. Cook, and yet he not only never used it, but he never *saw* a Golden bee-hive in his life.

BEE-CONVENTIONS: HONEY AT HOTELS, ETC.

SCARCELY ever have we attended a bee-convention when we found good honey at the ho-

tels, or the hotels where special rates have been made for bee-keepers. By way of suggestion we would recommend that the secretaries of bee-associations see that the hotels which are to accommodate bee-keepers be supplied with first-class honey, both comb and extracted. When bee-men go away from home, they ought to be treated to something as nice as they would have on their own tables. At the International, at Keokuk, in particular, we would suggest that Mr. Dadant, the secretary, procure samples of the finest alfalfa, mesquite, and white-sage honey, that can be obtained, both in the comb and extracted form, the same to be sold to the hotels granting special rates, at a reasonable price. If possible, let there be other samples of honey whose exquisite flavors are unknown to bee-keepers in general. It will be a grand time to have table-talks on the relative merits of the honey while the delicious article is melting with its sweetness in the mouth. If Mr. Dadant can not procure the mesquite and the alfalfa, as well as some of the white mountain sage, we will try to assist him. We make this suggestion public to Mr. Dadant in order that the smaller and affiliated associations may take the hint in time.

HONEY GETTING SCARCE.

It is pretty evident, from quotations in the honey markets, that our product is going to become pretty scarce before another season; and while bee-keepers have suffered from a poor year, perhaps the price may rise to such a point where it can be held, even when honey becomes more plentiful; and thus a poor year may be a blessing in disguise. The fact that there is a big demand for honey, shows that the general public are learning to use it more and more as an article of food—if not the honey itself, in honey-jumbles and other baker's cakes. By the way, there is getting to be

AN ENORMOUS HONEY-JUMBLE TRADE.

Crawford & Taylor, the celebrated bakers of Mansfield, O., are actually using four barrels of off-grade honey daily in the honey-jumble business, and this is only one baking establishment. Not only are they making jumbles of honey, but other delicious cakes as well. Now, then, what bee-keepers have to do is to help these bakers all they can. Inquire for honey-jumbles at your groceries and baker shops. Buy some yourself, and invite your neighbors to try them. This will not only stimulate the honey-jumble business, but it will make a splendid outlet for off grades of honey. Say, Mr. Dadant, why would it not be a good idea to have a variety of honey-jumbles and other cakes made from our product, at the Keokuk hotels? Just include these in your bill of fare with the honey. Oh, yes! be sure to invite reporters to come in and take dinner with us, and then we will suggest the propriety of their using their pens in describing our delicious product.

THE A B C OF STRAWBERRY CULTURE.

AFTER a few sample copies had been sent out, we learned that there is already a book in print entitled, "How to Grow Strawberries." On this account we have changed the title of our book as per above heading.

SETTING STRAWBERRY-PLANTS IN THE FALL.

OUR good friend I. A. Wool, of Elsie, Mich., naturally felt a little bit hurt at friend Yoder's protest in regard to advertising strawberry-plants in August, for next year's fruiting. He writes us, however, that every customer of his is furnished with a little pamphlet, entitled, "The Secret of Success in Growing Small Fruits," and in his pamphlet occurs the following paragraph:

Plants may be set in August and September, and, if well cared for, will produce a fair crop of berries the following season. Some of our nicest berries are grown on this plan; and had we failed to set out a bed in the spring, we should by all means set it at this time, thus securing a supply of berries for the coming season. But as a rule we think it preferable to set in the spring, thus securing a full crop for the following season.

As the matter stands, I do not think there is very much danger of any of the readers of GLEANINGS being misled, either by the advertisement or by what has been written on the subject.

INFORMATION WANTED IN REGARD TO ALFALFA FIELDS.

ONE of our correspondents, Mr. O. R. Coe, of Windham, N. Y., not being able to winter his bees on the mountains, or, rather, to bring them through the spring months, proposes to move his apiary to some alfalfa field in Colorado. He has written to us for information; but as we are unable to give him very much, we have concluded to call upon some of our subscribers better situated to do so. In a letter received, he says:

I desire information as to honey resources, etc., of different places in alfalfa districts of the Southwest, especially along the line of the Arkansas River from Canon City, Colorado, to Garden City, Kansas. From all the information I can get thus far, I think Canon City the place, as there are thousands of acres of alfalfa there (yet more at Rocky Ford and other places), and it is the largest fruit-growing place, so far as I can learn, in the Southwest, and that would give an earlier flow of honey than places where only alfalfa is grown, would it not? I should like to know where the principal alfalfa districts are, and also where it is grown largely, and where fruit and other honey-blossoms abound.

Windham, N. Y., Sept. 15.

A letter directed to Mr. O. R. Coe, as above, will confer a very great favor on a fellow bee-keeper. Mr. Coe says he can winter bees until about March 1, and then he experiences the difficulties of spring dwindling during the long and backward cold weather upon the mountains, and usually loses the greater part of his bees. He proposes to try the experiment of sending a carload to the alfalfa regions, either this fall or very early next spring, hoping there-

by to put them in a locality where bees will not have to contend with the spring troubles, and may at the same time bring him remunerative returns in the way of honey. We shall watch his experiment with interest. Friend Coe will probably enlighten us upon the success or failure of his project.

SPECIAL NOTICES.

WANTED—GLEANINGS FOR MAY 1, 1890.

We will pay 10 cts. each for the above if sent at once. Now, be sure you do not send any other; and do not send any at all unless you can do it right now.

TWO CARLOADS OF HONEY EXPECTED DAILY.

We expect, before this number reaches our readers, to receive a carload of white-sage honey from L. E. Mercer & Son, of Ventura, Cal.; and, judging from the sample we received, we have a treat for those who want a fine article. This honey is whiter than any we ever saw gathered east of the mountain regions of the West. It is almost as white as water, and very thick. This sage honey is also remarkable for the length of time it will remain liquid. It granulates less than any other kind of honey we know of. A small sample mailed free. It is put up in 6-lb. cans, two in a case, and the price of from one to five cans will be 11 cts. per lb.; 3 to 10 cases, 10 cts. per lb.; 10 cases or more, 9 cts. per lb.

COMB HONEY.

We expect, about the same time, a carload of comb honey from W. K. Ball, of Reno, Nev. We have not had a sample of this, but are assured that it is equal to the sample he left with us nearly a year ago. That sample was no whiter than the whitest Eastern honey, but the body of the honey in the comb was so thick that it would hardly run, and the flavor was so mild and pleasant that it was pronounced by all who sampled it to be the best they ever tasted. This honey is gathered almost wholly from alfalfa bloom. When Mr. Ball wrote last, a few days ago, he said the bees were busy on the second crop, rolling in the beautiful honey at a good rate. This comb honey comes in cases holding 24 and 45 lb. sections each, the net weight being about 23 and 45 lbs. each, and there are 32 cases of 2-lb. sections, 32 in a case, weighing about 60 lbs. net. The prices will be as follows:

One to three 48-lb. cases, or one to six 24-lb. cases, 20 cts. per lb.

Four to eight 48-lb., or 7 to 15 24-lb. cases, 19 cts. per lb.

Ten or above 48 lb. cases, 20 or over 24 lb. cases, at 18 cts. per lb. Two-lb. sections at 19 cts. per lb., one or two case lots; 3 to 5 cases, 18 cts. per lb.; 6 or more cases, 17 cts. per lb.

There are also in this car of comb honey, 32 cases of extracted honey, which, judging from a former lot received from Mr. Ball, is extra fine. Price, same as the white sage.

THE DEMAND FOR HONEY.

We never saw any thing equal to the present demand for honey. We get daily upward of a dozen inquiries, and several orders. You will notice in the Honey Column that the commission houses report the market in a better condition than we have seen it for some time. We quote the following from the *American Bee Journal* for Sept. 20:

THE TUNE HAS CHANGED.

The Kansas City honey market report on page 637, says that "the demand for comb honey is larger than the receipts." Yes; and it is likely to be. Quoting it at 16 cents is a farce! Any white comb honey sold at retail for less than 25 cents per pound this year is sacrificed! Bee-keepers should demand that the very meager crop shall bring all it is worth. Chicago quotations are 18 cents, but that is too low. Hold on to the product.

The carload of honey from Arizona is all gone, but the No. 2 grade, which we offer at 1 cent per lb. less than price quoted on sage honey elsewhere. Samples mailed free. We have advanced our quotations, partly because of a better article, and partly because, in the present state of the market, it is worth more. We should be pleased to hear from bee-keepers who have not enough to supply their home demand, and all others in want of honey.

SPECIAL NOTICES.

DISCOUNTS FOR EARLY ORDERS.

We call your attention to our advertisement on the cover of this number, setting forth the advantages of sending your orders early for goods for next season's use. Five per cent allowed on orders during the next two weeks. Remember, this does not apply to honey, honey-packages, and such goods for immediate use or sale.

PERFORATED ZINC ADVANCED AND IMPROVED.

We have for a year past received at intervals of several months notice of a slight advance in sheet zinc. These advances now aggregate so much that we are compelled to advance the list price 20 cts. per sheet, 28x96, and 20 c. on 10 honey-boards Nos. 1, 2, 3, 4, and 13. Revised table of prices will be given in next number. To compensate you for this advance we wish to say that we have just completed a new die for our zinc-perforating machine at an expense of about \$75, and we have spared no pains to make it absolutely perfect. Each of the 70 holes in the die measures exactly $\frac{3}{16}$ of an inch, which is accepted as the correct size by several experts who have made exhaustive tests and experiments. The zinc we have made for two years past has given good satisfaction generally. But a few have reported that some queens will go through it. The new zinc will effectually stop all queens and still allow the workers to pass freely. Dealers in making up their price lists will please take notice of the above advance in the list price.

SELF-SEALING HONEY-JARS.

A few weeks ago our attention was called to a new jar for honey by M. H. Hunt. He had some at the Detroit exposition, and spoke of the way it seemed to please all who saw it. He kindly gave us the name of the manufacturers, and we wrote them at once for sample, and now have 15 bbls. of them in stock. The adjoining cut shows what they are like.

The cover is glass with a rim inside projecting down about $\frac{1}{8}$ of an inch, and between the cover and jar is a rubber band. On the cover is a circular raised place with a notch in the top. The tinned wire bail of No. 13 wire has both ends hooked into holes in the side like the oaken bucket tumbler or like a common wooden pail. Of course, the holes don't go through the glass. This bail is pressed up the oval incline till it snaps into the notch on top, which seals the jar as tight as a Mason fruit-jar. There are two sizes, one holding 10 or 11 oz. of honey, the other about 14 oz. We have them put up 150 in a bbl., either size. Price of large size, \$8.60; of the small size, \$8.00 per bbl. For a smaller quantity the price will be 8 cts. each, or 75 and 70 c. per doz., respectively. No charge for packages. In 5-bbl. lots direct from Pittsburg, Pa., 10 per cent discount from above prices by the bbl.

GLEANINGS FREE FOR THE REST OF 1890 TO NEW SUBSCRIBERS.

Now is the time for getting up clubs of subscribers and extending the influence of GLEANINGS. To make a greater inducement for those not acquainted with it to join our circle of readers, we will give the rest of 1890 free to new subscribers for one year; that is, all new subscriptions received after this date will receive GLEANINGS from the time the subscription is received till Jan., 1892, for \$1.00. We will also include the *American Bee Journal* on the same terms for 75 cts. extra; *The Illustrated Home Journal* for 35 cts. extra, or all three for \$2.15. You never had such an opportunity before of getting three such journals and such a length of time for so small a price.

GLEANINGS; 3 MONTHS' TRIAL TRIP, FOR 15 CTS.

If there are some who will not accept any of the offers above we are still desirous of having them become acquainted with GLEANINGS, and offer to send it 3 months on trial for only 15 cents. The journal will be stopped at the end of this time, unless you send a request to continue. Think of it—

six numbers of GLEANINGS for only 15 cents! Will not many of our readers endeavor to introduce it to other homes on these easy terms?

SENDING GLEANINGS AFTER THE TIME PAID FOR.

We have adopted the plan of many papers, of sending GLEANINGS right along until we receive orders to discontinue; and the great majority of our readers who have expressed their opinion are pleased with this arrangement. It is more convenient to include a dollar with a remittance for an order for goods whenever one is sent in, and it isn't pleasant to have the journal stop when you want it to come along. We therefore continue it till we get orders to discontinue, because this plan pleases the majority. There are some, however, who take exceptions to it; and we want to say to these that we can accommodate them also if they will say, when they send their subscription, that they want it stopped when the time paid for is up. Unless you do this we shall keep it going till we have orders to stop it.

OUR BEAUTIFUL OCTOBER.

Did anybody ever know the like of it? Here it is the 14th day of October, and our garden-stuff is all growing and ripening as in June or July. Not even the lima beans have been injured by frost. We are having the finest cabbage, cauliflower, late Mammoth Sugar corn, cucumbers, lettuce, melons, peas, peppers, pumpkins, radishes, spinach, squashes, and last, but not least, the nicest I know of tomatoes we ever had in the world, and in the greatest abundance right here in the middle of October. And, oh my! how the strawberry plants do grow! Our turnips have not as yet had frost enough to be real sweet, but they are growing beautifully. My friend, have you forgotten to be thankful?

CONVENTION NOTICES.

The next convention of the Turkey Hill Bee-keepers' Association will take place at the Turkey Hill Grange Hall, near Wilderman's Station, three miles southeast of Belleville, Ill., Oct. 30, 1890. All interested are invited. S. BRAEUTIGAM, Pres.

The Missouri State Bee-keepers' Association will meet in convention at Mexico, Mo., Oct. 22 and 23. A good programme, and an instructive and interesting time is expected. All persons interested in bee culture are cordially invited to attend. Good board can be obtained for 75 cts. per day, or 20 cts. per meal. J. W. ROUSE, Sec., Mexico, Mo.

KIND WORDS FOR OUR STRAWBERRY-BOOK.

The small treatise on A B C of Strawberry Culture, by Messrs. T. B. Terry and A. I. Root, is a big book in a small compass. It is primarily a farmers' book, and we would advise every farmer reader of ours to get one and read it.—*The Poultry Monthly*.

A B C of Strawberry Culture is the name of a neat pamphlet of 150 pages, by Messrs. T. B. Terry and A. I. Root. It covers the whole subject in an interesting manner, is nicely illustrated, and is just the work for those beginning to grow delicious strawberries. Price, postpaid, 40 cents. For sale at this office.—*American Bee Journal*.

An excellent little book is T. B. Terry's A B C of Strawberry Culture, just from the press of A. I. Root, Medina, Ohio. It contains 144 pages and a large number of illustrations, and will no doubt be of great value to all beginners in strawberry culture who have the good judgment to buy a copy and use it judiciously. The price is only 40 cents by mail.—*Colorado Farmer*.

I received from you a copy of Terry's book on strawberries, for which I am very much obliged. I have read every word of it carefully. As I raised strawberries in former years by the acre, I will just say it is a splendid book for beginners, and many growers could learn very much from it.

Platteville, Wis., Sept. 27, 1890.

E. FRANCE.

A B C of Strawberry Culture is the title of a little book of 144 pages, written in two parts, the first by T. B. Terry, the well-known agricultural writer, who writes from his farm and what he sees and does, and not as a theorist. The other part is written by A. I. Root, the charming editor of *Gleanings in Bee Cul-*

ture. The book is a plain, practical set of directions for selecting, planting, cultivating, gathering, and marketing the berries. It is a common-sense sort of book, charmingly written, and we can only wish it were in the hands of every farmer in the land.—*The Western Farmer and Stockman*.

We have received from the authors, T. B. Terry and A. I. Root, a little book entitled the A B C of Strawberry Culture. It is really what its title indicates, and gives in plain matter-of-fact language practical suggestions regarding varieties, methods of planting, etc., so that a beginner, by following instructions, need not err in his efforts at growing strawberries.—*The Grange Visitor*.

The A B C of Strawberry Culture is the title of a little book by T. B. Terry, published by A. I. Root, Medina, O. The author has the candor to admit he has made mistakes, and has learned by experience enough about growing strawberries to make his little book of instructions well worth the price.—*Our Rural Homes*.

Black and Hybrid Queens For Sale.

I have 30 nice hybrid and 35 young black queens for sale. Send me 50c and get one of them.
16-17-18d A. D. ELLINGWOOD, Berlin Falls, N. H.

A few mismatched Italian queens, young and prolific. Price 20c each. Order by postal and pay when queens arrive.
C. A. BUNCH, Nye, Ind.

FOR SALE.

100 Colonies of Italian and Hybrid Bees

In two-story Simplicity hives (ten frames) chock full of bees, and plenty of honey for winter, wide frames, T supers; with sections and starters in upper story, complete, for \$2.50 per colony, or offers.

ALBERT ARNOLD.

Newark, Independence Co., Ark.

☞ In responding to this advertisement mention GLEANINGS.

PURE ITALIAN QUEENS.

I have requested my own apiary, with Italian queens from Alley's \$100.00 queen. They are large and very light colored. I have a stock of fine young queens reared from the best of these, that I offer for 75 cts. each, or three for \$2.00. Tested, \$1.50 each. No black bees near here. Can fill orders promptly, and will guarantee safe arrival. Make money orders payable at Flint, Mich.

15trdb ELMER HUTCHINSON,
Rogersville, Genesee Co., Mich.

☞ In responding to this advertisement mention GLEANINGS.

SECTIONS.

\$2.50 to \$3.50 per M. Bee-Hives and Fixtures cheap.

6trdb NOVELTY CO.,
Rock Falls, Illinois.

Please mention this paper

EUREKA FRAME MACHINE.

Something every bee-keeper should have.

Box 106, Somerville, Butler Co., O.
Please mention this paper. 24-23db

"HANDLING BEES." Price 8 Cts.

A chapter from "The Hive and Honey Bee, Revised," treating of taming and handling bees; just the thing for beginners. Circular, with advice to beginners, samples of foundation, etc., free.

5trdb CHAS. DADANT & SON,
Hamilton, Hancock Co., Illinois.

☞ In responding to this advertisement mention GLEANINGS.

Wants or Exchange Department.

WANTED.—I will exchange sewing-machines, new, and fruit-trees, for honey. Address
15-24db E. PETERMAN, Waldo, Wis.

WANTED.—To exchange all kinds of nursery stock, peaches, pears, grapevines, raspberries, strawberries, etc., for foundation, beeswax, empty combs, or offers. Address T. G. ASHMEAD, Williamson, N. Y.

WANTED immediately.—A man to take entire control of 150 colonies of bees. For particulars address
10-20d S. A. SHUCK, Liverpool, Ill.

WANTED.—To exchange new Dibbern tin bee-escapes, brood-frames or hives, for empty combs (either L. or Heddon frame), foundation, or any other supplies. Write
19-20d E. F. QUIGLEY,
Unionville, Putnam Co., Mo.

WANTED.—To exchange Italian bees in L. hives, for two well-trained fox-hounds. Apply at once to J. B. MITCHELL, Hawkinsville, Pulaski Co., Ga.
19-20d

WANTED.—To exchange Ply. Rock fowls, fine stock, for a lot of empty L. combs for extracting, or offers. T. G. ASHMEAD, Williamson, N. Y.
18trdb

WANTED.—To exchange bee-hives for bees, will guarantee satisfactory hive. 18trdb
LOWRY JOHNSON, M'ER, Masontown, Fay. Co., Pa.

WANTED.—To exchange apiary of 150 colonies of bees. Will take any kind of farm stock, goods or groceries.
ANTHONY OPP, Helena, Ark.

WANTED.—To exchange a 200-egg Excelsior incubator, used one season; cost \$25.00, for photographic outfit, books, or best offers. 19-20-21d
O. S. COMPTON, Glenwood, Cass Co., Mich.

WANTED.—To exchange a fine 2-year old registered Jersey bull, for extracted or comb honey, or offers. 19-20d B. T. BALDWIN, Marion, Ind.

WANTED.—To exchange a 6x9 self-inking press, an excellent outfit; cost me \$80.00; four fonts of type. 19-20d L. L. ESENHOWER, Reading, Pa.

WANTED.—To correspond with parties having potatoes, onions, apples, and honey for sale. Prompt attention given to correspondence. Consignments solicited. Prompt returns made.
EARLE CLICKINGER, 121 So. 4th St., Columbus, O.

WANTED.—To exchange a three-sided 8-inch molder or sticker, for a pony planer, or I will exchange hives or one-piece sections for planer.
GEO. H. KIRKPATRICK, Portland, Ind.

WANTED.—To exchange bees, for a lathe, with scroll-saw attachment, a "Goodell" preferred. Write first, giving description.
O. G. JOSEPHANS, Owosso, Mich.

WANTED.—To exchange full colonies of Italian bees and strawberry-plants, for comb or extracted honey. Make offers to
S. F. REED, N. Dorchester, N. H.

WANTED.—To exchange 5000 Jessie strawberry-plants and maple syrup, for Flobert rifle shotgun, ferrets, fruit-trees, grapevines, or any thing useful.
BEN ZURCHER, Apple Creek, Ohio.

WANTED.—To exchange strong Cuthbert raspberry plants, for apiarian supplies or offers.
CHAS. HOWELL, Hackettstown, N. J.

WANTED.—To sell or exchange a hen (6 hens and 1 cock) of S. L. Wyandottes, Menger's strain, for nice extracted or comb honey. State price of honey.
W. M. BOLTON, McComb, Hancock Co., Ohio.

MY surplus stock of Italian queens at 50c each. They are young, laying, and pure bred.
E. D. ANDREWS, North New Salem, Mass.

HONEY COLUMN.

CITY MARKETS.

NEW YORK.—*Honey.*—Market remains in a very good condition, and we are making quick sales at high prices. Fancy white, 1-lb., 16@18c; fair white, 14@16; 2 lb., white, 14@15; fair, 13@14; buckwheat, 1 lb., 12@13; 2 lb., 10@11. Extracted, white, 7½@8½; buckwheat, dark, 6½@7. *Beeswax.*—Demand is small and prices declining in consequence of the effect of the McKinley bill, which makes beeswax free, whereas there was a duty of 20 per cent on the article formerly. F. G. STROHMAYER & Co.,
Oct. 8. 122 Water St., N. Y.

NEW YORK.—*Honey.*—Comb honey is now arriving more freely, but not enough to supply the demand. The market is firm, and following prices are obtainable: Fancy white, 1 lb., 16½@18; 2 lb., 15@16c; off grades, 1 lb., 14@16; 2 lb., 13@14; buckwheat, 1 lb., 12@13; 2 lb., 11@12. Extracted, white clover or basswood, 8@8½; buckwheat, 6@6½; California, white, 7@7½; amber, 6½@7; Southern, 65@70c per gal.
HILDRTH BROS. & SEGELKEN,
Sept. 27. 28 & 30 W. Broadway, N. Y.

ALBANY.—*Honey.*—We have received up to date, 872 cases of comb, and 73 half-bbls. of extracted honey. On Sept. 29 we sold every case we had in store, except four cases of old honey. Have never been able to do that before so early in the season. Prices are firm, as follows: Fine white clover, 18c; medium grade, 15@16; buckwheat, 11@13. Extracted, 7@9.
CHAS. McCULLOCH & Co.,
Oct. 8. 339 Broadway, Albany, N. Y.

CINCINNATI.—*Honey.*—Demand is good for all kinds of extracted honey, and in all shapes, with a fair supply on the market. There is no comb honey on our market. A good deal could be sold, but no famine is created. Extracted honey brings 5½@8 cts. a lb. on arrival. Prices for comb honey are nominal at 14@16 cts. a lb. in the jobbing way. *Beeswax.*—There is a good demand for beeswax at 24@26 a lb. on arrival for good to choice yellow.
Oct. 8. CHAS. F. MUTH,
Cincinnati, Ohio.

COLUMBUS.—*Honey.*—White clover scarce, selling at 18@20 cts. for choice goods in 1-lb. sections. Prospects never better for selling large quantities. Extracted selling at 10@12 cts. per lb.
Oct. 7. EARLE CLICKENGER,
Columbus, O.

KANSAS CITY.—*Honey.*—We quote white 1-lb. comb at 16@18 cts.; dark, 12@14. Receipts light. We have received several cars of comb and extracted from California. We quote 1-lb. same as native; quote 2-lb. comb, white, 15@16. Extra C. and C., 14@15; extracted, 6@7 cts. *Beeswax*, 25 cts.
CLEMONS, MASON & Co.,
Oct. 10. Kansas City, Mo.

CHICAGO.—*Honey.*—Honey sells quite well, and that which is white and otherwise desirable brings 17@18c; but many lots are off in color, stained or dark; such is slow of sale at about 15c. Extracted, in 60-lb. cans and barrels, 7@8c, according to color, body, and flavor. The offerings are fair of all kinds, with a steady demand. *Beeswax*, 27.
R. A. BURNETT,
Oct. 7. 161 So. Water St., Chicago, Ill.

BOSTON.—*Honey.*—We quote our market on honey strong, 17@18 for white 1-lb. combs; 16@17 for white 2-lb. comb; 7½@8 for extracted. No *Beeswax* on hand.
BLAKE & RIPLEY,
Oct. 9. Boston, Mas.

ST. LOUIS.—*Honey.*—There is no change in the situation. Comb honey continues very scarce, and would command a good price if choice. We quote: Extracted and strained, in bbls., 5½@6; cans, 7½@8½. Comb, choice white clover, 15½@16; dark, 13½@14½. *Beeswax*, prime, 27.
D. G. TUTT GROCER Co.,
Oct. 9. St. Louis, Mo.

DETROIT.—*Honey.*—No white comb honey to be had. Fall or dark is selling at 14@15c. Extracted, 7@8. *Beeswax*, 27@28.
M. H. HUNT,
Bell Branch, Mich., Oct. 9.

MILWAUKEE.—*Honey.*—This market is in good condition for honey. The demand is steady, and good values maintained, while the supply is fair to meet the amount demanded. Will quote choice white 1-lb. sections, 17@18; good, 16@17; dark, or old, 10@12. Extracted, in bbls., white, 8½@9½; in kegs or tin, 9@9½; dark, bbls. or kegs, 6@7. *Beeswax*, 26@30.
A. V. BISHOP,
Oct. 11. Milwaukee, Wis.

FOR SALE.—400 lbs. of fine white-clover honey, in 1-lb. sections, in any amount to suit. Price 16c per lb.
HENRY WILSON,
Box 260, Clinton, Dewitt Co., Ill.

FOR SALE.—1000 lbs. extracted honey, all from basswood, and of excellent quality, in kegs of 50 to 200 lbs. capacity. Price 8c per lb., on board cars at Durand, Wis. Address
FRANK MCNAY, Mauston, Wis.

WANTED.—Extracted honey. Give kind, quality, and price. F. A. SALISBURY & Co., Syracuse, N. Y.

FOR SALE.—1000 lbs. of extracted honey, at 9c, in 60-lb. tin cans. Will deliver at R. R. My honey is very nice white clover, thick and white.
CALVIN LOVETT, Otsego, Allegan Co., Mich.

FOR SALE.—1200 lbs. extracted clover honey, in 60-lb. cans, at 10 cts. here.
R. H. BAILEY, Box 81, Ausable Forks, N. Y.

FOR SALE.—About 1000 lbs. fine clover honey, in two solid iron-bound well-waxed barrels. Price 8c per lb. here.
O. H. TOWNSEND,
Alamo, Kal. Co., Mich.

FOR SALE.—5000 lbs. well-ripened extracted honey, in 60-lb. cans. C. H. STOROCK, Durand, Ill. 18-23db

FOR SALE.—1000 lbs. white alfalfa comb honey, in 12-lb. cases, at 16c per lb.; also 4000 lbs. extracted, very fine, in 75-lb. cans, at 10c per lb.
J. T. CLAPP, Supt. Denver Land Co.,
19-22db Broomfield, Boulder Co., Colo.

WANTED.—One or two thousands pounds of nice comb honey. Write giving amount on hand and price wanted. A. D. ELLINGWOOD, Berlin Falls, N. H. 17tfdb

WANTED.—White comb and extracted honey; state price, package, etc. B. WALKER. 17tfdb
Capac, Mich. or Prairie du Chien, Wis.

FOR SALE.—50,000 lbs. of extra fine sage honey in 60 lb. tin cans. Also two carloads of light amber honey, for sale at 6c per lb., f. o. b.
L. E. MERCER & SONS, Ventura, Ventura Co., Cal. 19tfdb

FOR SALE.—25,000 lbs. of the very finest honey, in scant 1-lb. sections; put up in white basswood cases, holding 12 sections. A very fancy lot. The price is 20c per lb. on board cars here. Who wants the lot?
Address L. W. BALDWIN & SON, Independence, Mo. 19tfdb

FOR SALE.—50 one-gal. tin cans of white clover extracted honey; very fine and white, beginning to granulate some. I want 10 cts. per lb. here
G. L. JONES, Grand Ridge, LaSalle Co., Ill.

NEW FACTORY.

We will soon be in our new factory, which will be the largest and most complete in the world. We shall make the best of goods at lowest prices. We are ready for contracts for next season's supplies. Write us.

SYRIAN BEES.

AN UNFAVORABLE OPINION OF THEM.

A correspondent writes that he is thinking of going into bee-keeping, and says: "I am thinking of starting with the Syrian bees. What do you think of them as honey-gatherers? A bee-keeping friend tells me that they are very prolific, and says he values prolificness in a queen above all other qualities. Is this right?"

Well, to a certain extent, yes; to a certain extent, no. A queen should be prolific at the right time; and if she is thus, it is of great value; if prolific at times when her brood comes on the stage of action when there is no honey to gather, her prolificness counts for naught. If your friend had modified his statement so as to make it read that he valued the prolificness of a queen above all other qualities when it could be so regulated that such prolificness would be of the greatest value to the bee-keeper, I would hold up both hands for it; but if his writing thus is to be interpreted to mean that he regards the prolificness of a queen at all times of the year above all other qualities, I must say that I think he is making a mistake. Here, where we have but about six weeks during the whole season in which the bees make any gain in honey, what we want is a queen that can be coaxed to fill the hive to overflowing with brood during a few weeks previous to this honey-harvest, and lay just as few eggs at all other times as is consistent with accomplishing the above object. If your friend had a piece of work which he must accomplish at a certain time, if he were to receive any profit therefrom he would hire his help before the time expired or not at all. If he wished help at a certain time and they did not come until it was too late, surely he would not keep and board them six or eight months because it was not convenient for them to come sooner. Oh,

no! he would tell them that he did not want them, for it was too late. So I say, that, when bees come to the stage of action in any great abundance *after* the honey-harvest is past, it is a damage to the apiarist rather than an advantage. Why I prefer the Italian bees to all others is for the reason that they are more susceptible of being handled so as to get the hive overflowing with bees at just the right time than are the bees of any other race. Also, as soon as the honey-harvest arrives the queen will cease her prolificness, and thus we do not have a lot of "hungry hands" to board when they are of no use to the apiarist. To show that I am not alone in this, I will quote the following from one of our largest honey-producers:

"I get very much the best results from my purest and most yellow Italians. The Italians seem to be very much more disposed to partially stop brood-rearing, and bend all their energies to honey-gathering, whenever there is a heavy flow of nectar, than any other kind of bees which I have tried, and this is a very great advantage."

Now to the question about Syrian bees. That they can not be managed so as to fill the above requirements in this locality, is why I am averse to them, and I think that any one is making a mistake in selecting them as the bees with which to start an apiary. With me they would not start a large amount of brood at any other time save in a heavy flow of honey, and this I think is one of the worst faults that any race of bees can possess; for an extra amount of brood during the honey-yield always means a multitude of mouths to feed after the honey-harvest is past. When I tried the Syrian bees it was with the only hope that they would prove better than the bees which I already had; but when I found out that I could not coax the queens of this race to lay eggs rapidly except in the honey-harvest, I saw that it would be impossible for them to give a large yield of honey.

After doing my very best with them the second year, thinking that I might not have fully understood them at first, I was obliged to record only 50 lbs. of honey from the six colonies which I had, while I had to feed them a large amount to get them prepared for winter, taking combs of sealed honey from the Italian colonies to feed them with, while the same number of Italians gave over 500 lbs. of surplus during the same time and with the same management. With me the Syrian bees would increase but little till the honey-harvest arrived, when they would crowd every available cell with brood, which brood would use up nearly all the honey the few workers reared before could gather while the honey-harvest lasted. On the contrary, when the honey-harvest opened, the Italians would have a hive overflowing with bees, and every comb filled with brood; and this brood would gradually decrease till at the end of the harvest I had lots of honey and few mouths to feed. Here is an item which many bee-keepers seem to overlook in following their profession. Bees are of value only when they come in time to take advantage of the honey-flow; and whether through the race of bees or the carelessness of the apiarist we fail in this point, little profit, or none at all, is sure to be the result.

The same fault that I have spoken of in the above exists to a considerable extent in the Carniolan bees, or, at least, has done so in those I have had. While they can be brought up to rapid brood-rearing before the honey-harvest is upon us, which is different from the Syrians, yet they are determined to breed all through the honey-harvest, and to a large extent after it is past, so that, as a rule, unless they are looked after, many colonies are apt to be short of stores, to go into winter with, while the large amount of brood reared during the honey-harvest takes away quite a quantity of what we should receive as surplus. G. M. DOOLITTLE.

Borodino, N. Y., Oct. 4.

Friend D., there is another objection to the Syrians and Holy-Lands. I feel quite certain that the same quantities of bees of these races will not, as a rule, gather as much honey as the same number of Italians.

A REVERSIBLE EXTRACTOR.

MCINTYRE'S PROPOSED MACHINE PUT TO ACTUAL TEST; AN INTERESTING EXPERIMENT.

I wish to say that I have been very much interested in what Mr. J. F. McIntyre has had to say about reversible extractors (see page 626). His article, published in the Nov. 1st GLEANINGS, 1889, was full of suggestions, and of great interest to us who use the extractor a great deal.

Last spring I made up my mind that I would make a reversible machine; and as I went about my work, for days I thought of little else. My line of thought finally took almost exactly the same course traced in Mr. McIntyre's article that was published on page 626. I made a wooden model, and experimented with that until it was time to begin extracting, when I sent to A. I. Root for a large can with a suitable gearing, and had a tinner make the baskets and inside frame. I made a two-frame machine, which takes a can 24 inches in diameter. The baskets are hung as illustrated in Mr. McIntyre's article, and are simply connected so that, when one is reversed, the other goes with it. A small catch holds the baskets when reversed, as in Fig. 2 (see Mr. McIntyre's article). When in the first position, as in Fig. 1, the heavy side of the basket rests against a projection from the cross-bar that holds the

basket up. It is almost automatic, and is reversed by stopping and turning the other way.

This extractor can certainly be reversed without stopping, but I have not been able to get a frame or baskets made stout enough to stand the strain. Mine accidentally reversed a couple of times while in motion, and I thought it would tear every thing to pieces. I do not believe it is possible to make the frame and baskets stout enough to reverse while going at full speed, without making the machine too expensive; and even if the machine would stand the strain, I am afraid the combs of honey would not, especially the tender new ones in hot weather.

I extracted about 3500 lbs. with my two-frame reversible this year, and I am very much pleased with it. I can do the work at least three times as fast as I can with a non-reversible extractor, and just as easily.

One advantage of this machine is, that the baskets are hung and revolve quite close to the center of the can; in fact, in my two-frame machine the baskets, when reversed are a little nearer the center of the can than they are in the Novice. In a four-frame machine they would have to be further out from the center, in order to give more room for the baskets to revolve in reversing, so as not to interfere with one another.

The baskets seem to revolve with a momentum like a fly-wheel—at least, more so than any I ever used before. There is nothing to catch the wind, besides the baskets and the flat cross-bars.

AN IMPROVEMENT IN THE FOLDING TENT.

I have been compelled to use the bee-tent almost constantly this summer when handling the bees, though there were a few days during basswood bloom when I did not use it. Each season I renew the netting on my tents. With the best of care they will get torn, and once in a while the wind plays havoc with them. This year I used light muslin half way up from the bottom all around, and mosquito-bar only in the top part of the tent. I also sew a piece of light burlap, one foot wide, all around the bottom. If the ground is uneven it hangs down and prevents any bees from getting under. The muslin is an advantage in two ways: It is not so apt to catch on bushes, hives, etc., and get torn; and in the second place (and it is really the more important), the bees can not see what you are doing so well from the outside; and when you set a comb down on the ground the robbers can not see it at all. You who have used the tent much will appreciate this point. I have taken great comfort with mine while preparing my bees for winter during September, when the bees had nothing to do but to watch me.

WINTER PACKING

above the frames in chaff hives, and also in single-walled hives, to be successful, should not be above six inches deep, of chaff or leaves lightly pressed down, and the hive must be provided with holes in the upper part to give ventilation. If sufficient ventilation is not provided for, the packing will gather dampness. If too much packing is used, or it is pressed in too solid, it will get wet. It is also essential that the hive-roof be perfectly water-tight. Some porous material, such as burlap, should be put next to the frames. If these conditions are complied with, the packing, bees, and combs will stay perfectly dry, and there will be no need ever to open out the hive to the sun, or to dry the packing, as I have seen recommended.

The above is the result of several seasons' experience, not with one only, but with dozens of hives. Our bees that were packed in chaff

hives came through last winter in better shape, and did better this summer, than those that were wintered in the cellar. J. F. MOORE.
Rockaway, O., Oct. 1.

We are very glad, friend M., to get your testimony. We do not usually like to publish and illustrate any thing based entirely on theory; but McIntyre's reversible extractor is so unique in its plan that we were constrained to present it to our readers, first, that we might get some of our mechanical geniuses to test it; and, second, that we might ascertain whether the thing has ever been actually tried, and here you have tried it. In my recent visit among bee-keepers I found there was a very strong demand among the extractor men for an automatic reversing machine; and while the one you outline (McIntyre's) may be no better than the Stanley, in actual practice, theoretically it seems as if it were considerable of an improvement by dispensing with the chains and the flopping of the baskets against each other, which I am assured they will do with the best of management, at times. Extracting-tents, with cloth part way up, and netting the rest of the way, have long been in use. When our tents were all made of wire cloth instead of netting, we used to use cotton cloth part way up, on account of economy, it being so much cheaper than the wire cloth.

REPORT FROM GERMANY.

SOME VALUABLE HINTS FROM OUR GOOD
FRIEND GRAVENHORST.

The report in GLEANINGS, Aug. 15, in regard to the crop of honey in America, induced me to send you a report. We had also a very mild winter, and our bees came through it without any loss, therefore in good condition. As the crop of honey the year before was a very good one, we need not feed our bees in the fall nor in the spring; they had more honey than they wanted. The spring was beautiful in the month of April, and our colonies prospered so that we could expect the swarming season in May. But this month was not as favorable as April, as we had only a few very good days when the bees could fly and gather honey and pollen. Nevertheless, my first swarm issued on the 21st of May. Most of the natural swarms issued on the first days, say from June 1 to 12, and at the same time I made my artificial swarms from every colony that I intended to increase. If one of my stocks casts off a natural swarm at the right time, I am glad of it; and if it does not swarm at the time I want it, then I swarm it artificially. Thus I make the increasing time a short one.

I have two kinds of colonies at the beginning of the season—those I intend to multiply, and such as are determined to gather only honey. The latter I make as strong as possible, to have them early in good working order. Swarming is prevented. If there is honey in the field, such a colony will gather it, and then I need not fear their swarming. If they have only a living from hand to mouth, I must be on the watch to prevent swarming. Before the bees build any queen-cells I take out the most of the brood-combs with capped brood, and insert combs without brood and honey, or only foundation.

To enable you to understand me better, I will say a word about my artificial swarms. I make only two kinds. First, I hunt out the queen of a colony just ready to swarm, and transfer her with some young bees, which I sweep from a few brood-combs of the same colony, into a new hive, furnished only with guide-combs in frames. The new colony is placed on the stand of the old ones, and this is removed to another place. Second, I select a strong colony which has many young bees, and sweep with a brush every bee from the combs and the walls of the hive into a new hive furnished with guide-combs. I take care to do this, not for the queen, as I know I shall get her in the new hive with the other bees. If the bees have gorged themselves full of honey by this operation, as bees always do when swarming, they will stay by their queen. If there is no honey in the hive, then I sprinkle the new swarm with a syrup made of sugar and water. I then place the new swarm on a new place somewhat distant from the old stand. I was the first bee-keeper who made such swarms in Germany. They are made in a few minutes, and many bee-keepers in Germany prefer them to all others. The combs, free from bees, I place in the old hive on the former stand. All the bees that were driven off by sweeping the combs will return to their old hive, and some to the new swarm. As in the old hive every minute will hatch many young bees, it will soon be all right, rear a young queen, and fill all combs that are not occupied by the brood with honey, if there is honey coming in. If such a hive, after having swept the bees from the combs, does not contain enough sealed brood-combs to fill it, then I take from a hive just having swarmed, or one that I have just artificially swarmed, as many brood-combs as are necessary to fill the hive, which will hold 16 frames, and give them, with all adhering bees, to this colony.

Now, only think of it! what a mass of bees will be in such a colony when the first young queen is hatched! There will soon issue a very strong swarm. When this swarm is hanging on a tree, or when I have it in the swarm-catcher, lying in the shade of a bush or tree, then I go to the hive it came from, and pull out every queen-cell. Toward evening I then return the swarm. Such a colony will not swarm afterward, although it will have probably more than one young queen. A few days after, there will be only one queen in the hive. As soon as this is the case, such a colony will work to the utmost capability, if there is honey in the blossoms. As long as I have built up such colonies, I have never had a lack of honey, so that, in the poorest season, I have never had to feed such colonies.

□ From the end of May till the 13th of September we had a hard time for our bees. We have had rain, and nothing but rain. Only a few hours in a week did we have fine sunny weather, and that was the only chance for our bees to do any thing. In the worst time we had, I did not have to feed a swarm. The most of our German bee-keepers were not so lucky as I, as they had more rain, hailstorms, and cold days, or their bees had no pasturage if the weather was favorable. My bees did very well in the month of April; some excellent days in June, July, and August, and so I secured a good honey crop from those colonies I have above described. I worked for extracted honey, as we have in Germany no market for comb honey. Rape, fruit-trees, poplars, gooseberries, acacia, linden, and buckwheat were the honey sources.

At the beginning of August I moved my bees to the heather, some miles distant from here, and there we had only four or five days, from the 15th till the 19th of August, very fine weath-

er. My strongest colonies I call double stocks. They have an average of 20 lbs. of surplus honey, and my other colonies have at least their winter stores. The only fault with the heather honey is, it can not be extracted, as it is too slimy, and adheres to the combs in such a way that the combs in the extractor will sooner break than the honey will fly out.

Some of the German bee-keepers have also had a honey crop, as I have; others only in the spring, from rape, etc.; others only in June and July. Upon the whole, the average yield per colony in Germany is in no way better or as good as in America.

C. J. H. GRAVENHORST.

Wilsnack, Sept. 13, 1890.

Friend G., we are greatly obliged to you for giving us this glimpse of bee culture in your own country. You do not manage things just as we do; but very likely you succeed best on your plan and with your surroundings, and no doubt you would get ahead of us if we were there with you; but if you were here, we are inclined to think you might somewhat modify your plan of working.

COMB-SPACING.

MORE GOOD TESTIMONY FOR 1 $\frac{3}{8}$ INCH.

In transferring I invariably find the foundation of combs laid 1 $\frac{3}{8}$ inches apart. Combs are built on this foundation to the thickness of $\frac{3}{8}$ inch when the first batch of brood is capped. This brings the combs the proper distance apart for brood-rearing, while this part of the comb is used for that purpose; but as the foundation is laid out further down, the queen follows after the workers, laying while the comb is building, it seeming to be handiest to lay in an unfinished cell; but as the workers build about as fast as she can lay eggs—she preferring to lay in such cells—she does not return to the first cell as they hatch empty, to again deposit brood therein. Now, the bees, wishing to lay up a supply of stores to maintain the rising generation, occupy those recently vacated cells at the top of the comb, which, in order to economize space and perhaps heat also, they draw out until the intervening space is in the neighborhood of $\frac{3}{8}$ inch. As the tops of the combs are now drawn too closely together for convenience in breeding, and the cells too deep for the queen to use them as easily as more shallow cells (I have seen eggs not more than two-thirds the distance to the bottom of those deep cells), they are thereafter used exclusively for stores. Then this would be natural spacing, $\frac{3}{8}$ inch for stores and $\frac{1}{2}$ inch for brood.

Some writers hint something about following the dictates of nature in this matter; but I object to such a thing; for, should we follow the dictations of Dame Nature, where would the frame hive be in a few short years? Why, we might yet be relishing a chunk of black, pollen-mixed honey out of a lion's carcass if man in his diversion from the laws of nature, in order to bring the world into subjection, had not given us the frame hive. I believe in getting just as far from nature in this matter as possible, which, in my experience, I find to be a $\frac{3}{8}$ -inch space between $\frac{3}{8}$ combs. This is a compromise between nature and convenience, giving room for breeding, with ample room for winter stores. I for one don't like to handle combs with a great "bay window" at the tops where they are drawn out to receive stores; and, so far as I have seen, this is the case where combs are spaced more than $\frac{3}{8}$ inch. I experimented with

three colonies this season, with spacing less than $\frac{3}{8}$, being somewhere near $\frac{1}{4}$ inch, with the following result:

Where any sink in the comb permitted of $\frac{3}{8}$ -inch space, I found capped brood; at $\frac{1}{4}$ inch, honey partly capped; less than $\frac{1}{4}$ inch, nothing much but pollen and uncapped, but there was very little brood in the brood-nest; but, oh my! July 1 I took off from one hive what should have been 50 lbs. of surplus, when I found that one-third of the combs at the bottom were the nicest kind of thin brood-comb built just as I describe above. One inch may be the thickness of capped brood, but I am confident that $\frac{3}{8}$ inch is an abundance of space. It would be a good thing if this matter were *perfectly understood*, in order that persons starting to make hives would know just how wide to make them.

OLD COMBS AND QUEEN-CELLS.

Did any of you or your readers ever try putting an old black comb in a hive to get eggs for queen-rearing? If not, I would advise you not to, unless it is for an experiment. Such cells will almost always be as black as the comb, with texture so fragile as to become flattened by heat that will have no effect on the common yellow cells. I have seen them "wilt" down flat before the bees had time to cap them. I have also seen them after they were capped become flattened on all sides, making them wedge-shaped. Such cells must necessarily produce deformed queens, as described by friend Doolittle in GLEANINGS of July 15. I lately took an old black comb, full of honey, from a hive where the frames had been spaced too close to admit of capping, and put it in a nucleus where it was capped over with material just as black as the comb. The bees seem to think it useless to use material for cappings or queen-cells in these cases better than the foundation they have to work on.

Carbondale, Kan., Aug. 3. J. H. MARKLEY.

Thanks for your testimony. If you will turn back to page 491 you will find that your conclusions agree almost exactly with those expressed by the writer. A space of $\frac{3}{8}$ between capped brood and $\frac{1}{2}$ between uncapped brood would make just exactly 1 $\frac{3}{8}$ spacing from center to center. See also pages 564, 639, and 673. Verily, the evidence for 1 $\frac{3}{8}$ -inch spacing is accumulating.

E. R.

WHAT SPOILS THE GRAPES?

DR. MILLER SAYS IT IS NOT THE BEES.

Previous to the summer of 1889 the bees each year worked on the grapes, and whole clusters were left nothing but skins and seeds. In every instance the first beginning on each grape was a slotted hole, perhaps an eighth of an inch long, in the form of a dumb-bell; that is, a round puncture at each end and a straight cut connecting the two. Last year and this year none of these slotted holes were seen, and the bees did no damage to the grapes. This year the bees were gathering nothing to speak of when the grapes were ripe; and if a basket of grapes were left standing, the bees would work their way all through it to lick up the juice where a grape happened to be broken; but after a basket had stood all day you would not say that they had been damaged by the bees. It seems, therefore, that the bees did not make the slotted holes; and without this first puncture the grapes remain unhurt. Now, what is it that makes the first attack? As it was lacking this year and last, is it not possible that we

could do something to make it lacking every year, if we knew the cause? Do others find the damage commencing with the slotted hole?

HOW MUCH WAX PER COLONY?

On page 701, friend Root, in speaking of Boardman's wax-extractor, you say: "It can not be that they cost very much, if it will pay a man to have one, who produces only 50 lbs. of wax a year." That sounds as if you thought 50 lbs. per year a small amount. To me it seems a large amount. Extracting, of course, produces more wax; but with comb honey I don't think I have ever averaged as much as two ounces per colony, and your remark raises the question whether there may not have been something wrong in my management. I know that, previous to this year, I have not saved wax as I should; but this year I have had one of Green's solar extractors, and I think nothing has gone to waste. The more I think of it, the more I think I shall lessen rather than increase two ounces per colony. If the good time comes when no brace-combs are built above top-bars, then I hardly see where I shall get any wax, except by melting up old combs or an occasional spoiled section. Will that give one ounce per colony? But I should say that it pays to buy a wax-extractor if you have only 25 lbs. of wax per year. I'm not sure but I should want one for only 10 lbs.

ISN'T THIS A FREE COUNTRY?

Friend A. I., I wish you'd look after Ernest a little. On page 702, under the head of "A Few Stray Bits," he talks just as if Elwood, Hetherington, and others had a right to certain territory, and that no one else had a right to go there, and apologizes at the last for even hinting that any one might think of doing such a thing. Now, I'm sure that Hetherington, with his 3000 colonies, has a better territory than I; and if I want to settle right down beside him, I'd like to know what's to hinder. I'm sure I could learn something from him, and it would be convenient to be so near that I could run in any evening and ask his advice. Please don't let Ernest talk any more about any one's "territory." Why, you see if the notion obtains that there is such a thing as a moral right to a given territory, some fool will get up and ask that laws be passed to make the moral right legal.

OBNOXIOUS SECTIONS.

On page 707 you ask, "Is it not true that some sections that have perhaps been tried one or two seasons became obnoxious to the bees?" I have had a few such, but it was generally where the foundation had been drawn out very little or not at all; and, being left on the hive the latter part of the season, the bees had glazed the entire surface with propolis. It is not because such sections have been used, but because they have *not* been used, that the bees reject them; and they are not fit to be used, even if the bees found no fault with them. We all know that bees prefer an old black comb to a bright new one; but one that has remained unused in the hive through late summer, when bees are in the varnish business, is quite another thing.

WORKERS LAYING IN QUEEN-CELLS.

Referring to Frank W. Lighton's case on page 709, I may say that I have had a number of cases in which I looked to see whether a young queen had yet commenced to lay; and I decided she was lost, by finding an egg in a queen-cell and no other eggs in the hive. Sometimes, at least, laying workers are satisfied to stop for a time, after getting an egg in a queen-cell.

Marengo, Ill., Oct. 4.

C. C. MILLER.

Fifty pounds of wax is worth, say, \$15.00. If this amount of wax should be wasted, if the man did not have a wax-extractor, he had better buy one, to be sure. But I was thinking that 30 or 40 lbs. of it would be saved any way. But even in that case, the saving of 10 lbs. of wax would pay for the extractor, providing it does not cost more than \$3.00. Come to think of it, I guess, doctor, you are right, that it will pay to have a wax-extractor where you produce 50 lbs. of wax in a year.—In regard to obnoxious sections, I do remember that these that the bees will not use are almost always well varnished, and perhaps some propolis, too, thrown in. I have also decided many times that a colony was queenless because I found a single egg in a rudimentary queen-cell. I judged this single egg to be the work of a fertile worker, and I think they often commence by laying one egg—perhaps no more—in the hive. After a few days, however, we are pretty sure to see more such eggs.

AUSTRALIA.

A BAD SEASON FOR BEES: EXCESSIVE RAINS.

It is with much regret that I write to tell you of another bad season. The drouth of 1888 and '89 has been followed by a year of excessive rain. In the last fourteen months we have had 108.76 inches; in fact, we have taken to counting our rainfall by feet lately. The average rainfall for the thirty previous years was 31.45. We have had so very few sunny days in the last three weeks that we have had but one day on which the bees could work the wattle (mimosa), which yields the earliest pollen in great profusion. It is all out in blossom now, but the bees have not been able to touch it yet.

The season opened splendidly, but we took only half a ton of honey in the early part of the year. The rest of the season was so wet that the bees could scarcely make a living, much less store any thing, and so we have had to feed them this winter to keep them alive. For miles around us, in fact, with few exceptions, all over the country, the bees in the bush and those in box hives have all died out. One neighbor had 72 colonies in box hives, and has not one now. Another, a few miles away, had 180. He had lost them before winter set in.

MOTHS AND ANTS.

They say the moths and ants have done it, and are much surprised that ours have escaped; but we know the poor bees were so poverty-stricken and disheartened they let their enemies take possession of their hives.

BROOD-FRAMES: METAL CORNERS NOT SATISFACTORY.

We have been very much interested in the controversy going on in GLEANINGS with regard to the wiring and sagging of frames. We wire ours exactly as you describe the process in the A B C, except that we use a shoe peg instead of a tack, and we have never known a properly wired all-wood frame, with tin upright, to sag. The metal corners do. The weight of the honey twists and bends the tins into all shapes, and we are more troubled with burr-combs on the metal-cornered frames than on any other. We have used the reversible frames only two seasons, and they were both poor ones; so it is

rather early to speak; but we have never had burr-combs built on them yet.

SPECIFIC GRAVITY OF AUSTRALIAN HONEY.

I think our honey must be heavier than yours, for I notice you always allow 12 lbs. to the gallon, while ours weighs from 15 to 16, and, in very dry seasons, as much as 17. A four-gallon kerosene-can weighs, net, from 62 to 66 lbs., never less than 62 lbs., and seldom more than 66. Our average is 64 lbs. of extracted honey to the can. We usually find that our narrow frames hold about 10 lbs., and our section boxes 17 or 18 oz. when well filled. When using broad frames for sections we draw the top and bottom bar together with a piece of ordinary No. 30 wire. This prevents sagging, and most effectually prevents the introduction of propolis. I must say, I prefer the wide frames to supers, as the sections look so much neater and cleaner when taken out.

THE IGNOTUM IN AUSTRALIA.

I must thank you very much for the Ignotum tomato seeds you were so very generous as to send me. I was able to distribute them far and wide. All are unanimous in declaring them to be the most prolific and delicate-tasting of tomatoes. At the beginning of the season we were much disappointed, as they rotted in the center before they had time to ripen; but they soon grew out of that, and the vines bore for months, right into the winter. Some six vines, planted on drained and trenched land, produced bushels of splendid fruit. I don't think one seed failed to germinate. The curator of our state nursery, to whom I sent some, said he had never seen finer seed. He was sure that every one he had planted had grown.

S. A. BRADLEY.

Denham Court Parsonage, N. S. W., Aug. 4.

Friend B., when you speak of 15 or 16 lbs. of honey per gallon, one is almost forced to believe that your pounds are smaller than ours, or else your gallons are larger. I judge it must be the latter, for the kerosene-cans you speak of hold the same number of pounds of honey with us; viz., 60 lbs., or two or three pounds over; but instead of calling them four-gallon, we call them five-gallon cans. Many thanks for your good report of the Ignotum tomato.

NECTAR FROM RED OAK.

PROF. COOK TELLS US ABOUT WORMS, BUMBLE-BEES, SNAKES, INJURIOUS INSECTS, ETC.

I send you by to-day's mail a little box of oak twigs on which the bees are working with great diligence. Their whole business seems to be with the little buds—those I have tied thread around. I watched one bud five minutes, and in that time seven bees visited it. The whole seven seemed to be equally well satisfied with the result of their visits. It may be an old thing to you, but I had never observed it before. Farm Ridge, Ill., Sept. 27. E. B. CAPEN.

We referred the above to Prof. Cook, who replies:

The oak which Mr. Capen finds giving off nectar is probably red oak, *Quercus rubra*. I find in the enlarged buds—which are secreting the nectar, the larva of a gall. It takes the fruit-buds of the oak two years to form acorns. These buds would have fully developed next year, and acorns would have resulted, had they not been unfortunate. A small four-winged fly—smooth, and somewhat wasp-like in form,

pierced the buds and laid an egg in each one. This so irritated the tissue that it grew very rapidly, and a gall, or enlarged growth, resulted. In these galls the larval gall-fly may now be seen. The fact that these galls secrete nectar is not new. I think we have had such reports from Minnesota or Nebraska, and from Arkansas. The cause and purpose of this nectar is not easy to divine. I should very much like more of these galls, and a sample of the honey from the nectar.

It is very interesting to know that each gall-insect produces just the same kind of gall. Why this is so, no one can tell. That all galls of the same insect should be the same size, color, and form, as much so as fruit of the same tree, passes understanding.

It is also interesting, that bees get nectar from so many and such diverse sources; from flower-glands, from extra floral plant-glands; from sap, from plant-lice, bark-lice, from fungi, and from galls. Surely the wind is not only tempered to the shorn lamb, but equal love and care is shown in the feeding of insects and other animals.

THE IMPERIAL MOTH.

Mr. Wm. S. Adams, Guys, Md., asks about an immense larva which feeds upon the apple. This is our largest silk caterpillar. It is *Eacles imperialis*. I did not know it worked on apple. It usually works on sycamore. It has great horn-like tubercles. Mr. Adams says the person who caught it said it stretched out to a foot in length. No doubt this was an unconscious stretch of the truth. The caterpillar might possibly stretch to six inches, but even that is too large for the average. Yet, to see one of these terrible-looking larvæ with its bristling horns, might easily lead to exaggerated statements. Yet this threatening insect is as harmless as a kitten. All its swing and waving of horns is simply for effect. It is well worth while to rear the moth, for it is one of the finest and largest of our American insects. It is a lively, beautiful yellow, dotted with black. It always attracts unusual attention, and causes words of surprise and admiration as I show it to visitors. When I show the larva, people generally say, "Horrid!" They all pronounce against the child, but praise the parent.

BUMBLE-BEES — BOMBUS PRATACOLA.

Mrs. S. C. Brooks, Spring Creek, Pa., sends for name, through GLEANINGS, some very beautiful bumble-bees (*Bombus pratocola*). They are about the size of a drone-bee, and, like all bumble-bees, very hairy. These special ones are yellow, black, and orange; the head, a transverse band on thorax, and the tip of the abdomen, are black, and a central broad band across the abdomen, rich orange brown, while the remainder is a bright yellow, the common color of bumble-bees. No wonder, so much are they with the beautiful yellow flowers. We know we grow to resemble in spirit and temper, if not in looks, those very dear to us, especially if much with them. Why may not the bumble-bees, then, grow like the bloom they visit, and which is bread for them? Mrs. Brooks is quite correct. These do not go into the hives. It would be a sorry undertaking for them to attempt it.

THE BLOW-SNAKE.

Mr. S. C. Corwin, Sara Sota, Fla., very kindly sent me two snakes some time since for moccasins. They proved to be the common blow-snake, or blowing adder—not poisonous at all. We handled them and stroked their heads as freely as though they were young puppies. True, they flatten their heads and necks in an alarming manner, which so compresses their

trachea, or windpipe, that they fairly gasp; but they can only frighten. They are utterly powerless to do harm. But friend Corwin was no man to give up, and we have now received a genuine moccasin—upland (not water) moccasin—from him. Though not very long it is prodigious in size, as large as my arm, and as vicious as big. His great fangs would fairly fly out as he would strike at us. As this is our first moccasin, we prize him. I now have fine specimens of all our venomous snakes. I tell you, friend Root, I am going to give the readers of GLEANINGS, when I have time, a snake-story that will raise their hats. I have the data. Just think! we have had live massasaugas, rattlesnakes, copperheads, and moccasins. We have visited with them for hours, and I guess I have about all their secrets. It is a charming story—just wait.

WHEAT JOINT-WORM.

The insect that is destroying the wheat for J. L. Bell of others, of West Middletown, Pa., is the joint-worm, *Irosoma hardi*. Harr. A small black four-winged fly lays its eggs, often several, just above the joints of the straw. These absorb the juice, and cause the straw to harden and become deformed, sometimes a little enlarged. These so injure the stem that little or no grain is produced. Barley suffers, as well as wheat. In the fall, examination will reveal the larvæ in the straw. They pupate in the cells in the hard straw, and come out early the next summer. If Mr. Bell will put some of these straws in a bottle he will obtain some of the flies in the winter or spring, if kept in a warm room; later, if kept out in the cold. In thrashing, the joints often break off, as they are so hard, and come out with the grain. These hard pieces of straw, of course, contain the enemy. A good remedy, as these work in the lower joints, is to cut the grain high and burn the stubble; also, to collect the straws from the grain and burn them. Still better, we can usually rely on parasites to destroy these destroyers. There are little holes in the straws sent. These are openings where little parasites, which have destroyed the joint-worms, have come out. These holes, as also the experience all over the country, make it probable that the worst of the trouble is over. Very likely no signs of the enemy will appear next year; or, if so, the damage will be far less.

DISEASED GRAPEVINES.

Mr. C. Gere, East Springfield, Pa., sends me two pieces of grapevine which are very much deformed by a gall-like excrescence. It often kills the vines the first year, though some vines sprout below the disease and live. I do not know this disease. I do not find insects, and surmise that they have had nothing to do with it. It appears like the fungoid malady of the plum—black-knot—though this is green or gray. I presume it is fungoid in nature. If so, the remedy is, I presume, the same as for black-knot in plum—cut and burn the stems as soon as the disease appears. I have handed the specimens to Prof. L. R. Taft, our horticulturist; and if he gives me any additional light I will report. I should like five or six more of the stems. The knot is two or three inches long, and doubles the size of the stem, so it is very noticeable. One can readily believe that it would kill the vine.

COLORADO DATAMES.

Miss Ellen Stewart, Altona, Colorado, writes: "I send you a new and strange insect, the second of the kind I ever saw. Will you kindly describe it in GLEANINGS?"

This is another species of datames. I have described and illustrated one in my Bee-Keep-

er's Guide, 15th 1000, p. 432, Fig. 221. This one is brown, and smaller than the ones from California. The first one from California, the late Mr. Enos, of Napa, found killing his bees. This summer another was sent me from Southern California, and the same complaint—killing bees—was preferred. Has Miss Stewart noticed a like habit of this Colorado species? As will be seen by referring to the figure in my bee-book, these animals are most peculiar in their jaws, which can work laterally, while each jaw has vertical jaws which remind us much of the pincers on the first legs of a lobster.

This animal belongs to the spider sub-class—*Arachnoidæ*; to the scorpion order, which includes the true, false, and whip scorpions, and our grandfather gray-beards.

The family is *Solpugidae*, which is represented in the United States by only a few species. The most common one is *Datames pallipes*, Say. This is said to be common in Colorado, under "buffalo chips," and also to live in houses, where it feeds on bed-bugs. If this one had any show of a black dorsal line, I should think this Say's species. This one is brown, just the color of a bed-bug. The legs are lighter, quite yellowish. The tips of the falcæ, or jaws, are black. It is about one inch long. I am glad of this specimen, as it gives us two species of these remarkable animals in our collections. Who will send the next one?

SWALLOW-TAILED BUTTERFLIES.

The caterpillar sent by Luke Snow, of Lamar, Barton Co., Mo., and which feeds on prickly ash, is common all through the United States. It changes into a swallow-tailed butterfly, *Papilio chresphontes*, one of our largest species. It is black and yellow, the yellow in the form of a triangle. All of the papilio larvæ have forked scent-organs near the head, on the back. When disturbed they throw these out, which produces a rank odor. This must be offensive to both man and bird. The butterfly is one of the most showy of our American species, of which we have several. All are black and yellow, or black and blue. All have tail-like projections to the hind wings. A good time to catch the butterflies is in the early spring, on the lilacs. A better way is to feed the larvæ and rear the butterflies; then they will surely be bright and perfect.

GOLDENRODS.

The two species of goldenrod sent by Mr. C. Gere are *Solidago lanceolata* and *Solidago canadensis*. These are common species through the Northern States. I am not surprised to hear from Mr. Gere to the effect that both are excellent honey-plants. This fall all goldenrods have seemed to yield honey. I have found the goldenrods merry with bees upon every visit made to the plants this autumn. I should say that goldenrods are among our very best autumn honey-plants.

Hon. D. C. Leach, Walton, Mich., on the pine plains, says the bees are getting much honey from goldenrod. He finds they work steadily on *Solidago bicolor* and *Solidago nemoralis*, but hardly at all on *S. canadensis*. This is rather strange. Last week a gentleman wrote from Pennsylvania, and said they were working finely on *S. canadensis*. The same is true here. They are still working on all our species here. The hives are well filled, and we shall get several hundred pounds of surplus. The honey is very fine.

A. J. Cook.

Agricultural College, Mich., Sept. 25.

Friend Cook, it does me lots of good to hear you tell about handling these great horrid-looking worms and fearful-looking snakes as if they were kittens and puppies. In view of the

superstition in regard to curing diseases, and the weather, etc., I felt sure there was also much superstition in regard to animals. I have been told that ordinary striped snakes are harmless. Perhaps you have said so; but I find it almost impossible to prevent everybody around here from killing them as soon as they see them. I try to cultivate their acquaintance whenever I find them; and I confess that I begin to regard them, as you say, like kittens and puppies; and when they are doing great service in destroying bugs and insects, it certainly does seem too bad that we should be so blind to our best interests.

SELLING ON COMMISSION.

SELLING HONEY FOR LESS THAN THE PRICE
QUOTED TO PRODUCERS.

Friend Root:—I have been very much interested in the articles on shipping and selling honey, by the commission men, and I am sure that those who sell in that way can profit by studying said articles closely. Now, I know there is a large portion of the people who believe that all or nearly all commission men are up to tricks, and make much of their money by misrepresentation. While I do not belong to this class of people, I have one fault to find with all commission men that I have dealt with; that is, quoting a certain price on honey, and then, when they receive it, selling at a less price, although the market quotations showed no decline in prices at the time. To illustrate:

We write to a commission man in Kansas City or St. Louis for quotations, and in reply we receive a very polite letter, stating that they have special facilities for handling honey, and can handle ours to advantage, etc., and quoting a fair price *to-day*. We ship the honey, and receive a card or letter stating that it was received all right; and after waiting a month or two we write to see what has been done with our honey, and find it has been sold for a cent or two less per pound than formerly quoted. If not taking too much space, allow me to relate one or two such transactions.

I might here give some of the correspondence, to show that I am unbiased in my opinions, but that would only be taking time and space for only a small purpose. Last year we wrote to Kansas City for prices, and were quoted 16 cts. for nice comb, and were advised to ship immediately. We did so, and soon received a notice that the honey was received in good order, and was very nice. Soon we were advised of a decline, and our man thought best to hold it for better prices; and finally, after four or six weeks, our honey was sold for 14 cts., which netted us something over 11 cts. Had we known it, we could have got 15 cts. net for this same honey, without any great effort to dispose of it.

Last February we shipped 3 cases, 6 60-lb. cans of extracted honey, to Omaha, Neb. The party there had quoted it at 9 cts. per lb. After two months they had sold one 60-lb. can at 9 cts., and allowed us 7 cts. for the other 300 lbs., and charged us only ten per cent commission. That is, they did not report the 300 lbs. sold, but I presume they considered it sold to themselves at 7 cts., and charged us only ten per cent for making the sale.

Now, friends, I try to have charity for all men, and especially for those with whom I have dealings: neither am I much given to complaining and fault-finding; yet I should like to know why it is that honey *always* declines in price

just *after* we ship, for we have invariably received a less price for our honey than that first quoted. This has been the case so often that we have about abandoned the practice of shipping on commission.

And now, brother bee-keepers, are not we somewhat to blame for crowding our honey into the great market centers, such as Kansas City, St. Louis, Chicago, Philadelphia, New York, etc., thus running the supply beyond the demand, and cutting down the prices in these places? Then when we go to a small town and try to sell honey at a fair price the merchant will show you a St. Louis price current, quoting Southern honey in barrels at 5½ to 6 cts., and sometimes even lower. I tell you, you have to talk like a good fellow if you make a sale at a fair price. Yet with all this, the writer sold, in small towns along the Mo. Pacific R. R., about a thousand pounds of extracted honey at 10 cts. per lb., in five-gallon cans. The can went free, and in one-gallon cans we charged 12½ cts. for the honey, can free.

We also could have sold more comb honey than we could supply, at 15 cts. net, and all of this was sold where I presume there was not 100 lbs. sold before I went there. We intend selling all or nearly all our honey this way in the future. Why can not you do the same? Keep more of the honey out of the great market centers, and thus keep it up to a living price.

Bluffton, Mo., Aug. 13.

S. E. MILLER.

Friend M., I know there is a good deal of encouraging people to expect something they do not realize, in getting trade in all departments of business; but I am sure it is not a profitable way. You will notice that I strike upon the same subject in my present Home paper; but we should be careful about being too general in our charges. There are commission men in Cleveland who sold honey at a larger price than they encouraged us to expect, though this is the exception and not the rule. When you find a commission man who has once done this, hold fast to him, for you have discovered a treasure.

NYSEWANDER'S HONEY-EXHIBIT.

AN ATTRACTIVE DISPLAY.

I herewith give you a glimpse of our honey-exhibit, made at the Iowa State Fair. Notwithstanding the agricultural hall is large and commodious, the room always seems limited, and the exhibitor is sometimes required to make the room in height what it is lacking in length. This is true with the exhibit shown. It is about 14 feet in height and 25 feet in length, comprising extracted and comb honey, supplies, etc. The amount of honey represented is about 4000 lbs. We were required to place most of the extracted honey so far above the heads of the people that shelving had to be largely dispensed with to show up the glass jars to the best advantage. The larger portion of these were therefore strung on wire. While the row of jars did not appear quite as regular as if shelving had been used, there was nothing to obstruct the light at the back or the view in front, and this more than made up for the slightly irregular appearance, and the clear jars of linn honey showed up very beautifully.

By the way, the whole exhibit was purely of linn honey. The clover-fields that were early so promising did little more in this vicinity than to fill the hives when they suddenly with-

ered under the influence of hot winds and dry weather.

There were about 2800 lbs. of comb honey. It was exceptionally white and fine, having been made in a short space of time, and taken off from the hives as soon as finished. You will notice that it is mostly in 24-lb. shipping-cases, the rest being 12-lb. cases. While these do not show the honey quite as well as the 48-lb. case, when it comes to shipping and marketing they are much safer, and more popular with the trade.

The supplies were arranged in convenient view, and consisted of every thing used by the bee-keeper, though the picture doesn't fully show this portion of the exhibit. However, you will notice, beginning at the left-hand side, a few smokers with numerous other small articles, which were placed on the top of a pyramid of 60-lb. cans of extracted honey, only the top corner of which is shown. Following along are the different sizes and styles of the Novice honey and wax extractors. Back of these may be seen smokers, foundation, drone-traps, and perforated zinc honey-boards. To the right of the central card is a pyramid of choice beeswax, made of small cakes. In this shape we find it to be a very marketable article. The cakes are of such a size as to retail at 5 cents, and we wholesale quite a good deal of it in this form to the stores. Next may be seen sprigs of a bunch of Japanese buckwheat in bloom, and the best 20 lbs. of extracted honey. The lid of the solar wax-extractor, which is thrown back, is noticeable, and the rest of the supplies in view are, a copy of the A B C book, foundation-mill, and sections, which are easily recognized. J. S. NYSEWANDER.

Des Moines, Ia., Sept. 15, 1890.

Friend N., your idea of hanging honey-pails and tumblers on a wire is quite an item; and if you are the first one to inaugurate it, we owe you a vote of thanks. We congratulate you on the neat placards explaining and advertising the different items. Very likely the whole display will give many helpful hints to others in arranging like exhibits.

FOUL BROOD IN CANADA.

AN EYE-WITNESS RECOUNTS THE EFFECTIVE WORK DONE BY THE FOUL-BROOD INSPECTOR.

Any one who has spent a few hours with Mr. McEvoy in the discharge of his duties could hardly fail to be convinced of the necessity, in the interest of bee-keeping, for the surveillance of foul brood. I had long been satisfied in my own mind that protection ought to be given to this industry, of such a nature as to insure the man who embarks in it to make a livelihood, that his neighbor who has nothing at stake, comparatively, would not, through ignorance or otherwise, cultivate foul brood beside him, and thus jeopardize his existence as a bee-keeper. That impression, which has been deepening on my mind for years back, was immensely emphasized by the result of yesterday's ride; and, Mr. Editor, you may put your own comment underneath whatever way you please; but when I say that a large class of people—among them the non-reader, and the one-or-two-hives-for-honey-for-own-use folks—should be strongly discouraged, I think I say it advisedly, and that the following will bear me out.

After a drive of a couple of hours we arrived at a certain comfortable-looking village situated picturesquely amidst the hills, and there called upon the principal bee-keeper, the resi-

dent minister of the German Baptist church. We found him a man of intelligence, and particularly well up in matters pertaining to this industry; a student of the German, English, and American authors. He has for years used a shallow hive with a hanging frame, the same dimensions as the Heddon frame, and got the idea from accounts by German authors of a similar hive used in Germany. In fact, he says that, when Mr. Heddon gave his invention to the world, he wrote, informing him that he had already, the previous season, been using the same hive, only with a hanging frame.

When asked about foul brood he said that there had been some in his yard, caught from neighbors, but that it was now away; that he cured it by shaking the bees on starters, and replacing these by others at the end of three days, when he fed the bees, medicating the feed with salicylic acid and borax. No disease was found in his yard, and the place was the very perfection of order and neatness.

From there a visit was made to a blacksmith neighbor of his, scarcely 200 yards away, where only two hives were found, he having sent a number some miles off to a son's place. One of these two was very badly diseased, and the other somewhat less so. Another call in the village was made on a party owning one hive, and it was found to be on its very last legs with the disease.

As one of these two parties was reported to have sold many cases of foul brood they both were requested to have a bonfire at night. Mr. McEvoy then went across the street and asked the minister if he would go over and see that these men did what they were ordered to do. The minister very willingly promised to do so. He was very much alarmed when told that it was so close to him; and, with feelings of the deepest regret he said, "Oh dear! oh dear! after all my trouble in melting combs, and doing all I could to keep it out of my apiary—just see the risks I have to run with my neighbors who won't do any thing." The inspector replied, saying he would protect him, and make them clean out the disease.

Leaving the village we went to blacksmith No. 2, a couple of miles away, to whom blacksmith No. 1 had sold bees some time ago; and in the second hive looked at, the disease was found in a very malignant form and degree. This man has somewhere about 30 hives. The conversation which took place here was something like this:

"Say, mister, would you come up here?" (spoken from the upper level door behind the smithy).

"What for?"

"I want to see your bees." Up he comes.

"I'm the government inspector; appointed to look after bees and see that there is no foul brood among them."

"Guess you won't find any here."

Guesswork in this business is rather suspicious and suggestive.

"Oh, no! I don't expect to. Well, we'll go and see, any way. Do you take any journal?"

"No."

He was shown the foul brood, and warned and instructed about it. He was then advised to ask the assistance of our minister friend to help him get rid of the trouble.

Leaving here we passed down the road a mile to a farmhouse where was a small collection of hives of the ancient Mitchell and more modern Jones varieties. Some were inhabited, but more without tenants. No foul brood appeared here; but in one hive large pieces had been cut out of two of the back combs, and the next frame showed a few dead larvæ. The owner being away in the fields at a distance plowing,

time did not permit of interrogating him regarding the mutilated combs; but as a precautionary measure, word was left advising him to "take up" the hive this fall for its honey.

Further along a call was made where half a dozen Mitchell hives were sitting on a sloping lawn with a "list" to south that was calculated to call to mind the leaning tower of Pisa. The guid-wife took us for tramps, or agents, and, in absence of the guid-man in the fields, assumed the defensive.

"I don't let any one interfere with my bees. I run them myself," says she.

Mr. McEvoy indulged in a smile, passing the remark aside that this was the second time he had been refused liberty to see bees in the province. Our good lady friend became mollified when she was informed that no less a person had called upon her than a government official, and then came down and assisted in the somewhat difficult operation of dissecting one of the hives, apologizing all the time for her apparent discourtesy. No disease was found here.

The shades of evening were about to close over the beautiful landscape, and we headed off for home, having found three yards, out of six visited, badly infested with the vile disease.

Had time permitted following the other bees of blacksmith No. 1 to where they had been located, no doubt the trouble would have been found there also. We heard of a case where a party having foul brood extracted his honey and sold it in the grocery where another bought it and fed it to his bees, giving them the disease. One would naturally conclude, also, that foul-broody bees have been passing from one to another around here. I had the unfortunate experience myself, some years ago, of buying these, and know how exceedingly disappointing it may be, especially if no reparation is made, as in my case, and now I appreciate the Foul-Brood Act.

Our minister friend told us of having set up his son in the business, a year or so ago; and how, after he had just started, he got foul brood from his neighbor which cost him \$400 before he had it eradicated.

Galt, Ont., Can., Sept. 4. E. W. McDONNELL.

Well done, friend M. You certainly did a good thing when you started out on that visit, and a better thing when you reported it to GLEANINGS. Now, if we don't soon have like inspectors looking over the whole United States, and, in fact, the rest of the world, and doing just such effective service as you describe, it will certainly reflect on the bee-keepers of the world. Let us go and do likewise.

FOUL BROOD IN AN APIARY OF 125 COLONIES.

THE DISEASE COMPLETELY CURED BY THE PLAN GIVEN IN THE A B C, BESIDES 7 TONS OF HONEY AND AN INCREASE OF 65.

Friend Root:—You may remember that, in March last, I wrote you in regard to a remedy for foul brood, and you recommended the last issue of the A B C, which I purchased. I have been working an apiary of 125 stands, all of which had foul brood. I commenced transferring them about March 20, using the same hives and frames, but first boiling them. After putting about 12 stands in clean hives, on 4-inch strips of foundation, and confining them 24 hours without food, and finding they had done nothing, I gave them $\frac{1}{2}$ pint each of honey taken from the diseased bees, but boiled, when they

commenced to work. The strongest received no more, but the weaker ones were fed a few days. The remainder of them I treated less carefully, as I saw they would not work till the honey taken with them was digested. I transferred all I could each day, brushing all the bees from the combs into the new hives, and placing the combs into boxes for the purpose, furnished with sliding covers, and, when full, wheeled into the honey-house. At night, all that had been transferred during the day were moved about 50 yards, and given their liberty. As often as the combs and hives became too numerous, the frames and hives were boiled, and the combs made into wax.

After the bees were all transferred I used Muth's remedy, as given in your issue of A B C, 1878; viz., $\frac{1}{4}$ ounce each of salicylic acid and borax, dissolved in 1 pt. of pure soft water, and sprayed the combs. I used this remedy once on each colony, and have effected a complete cure.

About one year ago I transferred a few stands of bees which had foul brood, without the use of any medicine, and they are healthy to-day. If I treat any more bees having foul brood I shall use Muth's remedy, as I think it is a benefit to them. I have increased the above apiary to 190 stands, and taken 7 tons of extracted honey.

HENRY OTTO.

San Jacinto, Cal., Sept. 30.

THE INTERNATIONAL BEE-KEEPERS' ASSOCIATION.

WHERE SHALL WE HOLD THE ONE AFTER THE MEETING AT KEOKUK?

The following is the copy of a letter which will explain itself. That I might go ahead understandingly I sent copies of the same to the ex-presidents and other officers of the American Bee Association. The letter is as follows:

At the bee-keepers' convention at Plum Bay, N. Y., we had a pleasant time. The entire shores of the most beautiful Lake George were covered with historic reminiscences. Mountains rise abruptly out of the water, and the scenery round about is indescribably beautiful. The water is clear—so clear, indeed, that objects can be seen sometimes forty feet beneath the surface. At the point (Plum Bay) where the bee-keepers camped, there is said to be a man-of-war sunk. It lies in a depth of forty feet of water, and yet I am assured that, on favorable days, its hulk can be quite distinctly seen.

At one end of the lake is Fort William Henry Hotel, on the spot of the old fort of that name, and, at the other end, Ticonderoga. Near by are two or three celebrated battlefields.

I have taken pains to mention some of the natural attractions of Lake George, and now, then, to my point:

Two first-class bee-keepers, Messrs. Andrews and Lockhart, own several cottages and a considerable portion of the shore bordering on the southeast. They are very anxious that this camp of bee-keepers should be an annual affair, as it is situated between the New England bee-keepers and the New York State bee-keepers, and is easy of access to some of the most extensive bee-men in the world.

Still further, while we were in camp this time, we were discussing as to whether this might not be a very desirable location for the International Bee-Association, to be held the year after the meeting at Keokuk, Iowa; namely, during the winter of 1891-'92. Along with the natural attractions, it is right in the

center (if we except California) of the most extensive bee-country in the world. Not many miles away are bee-keepers owning their 300 and 400 colonies. Then there are Messrs. Elwood, Hetherington, Hoffman, Tunnicliff, Larabee, Martin, Manum, Crane, L. C. Root, Knickerbocker, Lockhart, and Andrews, and a good many others that are extensive bee-keepers. As it is one of the policies of the International Association to migrate, I merely suggest that it might be well to consider the advisability of holding our next International on the borderline of the Northeastern States; namely, at some point on Lake George. Mr. Lockhart offers the use of his cottages; and if anybody knows how to entertain bee-keepers, he does. His cottages are right on the shore of a most beautiful bay.

Now, whether we meet at Lake George or not, it seems to me that it is expedient for us to begin to consider the location of the International in 1891-'92, so that at the next meeting at Keokuk the members may be prepared to vote intelligently and understandingly. I told the bee-keepers assembled that I would write to some of the ex-presidents of the association and other officers, and learn what they thought of it; and if they all agree that it might be advisable to bring the matter up in print, that Mr. Newman, Mr. Hutchinson, and ourselves, would properly present the matter in our respective papers. I send a copy of this letter to Drs. Mason and Miller, Hutchinson, C. P. Dabant, R. L. Taylor, Prof. Cook, and perhaps one or two others.

After presenting the above to the readers of the *American Bee Journal*, the editor says:

We are very much in favor of holding the next meeting of the International Association at Plum Bay, N. Y., if it can be held during warm weather, and will do all we can to get it located there.

The following are replies received from the other representative bee-keepers:

As regards the place of holding the International meeting of bee-keepers in the winter of 1891-'92, I haven't much choice, except to have it as near *my* location as possible. Selfish, did you say? All right, then; let it be held where its best interests may be subserved. I love to attend the meetings; but, being poor, I can't afford to go very far, and I fear I shall not be able to go to Keokuk, but I *do* want to *so* badly! I am sure I don't know whether it is or is not advisable to meet at Lake George. You give but one good reason for so doing, and that is the proximity of so many large bee-keepers. The beautiful scenery, bay, historic spots, etc., cut no figure at a bee-convention, especially in the winter, when the ground may be covered with from a few inches to a few feet of snow, and the clear waters of the bay and lake with the same of ice. If held in October it would be different. Some town or city that is easy of access by rail seems to me to be the most desirable location. I had been thinking that perhaps Buffalo or Rochester would be a good place for the next meeting after Keokuk, for the reason that either location is readily reached from the East and West, and by the Canadians. Our meetings have not been selfish as regards places of meeting, and have done what was thought to be for the best interests of the society.

Auburndale, Ohio, Sept. 22. A. B. MASON.

I for one am quite willing that the next meeting of the I. A. B. A. should take place at some such point as you describe. It is evidently best for all that the I. A. B. A. should not meet twice in the same place for a number of years,

and it is time that the N. E. bee-keepers had their turn; so you may count on my support, and I must say that I am very glad that you have thought best to discuss this question before the Keokuk meeting. This point having been raised, there will be less disappointment from parties who might want the meeting in some other direction. There is only one question that I wish to raise. If this meeting of 1891-'92 is located there, would it not be best to hold it early in the fall, so that our bee-men may have a chance to enjoy the scenery by a few rambles? C. P. DADANT.

Hamilton, Ill., Sept. 19.

I lectured to the bee-keepers in N. E. N. Y. several times last winter, and I know they are wide awake. I should think your plan a wise one. I believe a meeting held on Lake George in August would be excellent. Why not? Bee-keepers are not very busy in August.

Agricultural College, Mich. A. J. COOK.

If we decide to hold the meeting at Lake George, it should, of course, be held early in the fall, say immediately following the general harvest of farmers and bee-keepers, and before the bees are put into winter quarters. Perhaps the first of October would be a good time. At any rate, we can talk that over at the convention; and if it should be decided to hold the meeting at Albany it might be advisable to meet later in the fall, or along in the winter. I should not think of holding it at Buffalo, because we have already had one meeting recently in that vicinity; namely, at Brantford; and as the policy of the International is migratory, it ought to go as far as Lake George, or the line of the New England States. E. R.

RAMBLE NO. 30.

IN STEUBEN COUNTY.

Mr. Sprague, Mr. Bowen, and the Rambler made a friendly call upon the great bee-man of Steuben Co., Mr. Wm. B. Stephens, of Stephens Mills. At the time of our call, Mr. S. had 260 colonies, located in three apiaries. We found

CHAFF HIVE USED BY MR. W. B. STEPHENS.

him and his son ready to talk bees, and we had quite a convention. His apiaries are run prin-

cipally for comb honey. In the apiaries at and near home, the honey resources are limited to clover and buckwheat, while his apiary over in Allegany Co. has the advantage of basswood. Mr. Stephens and Sprague both prefer black bees. Much buckwheat is sown in Steuben Co., and on that account the blacks are preferred. The L. hive is used to a large extent, but we saw quite a sprinkling of Heddon hives. We

who believes in a diversified pursuit. He runs a farm, an apiary, a Brahma poultry-yard, a flock of peacocks, and a stable of Percheron horses. This carrying of eggs all in one basket does not agree with Mr. C. If the season blasts his hopes on one or two things, the others are successful, and he is happy.

While riding along we were shown the residence of an old-time bee-keeper, Mr. Hugenor, who had no end of peculiarities. While the bees were swarming he constantly repeated in a monotonous undertone the following "charm:"

Flutter, low flutter, nigh;
Busy bee, don't go high;
Whirl around the busy queen,
Alight down here upon the green.
Steady now, my hearties, steady;
Here I have a hive all ready.

The bees always alight low, so *they* say. Another belief quite common in the neighborhood, and which came from the same source, is, that bees choose their course on the first of May. This solves a problem that has been of much vexatious study for the Rambler. To diffuse themselves evenly over a given field must necessarily require preconcerted action, and that explains why some colonies outdistance their neighbors in honey-gathering. The 1st of May is a great day in beedom. We send you a picture of our happy and wise old friend. No doubt he would be pleased to give much information upon the subject; but, come to think of it, he, like old Grimes, the good old man, is—*dead!*

Having learned all we could about the bees and the people of Steuben Co., we bade our relatives and transient friends good-by, and ac-

Uncle Hugenor

were shown a very cheap chaff hive taking an L. frame. It had double walls, packed, and in winter a cushion is laid over the frames and a light case slipped over all. Mr. S. was so well pleased with the working of these hives that several were under construction. In the honey-house we saw a Novice extractor and an old-style Peabody, which is strong evidence that Mr. S. has been long in the business. A charming point about Mr. Stephens' location is, that his entire honey-crop is sold in the home market.

Hornellsville, located only a few miles distant, is a smart and rapidly growing town of about 10,000 population. The principal grocers are supplied regularly; and, as long as he can supply the demand, California and other foreign honey does not find lodgment here, but is sent on to other cities. Extracted honey was slow to sell at first; but by putting a good quality upon the market he finds the sale increasing. His good home market will induce him to increase his apiaries, and extend the business. Having two energetic sons to help, he is well equipped for the extension.

Cellar wintering is practiced to a considerable extent, though outdoor wintering would be preferred, and is resorted to in out-apiaries.

We discussed the many qualities and peculiarities of extracted honey, and found our friends believing strongly in the idea that candied honey could be made nearly dry and powdery by draining; but the Rambler, having tried the draining process, is inclined to the belief that a current of air is necessary to drive out the moisture. All of this drained honey is usually found near stove joints or on the surface. If we had a shop in which a blower was running we should certainly turn a current of air through some candied honey, and watch the effect. If one temperature did not have any effect we would try another and get a range of temperature from warm to icy cold. Will some one try it and give us evaporated honey?

Our next call was upon Mr. Samuel Cotton,

HAPPY CONDITION OF THE RAMBLER.

cepted the invitation of Geo. Silsby to ride to Wallace's Station with him in his barouche. Though the roads were muddy and rough, we had a delightful ride. We send a sketch, showing the happy condition of the RAMBLER.

Friend R., you have actually found a bee-keeper who is well pleased with the outside protecting shell we described on page 698 of our last issue. I believe there is something in it yet, although the senior editor threw cold water over it. What we want is something that will enable bee-keepers to use the single-walled hives we already have in use, with a little more expense added, for outdoor wintering. I hope Mr. W. B. Stephens, if he sees this, will enlighten us more concerning it.—Uncle Hugenor looks as though he might be a firm believer in a charm for calling down swarms. No wonder his bees alighted low, for they could not do otherwise.—The happy condition of the Rambler, as shown in the above, calls vividly to mind some of my experiences. I thought it was bad

enough to ride in a spring wagon over some of the York State roads; but to sit in a lumber-wagon without springs, and that on top of a barrel, must have been—ah! well, exhilarating and exciting. Your picture leaves us in doubt as to whether you or the barrel arrived at destination “right side up with care.” ERNEST.

RECENT DEVELOPMENTS

CONDUCTED BY ERNEST R. ROOT.

THE DOVETAILED HIVE FOR 1890 AND '91.

I have already explained that my trip to the East was made largely for the purpose of ascertaining how the mammoth bee-keepers of York State dispense with burr-combs and honey-boards. Scarcely secondary to this was the matter of fixed distances. I visited some 25 or 30 representative apiarists, after whom the lesser lights follow. The former own an aggregate of perhaps 50,000 colonies, and manage them successfully without using honey-boards; and the wonder to them was, why they should be deemed necessary by the Western bee-keepers.

Now that I have come home, and the enthusiasm has somewhat subsided, so that I can take a somewhat cool view of the situation, I am thoroughly satisfied that we should do beginners a great harm by offering them slatted honey-boards* next year, when there is something so obviously better and cheaper. Your “committee” (as one of our subscribers has already begun to call it), comprising J. T. Calvert, business manager; J. S. Warner, our superintendent; A. I. Root, the “big boss,” as he is familiarly called, Dr. C. C. Miller, and your humble servant,† after talking the matter over in all its bearings, have decided to offer the Dovetailed hive the coming year without the honey-board; and, in lieu of it, thick top-frames in the brood-nest. The bee-keepers of the East do not exactly use this style of frame, but they use a top-bar heavier and wider than those of the West ordinarily do. Their bars are, as a general thing, from $\frac{1}{2}$ inch to $\frac{3}{4}$ thick, to about an inch or a little over wide. To be on the safe side, our top-bars of the hanging frame in the new Dovetailed hive are to be $1\frac{1}{2}$ wide and $\frac{3}{4}$ thick. The engraving below shows the frame as well as the hive.

THE NEW DOVETAILED HIVE.

With the exception of the thick-top-bar frame and the absence of the honey-board, its general appearance is the same as before. But we have changed the hive a little; or, rather, we have made its inside width $12\frac{1}{2}$ inches instead of being $11\frac{1}{2}$ as before. You will remember, Dr. Miller spoke of the advantage of having an eight-frame hive wide enough to take in a follower on $1\frac{1}{2}$ spacing. While we objected to it at the time, your humble servant, while on his Eastern trip, saw that the advantages of the movable follower were so decided that he at once recommended to the committee the widening of the hive; “for,” said he, “if fixed distances ever get to be the rage (and it looks as if they would be in time), either a follower or an open-side hive will be indispensable. Even for hanging frames it will be a very great advantage.” Mr. Calvert suggested that widening the hive would also necessitate widening the super. And this will permit us to use wooden separators with $1\frac{1}{2}$ sections, or 7-to-the-foot sections without separators. Your committee then decided, with Dr. Miller’s indorsement, to widen the hive. Some of you will argue that this will make confusion; that old hives will not be interchangeable with new ones. Oh! yes, they will. With beveled edges it would not do at all; but with square edges the new bodies will project only $\frac{1}{4}$ inch on each side over the old bodies, the length being the same. With this very slight change, you that already have the old hives would decide that the very great advantage to new purchasers is such as to warrant us in making the change.

FIXED FRAMES FOR THE DOVETAILED HIVE.

I think I may say, that, with very few exceptions, the very best bee-keepers of York State use fixed distances; and the favorite frame seems to be the closed-end and the Hoffman. One is used in York State about as much as the other, and both have peculiar advantages; and as it is a fact that these leading lights in apiculture can handle these frames as rapidly as the hanging frames, or, as Mr. Elwood calls them, the “swinging” frame, is it not wise to let those who wish to follow in the tracks of Elwood, Hetherington, Hoffman, and others, do so if they wish, and yet use the Dovetailed hive or the hive they already have in use? Mr. Calvert assures me that fixed frames, either the Hoffman or the closed ends, will cost only 5 cents per hive more than the same hive with hanging frames; and as our United States is made up of bee-keepers of all shades of opinion and preferences, we have decided to accommodate all if possible.

The Hoffman frame is already familiar to our readers; so is the closed-end; but as to how it should be used in the Dovetailed hive or any hive adapted for hanging frames, may not be altogether clear. Well, instead of having these frames *stand* on inside projections, we propose to have them *hang* in an ordinary hive rabbet like any suspended frame. The top-bar, instead of projecting, is sawn off even with the end-bar, and a good substantial blind-staple will be driven into the end of the top-bar just the right distance for a bee-space between the top of the cover and the frames. Mr. Calvert has made a diagram, which, being photo-engraved, is shown on the next page.

B, B, etc., shows the body; C, C, the super; A, A, the cover; A, A¹, the bottom-board; f shows the closed-end frames, and f¹ the thick-top hanging frames; k the comb-guide, and l the groove with the comb-guides left out for wiring. A staple is driven into the top-bar at k, and hangs in the rabbet, as seen in the diagram at the right, like any ordinary hanging

* This does not apply to queen-excluders.

† We have also had some correspondence with the W. T. Falconer Co.

frame. This method of using closed-end frames in a tight-fitting box is the same as that used by Mr. Tunicliff, of Van Hornsville, and Mr. Smith, of Starkville.

DIAGRAM OF THE DOVETAILED HIVE.

□ While the Quinby method of using the closed uprights (a hook under one corner so as to hold the frame while standing) may be preferred by some, there are so many L. hives of the hanging frame type, that it will be necessary, in order to use closed ends, to use Mr. Tunicliff's plan.

In order to reduce propolis accumulations, I noticed that Mr. Tunicliff uses Mr. Manum's thumb-screws. Mr. Smith, of Starkville, adopted a form of a wedge. Either method will compress the frames, and so reduce the amount of propolis that would ordinarily be secreted in the interstices between the closed ends. Thumb-screws, when they stick outside of the hive are objectionable on account of being in the way, and we have decided to adopt a wedge in connection with a follower, so that the closed ends will be compressed together, and yet leave the outside of the hive plain. In York State and Vermont I noticed that the large bee-keepers, as a rule, used a follower, in connection with a wedge or thumb-screw, to press the sections together, and at the same time facilitate the removal of sections. The foregoing diagram will illustrate the follower. *i* is the follower pressed against the section-holders *h, h, h*. To key up, a stick $\frac{1}{4} \times \frac{1}{2} \times 12$ is let down perpendicularly, the thinnest way between the follower and the side of the hive. It is now revolved so that the follower, instead of being $\frac{1}{4}$ inch from the hive side is pressed $\frac{1}{2}$ inch from it. The projecting end is now pushed down below the side of the hive, out of the way. To loosen up, reverse the operation as above; i. e.,

DOVETAILED PACKAGES FOR SHIPMENTS.

pull up one end of the stick to a perpendicular, turn it around flatwise and withdraw, and the sections are loose. Where fixed frames are used, the same keying-up arrangement will be used in the brood-chamber.

The engraving above shows very nicely a complete package of five Dovetailed hives ready for shipment. The inside furniture, cover, bottom-boards, etc., are all boxed inside, without using an ounce of crating, or in any way interfering with the usefulness of the material afterward. Besides, the sides and ends, as we have before explained, are held compactly by means of four cleats, that are just the same as the inside of the dovetails. The Dovetailed hive is as cheap as any, I think I may say, without boasting, ever before made, comprising from five to ten hives complete.

A BEE-SPACE AND WHAT IS RIGHT.

While on my trip I took pains to investigate the matter of a bee-space, and its relation to burr-combs. I feel pretty well satisfied that $\frac{1}{8}$ is too much. Mr. Elwood, who was never troubled with burr-combs, told me that he uses a bee-space $\frac{1}{4}$ inch, a little scant if any thing; and all those bee-keepers who had little or no trouble with them, I noticed, were using and recommending this scant quarter-inch bee-space. Those who do not have burr combs are the ones competent to give a correct answer to this. The Dadants, and Mr. Secor, and others of the West recommend this bee-space. We decided, therefore, to make the Dovetailed hive in accordance therewith.

BEEES AT WATERING-TROUGHS.

DR. MILLER SUGGESTS TWO REMEDIES FOR TWO OF THE TROUBLES IN BEE-KEEPING.

In your answer to John Burr, page 713, friend Root, you seem inclined to think that bees at a well or watering-trough do no great harm. My bees, at least, have been very troublesome. At the Wilson apiary there is a watering-trough at the well, and for the last two years the bees have taken possession of it to such an extent that it had to be abandoned as a place for watering horses, and another place used some rods distant. No doubt you will say, "Why, what harm did the bees do?" Well, I'm not sure that they ever did any harm; but the horses wouldn't drink there, and that was harm enough. I have tried a number of times watering my own horse there. If very thirsty I could get him up to the trough, and perhaps he would plunge his mouth into the water in a kind of desperate manner, but, generally speaking, he would just stand and snort at the bees without offering to drink. I suspect, however, that bees floating on the water got on the horse's lips and stung or at least tickled them. This summer another trough was placed between this trough and the apiary, provided with comfortable floats and all that, and it secured some patronage, but the old trough held the most of its custom. If the old trough had been left dry for a few days, or had been entirely covered up, the case might have been different; but it was pumped full every night to cool the cans of milk. At the home apiary the bees are inclined to annoy every year by getting into any water left standing at the well, and even going into the pump itself, making it difficult to get a pail of water without drowning bees in it. A six-gallon crock of salt water standing a rod away, filled with sticks of rotten stovewood, has seemed enough attraction to keep them away. But it is important that any thing of this kind be started early in the season. Let

them once get into the habit of going to a certain place, and they don't like to change. This summer, before I noticed what was going on, they had commenced visiting the pump, alighting on a half-barrel that stood there with water for the stock. I moved the half-barrel away a little, and was careful to allow no water to stand in anything else. After a day or two I set the half-barrel about a rod from the pump. I put a piece of board in the middle of it, and then covered the whole with a gunny-sack. The gunny-sack sank in the water and kept moist for some distance out of it, and this seemed to just suit the bees. I threw in a handful of salt, so it would not breed mosquitoes, and because I thought the bees liked it. Since then the bees have not troubled at all, although water has stood in pails most of the time at the pump. I recommend for trial a tub or half-barrel covered with some kind of coarse cloth.

GETTING BEES TO EMPTY COMBS SPEEDILY.

Until this year I should have answered W. R. Tate about as you have done on page 716. As you know, I have practiced letting the bees clean out sections in the fall by simply setting them outdoors and covering them up with entrance for only one bee at a time. This works satisfactorily so far as the sections are concerned, but you have no control as to which colonies get the honey. Placed over a colony, the bees, as you say, may empty it in a month; but if sealed, and there is no scarcity of stores in the hive, some of it may be left all winter. Now let me tell you how I have reduced the time to two or three days. I have just been to look at some sections that were given to the bees 24 hours ago, and I think all the unsealed honey is cleaned up, and they are working at the sealed. If I had uncapped it I think that part would have been emptied first. The sections to be emptied were in T supers, but brood combs could be emptied in the same way. I lifted the hive off the bottom-board; put upon the bottom-board two supers of sections, one on the other; on top of these an empty super, and on top of this I returned the hive. Every thing was bee-tight at the bottom to prevent the entrance of robbers, and you will see that the entrance of the hive was raised some 12 inches, but this troubled the bees very little. You will see that the empty super made a space of several inches between the bottom-bars and sections. This is essential, for I tried it without the empty super, and it didn't work. I also tried the empty space over the hive, but it didn't work. The two essentials are, putting the combs *under* the colony, and having a space between them and the bottom-bars.

Marengo, Ill., Oct. 6.

C. C. MILLER.

Well done, old friend. Your remedy for bees around the pump is something like the way physicians work when they apply a blister or a plaster—a counter-irritant. The trouble is, your tub or barrel will not receive the attention that the average pump or well does; and then the bees will go where there is the strongest inducement. I am glad of that suggestion of yours, that a handful of salt will prevent the water from breeding mosquitoes; but are you sure that they like water that has been standing a long while, just as well as that fresh from the bottom of the well? I know they sometimes seem to like stagnant water best; but I never felt quite satisfied in regard to it. Is it not because the stagnant water is easier to

find than fresh water? Now, if keeping bees does annoy people around their pumps and wells, it is a matter that should be looked after. When people go to the expense of providing plenty of good water, with pumps and troughs to match, they ought to have the undisturbed benefit of it.—Since you mention putting the sections of broken comb at the entrance, *under* the colony of bees, instead of *over* them, it rather seems as if somebody had before suggested it. Is any one smart enough to tell us where it occurred in the back volumes of this or any other bee-journal? And, by the way, doesn't the above experiment indicate that the best place for a feeder is under the brood-nest?

DISCRIMINATION IN DISCOUNT.

BUYING BY PIECEMEAL, OR BUYING BY WHOLESALE.

You state in your catalogue, that any one sending an order for a large amount of goods can have them at a discount. It seems to me the poor man who is not able to buy in large amounts should have the benefit, as the rich one is able to pay for his goods; but it seems to be the rule to make the rich richer and the poor poorer. J. R. COMSTOCK.

Morrilton, Ark., Sept. 1.

Friend C., this matter has come up a good many times, and quite a number of the friends have seemed to think that we were unfeeling and forgetful of the needs of those who have but little, and must buy in small quantities. One friend even went so far as to say he did not see how a man could be a Christian and refuse sell to a poor man one pound of sugar at the same price he charged a richer one for 100 lbs. Now, those who make such statements are certainly thoughtless, and have not looked into the matter carefully. The friends who have tried retailing honey know how it is. After any bee-keeper has sold 100 lbs. of honey, a pound or two at a time, if his time be worth any thing he will say at once that he would rather have 8 or 9 cts. per lb., and sell it all in one lump, making one transaction of it, than to have 10 or even 11 cts. weighing out a pound at a time. Now, this is true of every commodity to a greater or lesser extent; and when it comes to keeping books, and charging up a pound or two pounds at a time, and taking the chances of getting your pay, etc., plain common sense dictates that a lower price by the lump, especially if it be a cash-down transaction, is by far to be preferred. Why, dear friends, the whole world is groaning under the burdens imposed as a consequence, because so great a part of the world will persist in buying a little bit at a time. My wife was greatly astonished a few days ago when I told her that a good many customers for our wagon buy half a peck of potatoes at a time. Years ago we decided in our household that we *could not stand* the wear

and tear of purchasing in little dribs. Suppose you wait till the sugar is clear out; then you send to town for a couple of pounds. If there are several other little items, the sugar is often forgotten. So with butter; so with tea and coffee, soap, etc. Now, contrast this way of doing with friend Terry's plan. When I congratulated his wife on the beautiful bread we had to go with the strawberries, he replied that they always had beautiful bread because they purchased flour only once a year. The quality was guaranteed; and when Mrs. Terry learned just how to make nice bread of that particular brand, she could do it *every time*. By the way, friend Terry has been recently writing some grand articles on this subject for our agricultural papers. Ask your wife what she thinks about it.

Now comes the great obstacle. I presume, friend C., you will say that it is all very well for Mr. Terry and other people who have money in the bank; but how in the world are poor people going to buy supplies by the quantity? My friend, it costs you very much more to buy in little dribs, aside from the higher price you are obliged to pay. Why, I have known farmers to say they had to go to town right in haying or harvesting, to get some sugar, tea, or molasses, or something of that sort. A little reflection should have convinced them that their time spent on the errand was worth more than the goods they brought home—yes, a good deal more. I have known a man to go on some foolish errand like this when he lost *five dollars* that might have been saved had he stayed at home and got in his hay and attended to his other crops.

Now, very likely many can not commence at once buying supplies to last a *year*; but, my friends, if you strain every nerve you can work toward it, and you will save money by so doing until you have a little surplus with which to buy in quantities. It takes *time* and *brains* and *care* to buy closely and to be sure that you are getting only a first-class article. Now, when you buy by the quantity, the time, brains, and care are needed only once, to be sure you get a low price and a first-class article. Then use it with economy and care, and make it go as far as possible. Do not, I beg of you, let an *ounce* of your nice flour or best grade of sugar or nice butter go into the swill-pail. Please pardon the expression, but I have felt constrained to use it because I have seen people who were poor, and who bought from hand to mouth, as the saying is, let more rich food go into the abovesaid pail than do people who have large property, and money in the bank. A great many people excuse themselves for buying in little dribs, by saying they make their purchases evenings, when their time is not worth any thing. It is a mistake. Everybody's time should be worth something evenings. He can educate and inform himself in a

thousand ways during his evenings to far better advantage than he can by loafing in the corner groceries.

Another thing comes in right here: The people who buy in little dribs almost always do the buying with a *pipe* in their mouths. They buy their tobacco and pipes in little dribs, just as they do their flour and sugar. Our shorthand writer says that tobacco is the second item of expense to our nation—far more than either sugar or flour. Now, I would stop buying piecemeal, even if it cost me such a sacrifice as going on short rations for a while. I would wear old clothes, and eat very cheap plain food until I could get money enough ahead to buy by the quantity. In regard to this matter of plain cheap food, I have a little story to tell you; but I think we will make it another article.

I have so far said nothing in regard to our catalogue prices. You notice we give the price on a single article, then on ten, and then on a hundred. Some time ago a young man came into our store and wanted some things to start a store himself. We agreed to let him have single articles at 10's rates. Well, I kept account of the time it cost to put these things up and ship them to him. It took a pretty smart clerk the best part of a day, and it amounted to only \$10.00. Our profit could not have been more than 50 or 75 cts., so we really *lost money*. Now, if he had taken \$10.00 worth of things in the regular way, half an hour would have been ample time for the whole transaction. And this is no exaggeration.

Many families waste valuable time and strength year after year in buying soap a bar at a time. Why, it is fearful. Dear reader, if you have been in the habit of doing that, stop it this minute. Ask your grocer how much lower he can sell you if you take it in lots of ten or a dozen, according to the way it is put up; or, better still, get his best figures on a whole box of just the right kind your wife likes best. Of course, she must keep a careful watch of the box of soap, and see that it is not wasted. If she is in the right sort of partnership with you in saving the pennies, she will do her part, I assure you. Have the right sort of soap-dish, and see that the children learn how to use this soap so as to make it go as far as possible, and yet give you all the benefit that soap *can* give. I am sure you can do it if you set right earnestly about it; and if you want to know just what Uncle Amos would recommend, it would be this: Just before you go to bed at night, you two, husband and wife, kneel down by the bedside and ask God's blessing on the project. Ask him to brighten and sharpen your intellects—give you wisdom and understanding in this matter of economy in the household; and you might also read that beautiful little text, "Who-soever hath, to him shall be given; and whosoever hath not, shall be taken even that which he seemeth to have."

ERNEST'S NOTES OF TRAVEL AMONG THE BEE-KEEPERS OF YORK STATE.

ON THE BICYCLE.

I left the reader at Mr. B. Van Wie's, and had just mounted the wheel. It was a beautiful morning, cool and bracing, and I felt in excellent trim for a day's wheeling. When we bicyclers start out for a day's run we at first experience a little weariness on the first two or three miles; and it seems as if it would be impossible to travel all day; but very soon the "second wind" comes on, as the wheelmen style it. I had just ridden far enough to wear off this first tired feeling, and to feel an exhilaration that comes after a five-mile ride. Yes, I felt as if I could go all day, and more too. The hills did not tire me, and the coasting down hill—oh, how lovely on that bright morning! I had gone about ten miles when I met a liveryman just coming down a big hill. I had ridden part way up it, and then dismounted. My face was, I suppose, somewhat flushed from the glow of the exercise; and the aforesaid man of horses, mistaking it for weariness and exhaustion, said, somewhat jeeringly, "Well, young man, I wouldn't travel across the country in that way for all the bicycles you can give me;" and with a crack of the whip he passed with a flourish, down the hill, as if he had said something very smart. I leisurely walked up the hill in the opposite direction; and on arriving at the top I again betook myself to the saddle for another delightful coast.

"No, old chap, I would not exchange *my* vehicle for your old rattlety-bang, for a good deal."

Noislessly I sped down the hill. The panorama of scenery; a deep valley here, and a hill on the other side; the winding and twisting of the road, a wayside spring, a little brooklet,—all of these added to the charm of that bicycle ride. Just ahead of me I noticed a man hitching up a light rig with two handsome bay horses. They seemed to be full of spirits. The owner, seeing me coming at a distance, I judge decided to let me catch up, or nearly so, and then thought he would run away from me. For a mile or two he did. I did not propose to make a fool of myself chasing after him. I stuck to my usual gate, and before long I came within a short distance of his tired and panting horses. He evidently regarded it as a race, by the way he kept looking back to see if I were catching up. I pretended not to so regard it. I saw his horses were beginning to lag; and when a favorable opportunity presented, that is, a clear piece of road—I very modestly asked him if I might have the privilege of passing, as I was in a hurry. "Oh! certainly," said he, and he turned his horses to one side, for I saw that he was quite willing that I should *believe* he was not trying to run a race with me. The road was a turnpike, and for the most part it was good wheeling. In a few minutes more my friend with his two horses was out of sight.

All along my route I inquired very diligently as to whether the road ahead had any sandy spots. The terror of all wheelmen is sand, and I should prefer to go four times as far around on clay rather than to attempt a short run over the sand. Just before reaching Middleburgh I struck a little piece of sand. Following along some paths along the road I managed to get along very well. In a few minutes more I was in Middleburgh, where I arrived about 11 o'clock. On inquiry I learned that Mr. Wesley Dibble and Mr. N. D. West, bee-men, whom Mr. Van Wie recommended me to call upon, lived a short distance out and directly upon my route. I asked a hotel clerk if I might

have a drink of water. He pointed to a water-tank outside of a bar. I hesitated somewhat; but being thirsty I took a small draught of water, without waiting to take any thing else.

I should remark right here, that, in making tours across the country, wheelmen, like horses, get thirsty; but we are obliged to be very careful and not drink too much water while in a sweat. I felt many times as if I should like to drink a whole quart; but I never took more than two or three mouthfuls; and after a while, on these limited rations of water every ten miles or so, the thirst would subside; and it is needless to say that I felt better for it. Temperance in all things—yes, even with water—is advisable and prudent. Well, I mounted the wheel, and in a few moments more a bee-keeper's home was pointed out to me—that of Mr. Wesley Dibble. I wheeled up alongside of the house, dismounted, and inquired if that was the place where Mr. D. lived. An affirmative answer came from the gentleman himself. The pump had gotten out of order; and the water being low, he had withdrawn it; and, having repaired it, he was about to put it back in. I arrived in time to help him put it down, when he conducted me to the apiary in the rear of the house. It was a very pretty yard, and contained 70 or 80 eight-frame hives, of a pattern almost identical with the Dovetailed hive. Like all other progressive bee-keepers of this section he used fixed frames. If I remember correctly they were closed-end, and suspended, something like Mr. Tunnicliff's that I explained on page 641. Two or three years ago he bought 50 Heddon hives, but he has discarded them all now. I might say in this connection, that I heard of another bee-keeper who had purchased some 45, and had likewise discarded them. Both averred that it was too much trouble to handle so many frames, and they finally went back to the regular Langstroth.

AUTOMATIC SWARMING A SUCCESS.

But what interested me particularly at Mr. Dibble's was his automatic swarming-arrangement. It was his own invention, having conceived the idea some two or three years ago. During the past season he has been using it successfully in his two out-apiaries. A colony that he thinks is about to swarm is fixed with perforated zinc tubes, and an empty twin hive is set beside it. When the swarm issues, the queen passes along the tin tube into the empty hive where the returning swarm meets her, settles down, and builds up a new home. The plan works so successfully with Mr. Dibble that he always swarms bees in this way, and is enabled to dispense with the services of a man in each yard, or a bounty of 25 or 50 cents for each swarm hived.

"Why," said I, "your arrangement is very similar to Mr. Alley's."

"Yes, it is similar," said he; "but it is my own invention, and I had been working along this line a year or two before Mr. Alley or Mr. F. D. Lacey made their inventions public."

The ever-ready Kodak was pulled out, and I took several views of the swarming-arrangement, and also of a handy tool-house for bee-keepers. Both of these I will illustrate and describe more minutely later, when the engravings are made.

Mr. Dibble is considerable of a genius. He has constructed a horse-power and hive-making machinery, whereby he makes all his appliances. That he is a good mechanic, is evidenced by his fine work. After taking dinner with my friend I buckled on the Kodak, oiled up, and betook myself to the road again. Mr. N. D. West, owning some 400 colonies, lived a couple of miles beyond. A short spin of a few min-

utes, and I arrived at the place. I tied my horse up beside the fence, dismounted, and rapped at the door. I was not quite so fortunate this time as I had been on former occasions. Mr. West himself was absent, but fortunately I met his son, who evidently was a good bee-keeper. I was in a great hurry to see all I could, and I explained to the junior West that I had to make some miles yet, and would have to hurry at his place more than I really preferred; I might strike some bad roads, and needed plenty of time. We immediately went out into the apiary. Here, again, fixed distances are used. Some of the frames are the Hoffman, and others are the regular suspended, with nails driven in the right distance, to hold them at fixed distances. They have in all 400 colonies in three yards. The season had been a poor one, but they would average about 25 lbs. per colony. We soon repaired to the shop, where I noticed a similar horse-power to that used by Mr. Dibble. My stay here was probably not more than 15 or 20 minutes; and after apologizing for my short visit I again took to the wheel.

HOW I RAN AWAY FROM A BEE-KEEPER.

Being in company the night before with a lot of roughs in the hotel at —, as mentioned in the previous number, I presume that I was a little bit nervous. I came along to a stretch of road where there was a sort of sidehill. It was down in a kind of valley, and quite remote from any farmhouse—possibly a mile either way. I saw a man going along the road, with a walking-stick. "Now," thought I, "may be he is all right, and doubtless won't do any thing out of the way, but I will just steal upon him rather quietly." As the bicycle is perfectly noiseless, when I get just about opposite to him I will spin by him before he knows it;" and this was almost immediately put into execution. After I had got a little distance beyond, I thought I heard him calling to me. Whether I did or not, I hustled up the hill as fast as I could. On arriving at the top I coasted down the hill at the rate of about a mile in four minutes; and as I was speeding down as if on wings, I congratulated myself on how *nicely* I had fooled the personage whom I had met in the valley back of me. I finally came to a farmhouse, and mentioned the little circumstance.

"Oh, no!" said the farmer; "we are all honest men down this way."

"That may be," said I; "but if you had been traveling over the country as I have been, alone, you would not be disposed to trust every man, especially when you are off alone a mile or two from any farmhouse."

At this point I can not forbear giving you the sequel. I do not know whether it is a joke on myself or on my friend, but it is rather on me. Just read this extract from a business letter:

EXTRACT FROM A BUSINESS LETTER.

Mr. N. D. West stopped at my house to-day. He told me that Ernest Root was at his house on the 13th, and that he passed through this place on his way to Durham. Well, I saw him a short distance off. If he remembers, just before he reached this place, on the right, below the road, a level piece of land, swamp, and meadow. I was down there looking to see what the honey prospects were from the golden-rod and boneset. I saw some one pass along the road on a bicycle, as if the "old boy" was after him, so I hurried up the bank and after him, just in time to see him going over the hill, nearly out of sight. If I had known it was Ernest, I should have overhauled him. I think I could have done it, as he had quite a hill to go up. I am very sorry that he could not stop and see me. I hope he will if he ever comes this way again.

BEN FRANKLIN.

Franklinton, N. Y., Aug. 21.

Well, well! a bee-keeper and an honest man! and I, a doubter of a fellow-being! After arriv-

ing home I was told that there was a letter from a man who saw me going through the country, but was not able to overhual me. I did not say any thing, but I began to suspect that I had made a fool of myself; and the writer of the above, I have no doubt, was the very individual who would have given me a nice bee-talk, and told me about his bees. Well, I hope he will forgive me; but who in the world would have thought that there was a bee-keeper who knew me, in that lone valley? and when he would stop me for a friendly chat, I just ran away! Well, I wended my way on my journey, entirely oblivious to the fact that I had run off and left one of my bee-keeping friends.

A RACE WITH A HORSE.

I finally came to a toll-gate. I stopped and inquired the toll. "Oh!" said the good-natured toll-keeper, looking at me and my wheel, "we hardly regard your rig as worth considering. You may pass on," said he, waving his hand. I did not know whether to feel pleased or not. At any rate, another rig, just behind me, came up, and the driver paid his toll. He had a race horse and a sulky; and from the former experience I had had, I knew that he wanted to see whether that fellow with a wheel could keep up with him. I put on all speed, but endeavored to *appear* as if I were not racing, but simply taking my ordinary gate, you know. I managed to monopolize the whole road, so that it was a difficult matter for him to pass, even if he would. There were farmhouses all along this road, and I rather enjoyed the fun. We ran together for perhaps two miles, and I was beginning to feel as if I had got tired of racing—at least, running at such a rate of speed—when I observed that the panting of the horse behind me was growing fainter and fainter, and finally, in a few minutes more, the driver and the horse were nowhere to be seen. The fellow *could* have gone by me, I know; and I am equally sure that, after a run of five miles, the wheel would have been a long distance ahead. I do not speak of this because I have any superior skill or endurance as a cyclist, but only to show what a mediocre rider like myself has done many a time. A good horse will outstrip a bicyclist for a short distance; but they are away behind on a long run.

Yes, sir; a Victor bicycle is worth regarding, the toll-keeper to the contrary; and while I am not *anxious* to pay toll, I like to have that most delightful of all steeds, the Safety bicycle, at least put on a par with the best of horses, both for speed and endurance for long runs; but to prove that parity, I hardly think I shall agree to race with every horse-jockey.

After stopping on the way for a refreshing drink I again started, and in an hour or two more I saw the spires of Durham. How my heart leaped at the sight! I had not seen my wife for a *couple of weeks*, and that was an awful long while for me; and I felt that my feelings duplicated hers. On arriving at Durham I was informed that Shady Glen—the place where she was stopping—was about three miles out. Over a winding and somewhat hilly road I traveled until the welcome sign, "Shady Glen," pointed to the place. In I came, with a flourish. It was then only three o'clock. I had gone 45 miles that day, visited the bee-keepers on the way, seen some beautiful country, and all before three o'clock. Mrs. Root was on Mount Pisgah, with a party of tourists, and would not be back till night; but a little niece recognized me among the first; and finally I met her papa and mamma. I was asked if I was tired. No, not at all. I was ready for a romp down the glen, and away we went.

[To be continued.]

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

That art on which a thousand millions of men are dependent for their sustenance, and two hundred millions of men expend their daily toil, must be the most important of all—the parent and precursor of all other arts. In every country, then, and at every period, the investigation of the principles on which the rational practice of this art is founded ought to have commanded the principal attention of the greatest minds.

JAMES F. W. JOHNSTON.

RAISING FEWER KINDS OF VEGETABLES; E. C. GREEN, OF THE OHIO EXPERIMENT STATION, DISCUSSES THE MATTER.

Mr. Root:—Your idea of making your catalogue of seeds contain only one or two kinds of the best, struck me so favorably that I have added my mite. After being here at the station in the garden for two years, and testing varieties of vegetables by the wholesale, as one might say, this idea struck me as a most sensible one, especially so when coming from a seedsman. To give an idea of the seeds we test, this year our list is something like this:

Potatoes, about 90 kinds; onions, 40; sweet corn, 40; tomatoes, 50; celery, 50; cabbage, late, 40; early, 20; and so on through the list of vegetables, to say nothing of small fruits. We have been trying to cut our list down to include the standard of the old kinds and the newer varieties.

In lettuce we have made three tests during the past year—two in the greenhouse and one in the field, which included about 90 so-called sorts each time. I say “so-called” sorts, for it is not at all strange to find one kind with several names; and it sometimes happens that a seedsman will send out the same kind of vegetable under two names. Taking, for example, lettuce, I found, out of the 90 so-called varieties, they could be divided into about twelve classes, each class containing from two to eight varieties. Thus, in one class would be put the Grand Rapids, Black-seeded Simpson, and White-seeded Simpson, and others of this class.

But after seeing all these kinds growing, I can say that there seems to be one or two in each class that contain the best points; and, taking this with the fact that about two-thirds of the classes are not worth raising, it cuts the list down to a very few kinds; and when we get it down to a few there are still some that are the best for particular markets and uses.

To cut down a list is quite easy work until we get to the last three or four, and then comes the trouble unless we know just what the market or use they are put to calls for. For example, does your market call for a bush lettuce, then give them the Black-seeded Simpson or Grand Rapids; if they want a head lettuce, then the Deacon is good; or one for table decoration, then the Boston Fine Curled. What is true of lettuce applies to nearly all vegetables; the different kinds and sorts are mostly made by the seedsmen in order to have a novelty to introduce. Still, there is something new brought nearly every year that is valuable; but to find them among so many that are worthless is a costly task; and, on the whole, it is nearly always more satisfactory to have one or two kinds that do well than so many failures.

Columbus, O., Oct. 6.

E. C. GREEN.

Friend G., “a friend in need is a friend indeed;” and you have come to my aid most opportunely. Why, with the experience you have just been having you can do us an immense service. A brief article from you—say a single page in GLEANINGS—will probably save our readers alone thousands of dollars, especially if

they profit by it. Now, to start the ball rolling I will briefly map out what I have been proposing for the next year. In the following list, where I mention only one vegetable it will be understood that we have decided we need only one kind. After I get through I want your amendments and criticisms at length. Very likely you will double or treble my list. But that is all right. I want you to do so if the best interests of the people demand it. Now, here goes:

Asparagus—Henderson’s Palmetto.

Bush beans—Henderson’s Bush Lima; Kidney Wax; White Kidney.

Pole Beans—King of the Garden lima.

I am not sure that the King of the Garden lima is very much larger than selected beans from the ordinary lima; and you will notice that I have dropped the Extra Early lima. I have done so, because a great many seasons they are little if any earlier than the King of the Garden.

Beets—Eclipse; Lane’s Improved Sugar; Long Red Mangel.

Cabbage—(I tell you, friends, it is a hard matter here. I have decided not to recommend more than four kinds; but in selecting the four I felt a good deal troubled; but here goes for an attempt.) Jersey Wakefield; Excelsior Flat Dutch; Perfection Drumhead Savoy; Large Red Drumhead.

Carrots—Orange Danvers.

Cauliflower—Early Snowball.

Celery—White Plume; Golden Dwarf; New Rose.

Sweet corn—Corey’s Extra Early; Late Mammoth.

Cucumber—Early Frame; White Spine.

Lettuce—Grand Rapids; Boston Market; Henderson’s New York.

Muskmelons—Landreth’s Extra Early; Emerald Gem; Banana.

Watermelons—Landreth’s Extra Early, and—after all the kinds I have planted and tested, I am not really satisfied to give any single one the preference. Friend Green, please supply one besides the Extra Early.

Onion—Silver Skin; Globe Danvers. For a large foreign onion, started in the greenhouse, I would suggest White Victoria, although I am not sure that it is any better or much if any different from the Silver Skin; for a winter onion, Winter or Egyptian onion-sets.

Parsnip—I do not know which kind is best. I am not sure there is much difference.

Parsley—Double Curl.

Peas—Alaska; American Wonder; Strata-gem.

Peppers—Bullnose; Cayenne.

Potatoes—Now, right here I can not really decide whether we want both Early Ohio and Early Puritan or not; and if we want only one, I am afraid to put either in place of the other. For late I would have Lee’s Favorite; and for a

very late potato, Terry's preference, which he calls the Monroe Seedling.

Pumpkins—For the market-gardener, Early Sugar.

Rhubarb—I do not know which is best—Victoria or Linnaeus.

Radishes—Vick's Early Scarlet Globe; Wood's Early Frame; Beckert's Chartier; Chinese Rose. This list is rather long; but as each is particularly suited for some special season, I do not know how we can avoid having so many.

Salsify—New Mammoth.

Spinach—Bloomsdale Curled.

Squashes—Giant Summer Crookneck, and Hubbard for a winter squash. I have become disgusted in trying the much-lauded new squashes, and finding, after all, that none were equal to the old genuine Hubbard. The Hubbard not only sells better than any thing else, but with heavily manured and early worked ground it yields about as many tons per acre.

Tomato—Ignotum. I should rather like to have the Golden Queen, and possibly some Peach tomatoes and Pear-shaped, just for the fun of it; but for actual profit I do not believe it pays. We have for years carried the Pear-shaped tomatoes on the wagon until they became so bruised they were worthless. Once in a while somebody wants them; but the demand is too small in our town to pay for carrying them around.

Turnips—Purple Top White Globe, and some sort of French or Swede turnip. For three or four years past we have not found one that suits us. When I was a boy my father used to raise them as big as a peck measure, and they were sweet and tender when cooked. We have not succeeded in getting any like them during the past ten years. I wish somebody would tell me whether the fault was in the seed or location. Father raised them on sandy, gravelly soil. We have tried them here in Medina in all kinds of ground.

Now, friends, after friend Green, has given his opinion and advice I want you all to pitch in and help. I am going to have a seed-catalogue before the first of January, all on one page, even if it costs hundreds of dollars to get it down on one page. It may need to be amended more or less every year; but my present notion is, that it must be kept down to about the number of varieties I have outlined above.

TERRY'S METHOD OF GETTING AN EVEN STAND OF STRAWBERRIES, NEITHER TOO THICK NOR TOO THIN.

Friend Root:—We are thinning out our strawberries now, and I was just reading what you say on page 720. Probably friend Pierce and myself are both right for our different circumstances. He makes a business of growing small fruits, and says he kept a man in his berry-field all through August, and September, perhaps, to train the runners and let only enough grow to make a proper stand. He further says, a weed is a plant out of place, and asks, in the *Country Gentleman*, why I let them grow and occupy the

ground, to be taken out and thrown away afterward.

I am a farmer. In August and September our time is very valuable at our regular work. If I had the berries carefully watched during that time, and only those plants that were needed were allowed to take root, I should have to hire extra help to do it. Now our hurry is over, and my man can do it at no cost, as there is nothing else that needs attention.

When the runners were well started we went through once and placed them around, and then let them grow unmolested. The stand is almost perfect. I wish I could send you a photograph. It is natural for strawberry-vines to grow and run and multiply freely, and I believe they are the most healthy and productive when allowed to do so. But to make the fruit large we must thin them out after they get about through. Again, I would rather do this all at once, now, than to go over and over the patch for months. With a garden-trowel, ground sharp, we find we can, with a single push, cut the plants off just at the bottom of the crowns, and take them out very rapidly, without making any hole or disturbing the others. As they have been running since the last of June they will hardly do any more of this, and the thinned-out plants can now grow and get a good ready for business next year.

We have cut our rows down to paths 16 inches wide, and beds 32, with plants as nearly 6 inches apart every way as possible. I do not think as many bushels to the acre of as fine large berries can be grown practically in any other way. There are other plans that will grow as large fruit, but not, I think, as many bushels.

When destroying the small feeble plants, and the large ones where they were too thick, last year, we left them in the paths and some in the bed. It wasn't a finished nor a satisfactory job. This year we put them in baskets and remove them. The plants are held to each other by the runners, so it is not easy to get them out, except by cutting these off. If the side of the trowel is ground sharp we find it will cut them readily.

Hudson, O., Oct. 4, 1890.

T. B. TERRY.

Friend T., we know by experience that there is wisdom in what you say. We have gone over our plants three and perhaps four times with some of them, where they were set in July, and it is a pretty big job. I feel quite certain that your plan would be the best economy of labor, and perhaps the economy of labor would make up for what would be gained in not having the ground at any time overcrowded. It is a question in regard to the help that may be available. As I have already said, it takes a person of skill and experience to do the work nicely. Boys, as a rule, will take a great amount of time, and not get just what you want even then, unless they are, say, toward 18 or 20. I heartily agree with you in regard to putting the refuse plants and weeds in a basket. With a little practice, our children will pull weeds and put them into a basket about as quickly as to throw them on the ground; and if they are in the habit of giving each weed a fling, there will be a saving of time by putting them into the basket. Then your work is clean and well done, and your path looks slicked up; whereas if the weeds are thrown in the paths, when a heavy rain follows a great many will grow. I have just had a most interesting and pleasant visit from two of our

leading strawberry-men — Matthew Crawford, of Cuyahoga Falls, and Mr. Little, of Canada. Mr. Little is the gentleman mentioned in the strawberry book as the one who got well in spite of the predictions of the doctors. Getting interested in strawberries is what cured him.

Friend Crawford and myself, and others who sell strawberry-plants, can make use of these little plants where they get in thickly, especially where the variety is a valuable one. Put them in the plant-beds 6 inches apart; and when they grow big and strong, use them to fill orders. Friend Crawford, this season, succeeded in getting splendid strong plants by using the sets before they had made even a single root. He did it, briefly, as follows: Cover your rich plant-beds with clean sand to the depth of an inch. Put the sets down in the sand, say two or three inches apart. Keep the sand constantly wet, as florists do for cuttings, and cover the bed with a cloth frame until the cuttings are rooted. You can put them down quite deep in the pure sand, and the new leaves will make their way up through it. The new roots will push out into the sand readily, and when they get down into the very rich plant-bed soil they will grow amazingly. I wish I could tell you how we three strawberry enthusiasts enjoyed the walk over our grounds. And there was another tie that bound us together. We could all heartily unite in outspoken thanks to Him who gave us not only the strawberry-plant, but all these other wonderful gifts.

PETER HENDERSON'S PLAN OF RAISING STRAWBERRIES.

Can you explain why Peter Henderson speaks confidently of his method of planting potted strawberry-plants in July and getting a full crop the year following, and then planting the ground to some late crop? With him this seems to be no experiment, but rather a common practice. Now, most growers differ with him in practice, and agree with Mr. Terry; viz., spring planting. Which is better? Again, would the Sharpless or Parker Earle do as well as the Jessie to fertilize the Haverland?

Kingston, Pa., Sept. 30, 1890.

M. G.

Friend G., I suppose there is no question but that spring planting will give a larger crop than planting in July, even with potted plants; but with Peter Henderson's ground, with its great fertility, in consequence of heavy manuring, no doubt he could do wonders with strawberries. I do not believe, however, that he ever raised very many strawberries on that plan. I have visited his grounds at two different times, and all I could find was a small plot devoted to raising potted plants.—The Sharpless will not answer as a fertilizer as well as the Jessie, because it does not produce so large an amount of bloom, both early and late. The Parker Earle is now growing finely on our grounds, but we have never yet fruited it.

THE OREGON EVERBEARING STRAWBERRY.

As we have received several hundred letters from our advertisement in GLEANINGS, asking

about the Everbearing strawberry, we will answer them all through GLEANINGS. We have no more plants to sell, but will send a few to those who wish to test them, and will report how they succeed. With us the berry has done wonderfully. We purchased 150 plants of Mr. Winquist last year. A few were set on poor clay soil, and the remainder on very rich soil. Those set on clay soil have borne profusely all summer, and are at this date laden with berries; but those set on rich soil did not bear so profusely, but have made many sets, while those on clay soil have made no sets. We believe the berry will be a success if planted on clay for berries and on rich soil for sets.

J. B. ALEXANDER & Co.

Hartford City, Ind., Sept. 22, 1890.

Well, friends, GLEANINGS proved to be a very good medium to advertise in, in this case, it seems to me. We are sorry to say, however, that our Everbearing strawberries from Oregon do not seem to be very thrifty, and at the same time are in very rich ground. While in our plant-beds in the spring, they were sending out runners about as rapidly as any of our plants; but in order to make room for our new building, they had to be removed; and although they were carefully transferred with transplanting-tubes, they have acted sort o' contrary ever since. Some of them are, however, putting out runners fairly, but no fruit.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

QUESTION 170. *On the average, which will do a better season's work—a colony of pure Italians or one of hybrids?*

We prefer the Italians.

Illinois. N. W. C.

MRS. L. HARRISON.

My experience favors the hybrids.

California. S.

R. WILKIN.

I don't know. I prefer the Italians.

Illinois. N. C.

J. A. GREEN.

After testing the matter *thoroughly* we prefer pure Italians.

Illinois. N. W.

DADANT & SON.

I have not had a colony of pure Italians for a number of years.

Ohio. N. W.

E. E. HASTY.

I don't notice any difference. I have colonies of hybrids that are far ahead of some of my Italians, and *vice versa*.

Ohio. N. W.

A. B. MASON.

Italians, for white honey. In some localities where much fall honey is secured, hybrids might do as well or better.

Vermont. N. W.

A. E. MANUM.

Hybrids, in this locality. In some places pure Italians are better. Many hybrids are called pure by their owners.

New York. C.

P. H. ELWOOD.

I don't know; but I believe there is more in the way bees are managed than there is in the breed or race.

Wisconsin. S. W.

E. FRANCE.

This depends. I think no invariable rule can be given. It depends much on the individual character of the colonies.

Michigan. C.

A. J. COOK.

There was a time when I thought that hybrids were the best honey-gatherers; but I have changed my mind. I believe that the Italians are the most profitable bees.

Ohio. S. W.

C. F. MUTH.

Doctors disagree. I got severely bounced once for giving my opinion upon this delicate question; and now, if you please, I'd rather not say.

Ohio. N. W.

H. R. BOARDMAN.

There is little difference in a good season; but in a medium to poor season the Italians are very much preferable. Then we must have the Italians to get a hybrid Italian, you know.

New York. C.

G. M. DOOLITTLE.

I am sorry to say I know nothing about it from actual observation. Reasoning from analogy, I should think it possible we might expect more vigor in a first cross than in a pure race.

Illinois. N.

C. C. MILLER.

The querist speaks just as though hybrids were hybrids, and all just alike. I will say that the right kind of hybrids from the right races of bees, and the right strain of these right races, will do a better business than any pure Italians. That is my experience.

Michigan. S. W.

JAMES HEDDON.

It might be a little hard to determine. For extracted honey we prefer the Italians. They are nearly moth-proof, and defend their hives well from robbers. The first cross from pure Italians and blacks generally produces bees that are hard to beat as honey-gatherers; but it is difficult to keep just that grade, hence we prefer Italians.

Wisconsin. S. W.

S. I. FREEBORN.

Our preference is for the hybrids. Our best out-apiary had very good Italians. The young queens met black drones, which were plentiful in the neighborhood. The cross caused the bees to become very industrious with their stings, and we have been compelled, not by threatenings of law proceedings, but out of courtesy for the feelings of others, to move the apiary to a less exposed position, some 20 rods from any habitable building. These bees were tearers for gathering honey. They beat the record of all my other apiaries.

New York. E.

RAMBLER.

Well, friends, I am astonished, and I don't know but I might say I am a little bit disgusted, to see that so many of you intimate that there is not "very much difference." Friend Doolittle hits the point I have in mind. If it were not for the *Italians*, you would not have even any hybrids. And now, friends, if I may disagree with so many good men, I can hardly believe there is one of you who would keep on bee-keeping with any thing like his present energy and enthusiasm if your future operations were to be confined strictly to black bees and nothing else. Friend France was pretty positive when I was there, and I am glad to know that he has changed enough to say just now, "I don't know." If I am not mistaken, he once told me that he would just as soon, or a little rather, have the "simon-pure" blacks." Very likely they would

be more peaceable, for some of his hybrids were veritable little tigers; and I don't know, by the way, but that it is getting to be a little fashionable to have this sort. Ernest found them with most of the big bee-keepers in York State. Now, I hardly believe they have a preference for such bees; but my opinion is, that it takes so much time to keep the Italians pure they just let them slide; and then, rather than admit this state of affairs, they defend the hybrids. Yes, I know that hybrids gather honey; and I should not be surprised if, taking seasons as they come and go, hybrids, as a rule, would get just as much as pure Italians.

THE INTERNATIONAL AMERICAN BEE-ASSOCIATION.

FULL PARTICULARS, ETC.

Friend Root:—Inclosed find the programme of the I. A. B. A. for the Keokuk meeting. I wish to add to it, that the Business Men's Association of Keokuk have voted to pay for the rent of the commodious G. A. R. Hall out of their own fund, for the use of the bee-men. Thanks will be duly extended to them at the proper time for this generous action.

In regard to the questions to which you call my attention in GLEANINGS for Oct. 1st, I will say that I had already offered some of our own honey to the hotels in question, and had made sure of their having a supply on hand for the use of our bee-men; but to give our members a chance to taste different kinds, as you suggest, I have made another plan, and here it is:

A number of those who have expressed their intention of being present at the meeting have also stated that they would like to visit our establishment. As we are located nearly five miles from the place of meeting, it would be difficult for any one to attend all the sessions and come here at the same time, and I have thought of proposing to the convention to hold the last session at our establishment. We have lately built a new bee and honey house, 20 x 32, which is not yet occupied, and would do for a dining-room, and Mrs. Dadant, Jr., feels equal to preparing, with a little help, one meal for the fraternity of the I. A. B. A. So we might adjourn at 11 A. M. of the last day, and call up the closing meeting at Hamilton, after dinner. At this dinner we shall have a good chance of giving our bee-men a taste of all kinds of honey or honey-cakes which may be brought; and since you have made the first mention of this, I now call upon you to bring us sufficient samples of all that you can procure, or that your readers may wish to bring or send for the occasion. I will see to having the reporters on hand, and to treating them well.

I also propose to start a subscription to offer a premium of, say, \$20.00 for the most palatable dish of any kind—cake, pie, preserves, etc., prepared with honey, said dish to be tested by competent judges at this meeting, and the manner of preparing this dish to be published in GLEANINGS subsequently.

Allow me also to state, that all goods sent for exhibition will be transported to the exhibition room free of charge, if *prepaid to Keokuk*, and addressed to me. I hope our dealers and manufacturers will avail themselves of this offer, and do all they can to make a notable display.

Hamilton, Ill., Oct. 8.

C. P. DADANT.

The following is the programme:

FIRST DAY.—WEDNESDAY, OCTOBER 29.

- 9 A. M.—Call to order. Reception of new members. Payment of dues. Appointment of committees for question-box and other purposes.

- 10.—Address of Welcome.—J. E. Craig, Mayor of Keokuk.

Recess.

- 11.—“Fifty Years’ Progress in Apiculture.”—Thos. G. Newman, Editor American Bee Journal, Chicago.

Question-box.

- 1:30 P. M.—“Apicultural Journalism.”—W. Z. Hutchinson, Editor of The Bee-Keepers’ Review, Flint, Mich.

Discussion.

- 3.—President’s Address.—Hon. R. L. Taylor, Lapeer, Mich.

- 3:30.—“Honey Pasturage of the U. S.”—A. I. Root, Editor of Gleanings in Bee Culture, Medina, O.

Discussion.

Question-box.

- 7.—“Apiarian Exhibit at the coming Chicago International Fair.”—Dr. A. B. Mason, Auburndale, Ohio.

Discussion.

Question-box.

SECOND DAY.—THURSDAY, OCTOBER 30.

- 8:30 A. M.—“What I Don’t Know about Bee-keeping.”—C. C. Miller, Marengo, Ill.

Discussion.

- 11.—Condensed reports of the Affiliated Associations in regard to crops and prospects.

Question-box.

- 1:30 P. M.—“Is It Best to Use Full Sheets of Foundation in Brood and Surplus Combs?”—Eugene Secor, Forest City, Ia.

Discussion.

- 3.—“Fixed Frames versus Suspended Frames.”—Ernest R. Root, Medina, Ohio.

Discussion.

- 7.—“The Conditions Necessary to Insure a Honey Crop.”—Prof. A. J. Cook, Agricultural College, Mich.

Discussion.

Question-box.

THIRD DAY.—FRIDAY, OCTOBER 31.

- 8:30 A. M.—Business of the Association. Report of Secretary and Treasurer. Election of officers.

- 11.—“In an Apiary Run for Honey only, are Italians or Hybrids Preferable?”—C. F. Muth, Cincinnati, Ohio.

- 1:30 P. M.—Volunteer contributions from different sources.

- 3.—“The International Bee-Association; Its Past and Future.”—W. F. Clarke, Guelph, Ont., Can.

The question-box committee will receive questions at any time, and will appoint different members to answer those that are deemed of sufficient interest or importance.

As this is the first meeting of this International Bee-Association west of the Mississippi, it is hoped that the Western bee-keepers will make an effort to show what the West can do. A number of ladies are expected as usual. The essayists named in the programme will nearly all be present.

A special room on the same floor as the G. A. R. Hall has been secured for exhibits of bees or their products, or implements, and a special committee will report as to their merits.

The Hotel Keokuk, one of the best hotels in the West, a \$3.00 house, will take members at \$2.00 per day. The McCarty Boarding, in Estes House, on the same floor as the G. A. R. Hall, will board members at \$1.00 per day.

Reduced railroad fares have been promised; but at the printing of this programme nothing definite has been given.

Parties wishing to attend will be freely furnished all necessary information and reduced rates if same are to be had.

C. P. DADANT, Sec’y.

OUR HOMES.

Give, and it shall be given unto you; good measure, pressed down, and shaken together, and running over, shall men give into your bosom. For with the same measure that ye mete withal it shall be measured to you again.—LUKE 6:38.

Some of you may perhaps say that I have had the same text before, or, at least, a part of it; and I confess that the truth contained in this one verse from Luke is one that I have considered and talked upon over and over, and I don’t know but that I shall continue to talk upon it to the last day of my life. A few days ago the pastor of one of our churches asked me to talk to his people Sunday evening on business and religion—their relations to each other. The congregation was not very large, but it comprised my warm personal friends. Just before I commenced, the pastor whispered to me that the greater part of my own helpers in the factory and on the grounds were among the audience. He said it spoke well for me. I felt it, and I feel glad now when I think of it, that those I meet day by day are, at least the greater portion, warm personal friends. I told them that my first experiments in combining business and religion commenced with my conversion. It was in that same church where I was speaking between fifteen and sixteen years ago, that I announced to those gathered during a union meeting something like this. Said I:

“Dear friends, I have all my life been a busy man, and I propose to be a busy man still; but hereafter, God helping me, it shall be Christ Jesus first, and self second.”

I did not realize how much that public promise and pledge included. But my dear Savior made it known to me what my enlistment meant, right off. When I opened up business next morning, I remembered that there had been a great deal of strife between myself and my next-door neighbor—a jeweler—as to who should sell things cheapest. We were each of us doing a comparatively small business. A silver-plated teaset was a pretty large thing for Medina just then; but we had both invested to the full extent of fifteen or twenty dollars, and a lady had been going back and forth from one store to the other to see who would sell lowest.

She came into my store that very morning, and said she thought she would take the one belonging to my neighbor, unless I could come down a little more in the price. I told her I had decided not to offer it any cheaper; in fact, I had made up my mind to let my brother in trade make the sale. She seemed right away to gain confidence in me, and began to ask my advice something as follows:

“Mr. Root, do you really believe that his set is just as good quality as your own?”

This question was a stunner. A week before, I should have assured her that it could not compare with the old established brand of — & —. I thought a minute before replying. I knew the reputation of his plated ware very well, and tried to put myself outside of business while I answered truthfully before the Savior whom I had promised to honor and serve. I told her, finally, that I felt quite sure that his was good—probably there was but very little difference. Then she remarked that the other man told her that he *bought* cheaper than I did, and that was the reason why he could sell lower. She asked if I thought this was true. What should a follower of Christ Jesus answer? I told her pleasantly that I paid prompt cash, and that I thought I got goods very low; but I added that it was still possible that he did buy a little lower than I did. Now came the last trying question:

"Mr. Root, I have bothered you a great deal already, and I feel a little bit ashamed for having made you so much trouble. I hope you will not think unkindly, but I think I should prefer the other set at the price."

By this time I had so far overcome self that I made up my mind that I would finish up the transaction for Christ Jesus, even if the goods did remain on my hands. I answered promptly something as follows:

"Why, my good friend, we are both anxious to sell, and I confess I rather need the money; but my friend — has not been as long in business as I have, and I suppose he needs the trade more than I do. What is my loss will be his gain, and on the whole I shall feel quite well satisfied to have him make the sale."

I put the teaset back in its glass case, and my customer went away. For several days I lost the sale of article after article, turning the trade right over to him. But a new peace and joy had begun to fill my soul. There were times when I felt a little doubt about the outcome; but it was not long. Pretty soon my rival in business came down to inquire what had happened. Perhaps I should tell you, that, for weeks or months before, we had been assailing each other through our county paper. Both of us bragged of our acuteness, and spoke sneeringly of the other. The change was so sudden, however, on my part, that it startled folks just a little. When he came down to see me he was changed too. Said he, "Mr. Root, if this is religion, I, too, want to be a Christian."

Is it any thing surprising, dear friends? It was not many days before it was my pleasure to kneel with him in prayer, and to hear him ask the dear Savior for mercy and pardon. Our relations from that time to this have always been pleasant. How could they be otherwise?

Now for the other part of the transaction. Did I really lose? Why, bless your heart, no. From the moment I took that stand, and began to make the little text at the head of our chapter my motto in life, my whole life was changed. I not only rose up out of the miry clay in spiritual matters, but it was the same in business. Please, now, do not think that I wish to exalt A. I. Root in what I am going to say, for you who have known me long and known me better will believe me when I say that I wish Christ Jesus, whom I try to serve, to have the glory and honor, and by no manner of means my poor self. Well, this is what I want to say: From the moment I stopped this little petty quarreling over who should be first, or who should have the trade, my reputation as a business man began to extend over a wider field. Every thing grew and prospered on my hands. God seemed pleased to verify his many promises in blessing all my undertakings.

In times past I have told you about answers to prayer, in the line of pecuniary matters. Don't imagine that, because I have ceased to speak of these things, such experiences come no more. I have thought best not to speak of them, because there is great danger of being misunderstood. But I want to speak of one right here. When I began giving employment to women and children who were left destitute of husband or parents, a great many times I undertook to give more work than I had work for them to do. In this dilemma I prayed that God would sharpen my business perceptions and abilities. I prayed, too, that he would send me the money, or tell me how I could get it. Let me tell you of one marked answer to such prayers. A hundred-dollar bill came in a plain envelope—no scrap of writing with it. It came just after I had been asking God for means. I was startled somewhat, but I told the clerk who opened the mails that somebody had sent it in

a hurry, and that the order would probably come in the next mail. The next mail, however, did not bring any order, nor did it come for a week or two. It began to look very strange and unaccountable. Finally one of the good bee-friends wrote something like this:

"By the way, Mr. Root, I suppose you got that hundred-dollar bill I mailed you some days ago. I took it in a trade, when I was away from home, and I did not want to carry it around with me, so I just put it in an envelope and mailed it to you. I wanted it somewhere where it would be safe, and I knew that, if it got into A. I. Root's hands, it would be all right until I called for it."

There, friends, is a lesson for you. In holding fast to the Bible promise in carrying out my queer ways and fashions, as some called them, I was unconsciously laying the foundation of the great business that has been built up around me. Some called it a sharp trick of mine to advertise. Dear friends, it was no sharp trick at all. I had no idea of the outcome. My course of action sprang from a simple, honest determination to serve Christ Jesus by letting him come first, and self second. My experience has only verified the beautiful little text where Christ says, "Then shall the righteous answer him, saying, Lord, when saw we thee a hungered, and gave thee no meat? or thirsty, and gave thee no drink?" It was just so in my case. I built up a reputation without knowing it. Now, friends, you can do the same thing. If you are constantly straining every nerve and faculty for *self*, you will miserably and utterly fail. If, however, you are constantly and honestly seeking to put down self and exalt Christ Jesus, even in business matters, then shall you be built up. The above, you see, is put in my own words. Read how Jesus put the same thought about being exalted: "For whosoever will save his life shall lose it; but whosoever shall lose his life, for my sake and the gospel's, shall save it."

Perhaps some one may say, "Then there was no answer to prayer about it. The money came because this friend had confidence in you, and not because of your prayer." Not so, my good friend. God heard the prayer, and answered it, but he would not have heard it and answered it had I not been in that attitude of heart so that he could consistently hear and answer. A beautiful little text in the Psalms strikes the whole matter: "If I regard iniquity in my heart, the Lord will not hear me." You know the promise is, "Whatsoever ye shall ask in my name it shall be given you." The thing asked for or prayed for must be in Christ's name; and he who expects answers to his prayers must in his daily life strive to follow Jesus Christ.

I now wish to give you a letter which came to me just a few days ago. Without the preface of a talk I have just given you, I should hardly dare put it in print. The good friend who penned it exaggerates in his kind comments on my poor self, or he does not know me very well. He has, perhaps, had only glimpses of that better spirit which occasionally shows itself through my actions. I only wish I deserved half of what he says. As he pictures forth in his letter what a good man and a follower of Jesus Christ *ought* to be, I have thought best to give it. When you read it, please do not think it belongs to me, but think of it as a beautiful sketch of what any Christian man or woman *may* be if really hungering and thirsting after righteousness.

Friend Root:—I wish to say that I have dealt with you during the past eight or ten years, and during all those years I have ever found you the same—obliging and accommodating, almost to a fault. If you made a mistake, you have always stood ready to correct it. If I made one, you kindly called my at-

tention to it. If goods were received damaged or short count, you always replaced them, even if to do so it cost you *double their value*. I do not wonder at your being overrun with orders, and that every other year or so you are obliged to enlarge your facilities to accommodate your increasing business. People will cheerfully send long distances, and pay heavy freight charges, when they know that by so doing every thing they receive will be just as it was represented to be. I have had considerable dealing with strangers, or people living at a distance, and I know a little of the self-denial it takes to meet complaints and bear losses for which one is in no way responsible. I have received much encouragement from your Home talks. It does me good to read of your trials and experiences, because they are so much like my own. May your life be spared unto us many years yet is my prayer. J. D. BRANDS.

Warrington, N. J., Sept. 30.

Perhaps it will be well to look into the circumstances that caused our friend to write such a letter as the above. He was one of the many whose goods were delayed last spring; and when the time came to make payment he was behind; therefore he wrote us as follows. You will observe that the date is earlier than in the letter given above.

Friend Root:—I believe that the time allowed me on your bill of June 19 will be up on Friday, the 19th inst. I fear that I shall not have the money by that date, but I think I may be able to pay you a part or the whole of it some time during the week following. The man whom I ordered the goods for refused to take them because of the lateness of the season when they reached me, so I am obliged to carry them over until another year. Will you please send me a postal, stating thereon the full amount, with interest, due you up to date? J. D. BRANDS.

Warrington, N. J., Sept. 15.

From the above you will see that our book-keepers had been asking him to pay interest. As soon as the transaction came to my eye I remonstrated against asking him for interest at all; but the book-keepers replied that this was according to the rule, and suggested that a different rule be made, where customers have been put out because of our delay in filling orders. Now, friends, please do not get the idea that I am the *only* one in our establishment who strives to love his neighbor as himself. The head book-keeper fell in with the suggestion with a hearty good will; and I find on the back of his letter she dictated about as follows:

"My good friend B., under the circumstances we shall make you no charge for interest, and you need not pay until another year unless it is convenient. If convenient to pay now, you may deduct interest on the whole amount of the value of the goods for one year."

Now, the above is only simple justice. Any supply-dealer who is so far behind in filling orders that the purchaser is obliged to keep the goods over until another season, should not ask pay for them until the customer is ready to order them for another season. If he has already paid for them, he ought to have a rebate equal to the value of the money, for the year he is out of the use of it. This is simply, in my opinion, doing as you would be done by; and even then it does not make up for the disappointment and perhaps heavy loss resulting from not having the goods when they were wanted. If we who are dealing in supplies will come up to this standard, perhaps it would help us to be a little more prompt in filling orders. It may be said, on our side of the question, that no one should wait for goods until he is ready to use them. This is true; but at the same time, every supply-dealer ought to be able to fill an order, say within 30 days after its receipt. If he can not he should pay damages to a reasonable extent. If the two parties can not agree as to just what the damages should be, I would resort to arbitration. Let me say, to the credit of our customers, that, although I have repeatedly asked

them to send in their bill for damages (where the fault was ours and not the railroad company's), as yet very few indeed have asked damages. Only one man has made a claim that we could not consistently pay. This man wanted \$25.00 damages where the goods he purchased really amounted to only about half that amount. We have only once been called upon to pay for the loss of a honey crop, and this was where the circumstances were very aggravating—see Homes for Aug. 1. This was where one of our clerks made Bracken County to read Breckenridge County; and as this blunder caused the friends to be looking for their goods day by day, and thereby lose the honey-crop, we decided to pay the full amount. The one who changed the name of the county paid \$8.00; the two women who passed that postal card by, paid each \$4.50 for their carelessness, and I paid \$18.00, making altogether \$35.00 for the loss of a honey crop.

Now, to those who say they can not stand such a way of doing business, I feel like repeating my favorite little text: "O ye of little faith! wherefore do ye doubt?" But, please remember that I do not advise that anybody should throw away his goods or money in a loose and slipshod sort of way. This would not be according to the Scriptures at all. In my talk about managing horses, in our previous issue, I told you the horse must be firmly disciplined, and that the rod should not be spared when *needed*. So it is in business. We are by no manner of means to let those who are evil-disposed run over us. To let people make their own terms in a lazy, shiftless sort of way, is entirely another thing. But when you have wronged a neighbor or customer by a delay or by a blunder, *make haste* to do as you would be done by; and as it is only human to be selfish, I would recommend that you go a little *beyond* the mark, to make sure of being just. Our text says, "Good measure;" and it also tells us that those who give good measure shall get good measure in return. Faith in God is a grand thing; and faith in a fellow-man is a grand thing also. When you give good fair measure and good quality, please have faith enough in your fellow-man to believe it will all come back again—yes, "shaken together and running over."

Now a few words more in regard to gaining the confidence, esteem, faith, and good will of this great outside world round about us. Who can tell what a reputation is worth? The Bible says, "A good name is rather to be chosen than great riches;" and, O my friends, I am sure—in fact, I become surer of it every day—that no one begins to know the half of the truth implied in this little text. The untutored savage—"savage" is not quite the word after all—the man or boy of the *world* who is profoundly ignorant of Bible precepts, and who knows nothing of the spirit of Christ Jesus, may be excusable for thinking that, if he saves a few cents each day by cheating and sharp practice, he will ultimately become rich. Ten cents a day would be \$30.00 a year, and in ten years this would be \$300.00. Why, he would not have enough to buy a farm, even if he cheated ten cents' worth every day for a *lifetime*. Yet a great many seem to think they can lay up property by *cheating*. Well, now, suppose, on the other hand, he *loses* 10 cents a day in the effort to be fair and honorable, and to give, in the language of the text, as he expects it to be given to him. He may be 10 cts. out of pocket for a few days, without getting anything back; but pretty soon somebody will feel grateful for these few cents given for *Christ's sake*, and he will remember it, and watch for an opportunity to pay it back. And, dear friends, it is only human nature for him to pay it back *twice over*, or more. It is also hu-

man nature for him to speak of it to his friends. "That man actually paid me 10 cents a bushel more for my wheat than he agreed to." You know I told you a short time ago of how Mr. F. Schumacher, of the Akron Mills, paid a man 10 cents a bushel more for his wheat than he agreed to pay. Such kind of work soon gets to be a big advertisement. It goes from mouth to mouth. People say, "That man is honest. You can depend upon it, he will do all he agrees to, and a little more, every time." Suppose a commission man who sells honey should commence by promising little, and in every transaction doing a little *more* than he promises. He would soon get the good will of the whole bee-keeping world. The reason is, that such things are so uncommon. Why, dear friends, there is a great unexplored region in this direction, in this matter of doing business according to the precepts of the Bible; and, oh what fun it is to just repeat one of these little Bible texts, when something comes up to make it fit just nicely!

Now, friends, I think you see the point of our little text; and you see how Christianity can be applied to business. "Fervent in spirit, serving the Lord." Do not, I beg of you, let A. I. Root monopolize this whole matter of building up a great business, with *Bible texts* for a foundation. Run opposition to him; beat him in his own line; *outdo* him in generous acts and love to your fellows. Don't you see how ridiculous it is? In Christianity there is *no* rivalry. There is not any select few in the prayer-meeting. If you have an enemy in the world, *there* is just where you want to see him, for he is just the man you long to do good to, above all other men. "Love ye your enemies, and *do good* to them that hate you." Do you fear there is no room in this world for us all, if we should *all* become Christians? "O ye of little faith!" The resources of a great Father above are beyond *all computation*. If this world in not large enough for the wonderful achievements that are about to be brought forth *in his name*, the whole planetary system is at his command. He *himself* has said (Malachi 3:10), "Prove me now herewith, saith the Lord of hosts, if I will not open the windows of heaven and pour you out a blessing that there shall not be room to receive it."

EDITORIAL.

He shall be like a tree planted by the rivers of water; and whatsoever he doeth shall prosper.—Ps. 1:3.

"GREAT INGENUITY."

On page 711 of our last issue (I won't lay it to the poor types this time) I notice I said, "It took very great ingenuity" to modify the Benton cage for introducing. I would say nothing about it, only it looks as though I were lauding myself pretty highly for making only a very slight improvement. What I meant to have said was, that "it took *no* very great ingenuity," etc. E. R.

NO REDUCED RAILROAD RATES FOR THE INTERNATIONAL.

In another column we give the programme of the I. A. B. A. It was not published as soon as was expected, because the secretary was waiting to hear what rates the Western Traffic Association would allow. After a long delay and much correspondence, we have been obliged to say we shall probably get no reduced rates. Remember the date and place of the next meeting,

Keokuk, Oct. 29, 30, 31, and come anyhow. Ernest and I expect to be present every day.

OUR DAILY BREAD.

WHEN I dine at the large hotels, or on the Pullman cars, I always pay particular attention to the *bread* and the way in which they serve hot cakes—the latter especially, if it is accompanied with nice honey. Well, during the last month or two we have been feasting on the nicest product in the bread line that it has ever been our fortune to hear of. And what do you think it is? Why, simply gems made of flour and water—not another thing, except a little baking-powder (we use Cleveland's), a teaspoonful to a pint of flour, to make them light. Mrs. Root found the recipe in a newspaper; and we prefer these gems so greatly to any thing else that all other kinds of hot cakes made of milk, eggs, etc., are abandoned. You will want a Hunter's sifter, then run your flour and baking-powder through it three times, to mix thoroughly, and to work in plenty of air. Now mix with cold water until right (say of the consistency of cake) to ladle with a spoon into the gem-irons. These should be heated on top of the stove until *quite hot*; then ladle in your dough, bake in a *very hot* oven, and pass them around. When I am in a hurry I just break one open, leaving it hinged at one side like a snuff-box (I do not like the illustration, but I can not think of any other). Open the lid wide enough to put in a generous slice of butter, spreading it along a little, then shut the lid down, and eat as many as you like. When you are pretty nearly satisfied, put in some alfalfa or mountain-sage honey, and you can then probably eat about as many more. You need a glass of milk to go along with them; and if you are doing severe outdoor work a small *pitcher* of milk right by the glass will come handy. If this sort of diet, "milk and honey," does not give you strength and vigor, there is something the matter. Huber says these gems just from the oven are as nice as hot popcorn balls; and, in fact, they *have* much the flavor of nice popcorn. While flour made of nice selected wheat is a little nicer for the purpose, you *can* make beautiful light cakes of the *cheapest* flour to be found in the market. In fact, the way we discovered it was by having a sack of flour that Mrs. Root said she could not possibly make into decent bread, and she had tried and *tried* until she was about as desperate as—your wife gets under similar circumstances. If your wife has some flour that will not make nice bread, then tell her to make it into gems as above. If you have not a gem-iron, use gem-tins or small shallow tin basins, or even pie-tins. They are nice, anyhow you can fix them; but, if you want the real *popcorn* flavor, you will need cast-iron gem-irons. They are just as good when cold, as any bread; and if we have any left over for supper, they always go off like "*hot* cakes."

THE HONEY MARKET.

The demand for honey still continues good, and we have already disposed of about one-third of each of the two car loads mentioned in last number; and those who received it are well pleased, as the following will testify:

OUR NEVADA COMB HONEY.

Honey arrived to-day in very fine condition. It is as fine as I ever saw. It fills your description exactly. Thanks for packing so carefully.

JAMES A. BOCK.

Farmington, W. Va., Oct. 8, 1890.

We can get more extracted honey of the same quality when this is gone; but comb honey seems to be pretty well taken up, and there is almost sure to be a scarcity this winter. Those in want of honey will find our prices in last number, 18 to 20c for comb, 9 to 11 for extracted, according to the quality you take.

THE DOVETAILED HIVE IMPROVED.

In another department of this number you will find a discussion of the merits and improvements on the Dovetailed hive as we are now making it for the season of 1890-91. We give here the revised table of prices, which you will find, by comparison with the old table, are a little higher in most cases. This slight advance is necessary because of the increased cost of the hive as improved. That you may understand the difference between the new hive and the old one, we repeat briefly the changes which we consider marked improvements. The hive and supers are $\frac{1}{2}$ in. wider: instead of being 11 $\frac{1}{2}$ inches wide inside, they are 12 $\frac{1}{2}$. This makes room for the addition of a dummy or division-board in the brood-chamber, which is to be first removed before handling the frames. This additional $\frac{1}{2}$ inch gives room in the supers for a follower and wedge, making it possible to have side pressure on the sections, which is so desirable. These division-boards, followers, and wedges are worth fully 15 cents per hive, and are added. Thick top frames with comb-guides or wire are used, and are worth a little more than the old style. Then there is the added width, a very small item. Out of the cost of these extras is to be taken the cost of slatted honey-board, which is left out entirely, unless ordered and paid for extra. We estimate the additional cost of these extras at 10 cents per hive; yet we have added nothing to the price of No. 1 complete, and only 5 cents to No. 2 complete, and 8 and 10 cents respectively to Nos. 1 and 2 empty.

We now make the bottom slats to the section-holders $\frac{1}{2}$ inch thick instead of $\frac{3}{8}$, as formerly, because a few have had trouble with the light bottoms sagging. Dealers who do not make their own hives, and those who supply their neighborhood, can find nothing more convenient to handle or that will give their customers better satisfaction. The hives are all packed complete in lots of 5, in the flat, as shown below.

5 DOVETAILED HIVES PACKED FOR SHIPMENT.

A box is made of the cover and bottom-boards, in which is packed the cleats and frames and inside fixtures, and the sides and ends of bodies and supers are cleated together as shown. You have to pay freight on nothing but the bare hives, and the cost of crating is reduced to almost nothing. Those wishing to handle them will do well to write for terms, stating about how many they can use.

DESCRIPTIVE LIST OF DOVETAILED HIVES.

None of these hives include tin on the covers or foundation for the brood-frames. Our experience is, that flat covers, well painted both sides, are better without tin; but we will add a sheet of tin, if so ordered, for 5c extra. If you get the tin, though, you will regret it. If you want to add the tin afterward, the cost of the tin alone is 10c.

No. 1 Dovetailed hive, 8 frame, complete, a $\frac{1}{2}$ story hive for comb honey, as shown in first cut on page 744, includes bottom-board; a body with eight thick top-frames and division-board; one super with a follower and wedge; 6 section-holders with tin separators, sections, and foundation starters, and flat cover.

No. 1E is the same hive leaving out the separators, sections, and starters; but every thing else mentioned is included.

No. 2 Dovetailed hive, 8 frame complete, includes just the same as No. 1, and another super with contents added, making a 2-story hive for comb honey.

No. 2E is the same as No. 2, leaving out separators, sections, and starters.

No. 3 and 3E are the same as No. 1 and 1E, except that they have T tins instead of section-holders in the supers.

No. 4 and 4E, same as No. 2 and 2E, with T tins instead of section-holders.

No. 5 Dovetailed hive, 8 frame, complete, is a 2-story hive for extractor, and includes bottom and flat cover, two bodies with 16 thick top-frames and two division-boards.

PRICE LIST OF DOVETAILED HIVES.

Order by number, and carry out the price.

NUMBER AND NAME.	Nail, part, each.	IN FLAT.		Weight of 10
		5	10	
No. 1 Dov. hive complete	1.50	1.20	5.50	10.00 390 lbs.
No. 1E, Dov. hive (empty)	1.00	4.50	3.00	280 lbs.
No. 2 Dov. hive complete	2.00	1.60	7.50	14.00 380 lbs.
No. 2E, Dov. hive (empty)	1.50	5.50	5.00	340 lbs.
No. 3 Dov. hive complete	1.50	1.20	5.50	10.00 300 lbs.
No. 3E, Dov. hive (empty)	1.00	4.50	3.00	280 lbs.
No. 4 Dov. hive complete	2.00	1.60	7.50	14.00 380 lbs.
No. 4E, Dov. hive (empty)	1.50	5.50	5.00	340 lbs.
No. 5 Dov. hive complete	1.60	1.20	5.50	10.00 340 lbs.
Hoffman frames instead of thick top frames 5c per hive extra.				
Closed end frames			5c	
Metal cornered			10c	
Van Deusen Reversible			10c	

In No. 5 the extra price for above frames is double above rate.

Honey-boards may be added at price in table of honey-boards.

Hives furnished with gable covers and super covers, instead of flat cover, 15c per hive extra.

Hives with tinned covers, 5c each extra.

The tin for covers ordered separately, 10c each.

We will make the Dovetailed hive 10-frame instead of 8-frame, in any of above numbers, as follows:

Nailed and painted, complete, 25 cts. each extra.

In flat, complete, 20 cts. each extra.

In flat, empty, 15 cts. each extra.

DISCOUNTS FOR QUANTITY.

For 20 hives, deduct 2 per cent. | For 50 hives, deduct 5 per ct.
For 30 hives, deduct 3 per cent. | For 60 hives, deduct 6 per ct.
For 40 hives, deduct 4 per cent. | For 80 hives, deduct 8 per ct.
For 100 hives or more, deduct 10 per cent.

NAILS SUITABLE FOR ABOVE HIVES.

	Price for 1	5	10
Nails for No. 1 Dovetailed hive.....	10	25	45
Nails for No. 2 Dovetailed hive.....	10	30	55

Nails for Nos. 3 and 4, same as for Nos. 1 and 2 respectively, and for 10-frame same as for 8-fr. hives.

PRICE LIST OF DOVETAILED-HIVE PARTS.

NAME OF PART.	N'd'd, each.	P'd'd, each.	IN FLAT.		Weight of 10
			each.	10

10 fr. Dov. super complete.....	.52	.55	.50	4.50	85 "

For the same quantity of parts the same discount will apply as on complete hives.

Vol. XVIII.

NOV. 1, 1890.

No. 21.

TERMS: \$1.00 PER ANNUM IN ADVANCE;
20 Copies for \$1.00; 5 for \$2.75; 5 for \$4.00;
10 or more, 75 cts. each. Single num-
ber, 5 cts. Additions to clubs may be
made at club rates. Above are all to
be sent to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY

A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS
than 30 cts. each. Sent postpaid, in the
U. S. and Canada. To all other coun-
tries of the Universal Postal Union, 18
cts. per year extra. To all countries
NOT of the U. P. U., 42 cts. per year extra.

HONEY STATISTICS.

OUR INDUSTRY GROSSLY MISREPRESENTED BY
MISLEADING AND INCORRECT REPORTS.

We take the following from the *American
Bee Journal* of Oct. 18, page 698:

The following is from the "Report of the Statisti-
cian," in the report of the Secretary of Agriculture
for 1889, page 251. I should like to call attention to
the last paragraph. Will not this be taken as con-
firmation of the Wiley lie, which is the basis of so
many newspaper reports derogatory to our pursuit?
Please ventilate the matter. H. G. BURNET.

Aliva, Fla.

Here is the Statistical Report which Mr. Bur-
net refers to:

BEE-KEEPING.

Among the minor branches of rural industry, bee-
keeping is one of the most important, though its im-
portance is not generally recognized, from the fact
that it is almost everywhere carried on as an incident
of general agriculture, and but rarely as a leading
rural occupation.

Every State and Territory reports bees and more
or less honey, usually a hive or a few colonies for
each farmer rather than extensive apiaries and large
production. In some localities, as in portions of
New York, Ohio, Tennessee, and California, where
existing conditions are particularly favorable, apicu-
lure is more prominent, dominating other indus-
tries in a neighborhood, though very rarely the lead-
ing branch of agriculture over any considerable
area.

The value of the annual product of honey and wax
is not generally realized. They are produced more
or less extensively in every section of the country,
and the aggregate value is large—much larger than
that of other crops of which more notice is usually
taken. It almost equals the total value of the rice or
the hop crop, falls but little short of the buckwheat
product, exceeds the value of our cane molasses, and
of both maple syrup and sugar. It largely exceeds
the aggregate value of our vegetable fibers excepting
cotton, and in 1879 was half as large as the wine pro-
duct of the year.

The latest official record of production by States
is the return of the national census for the year 1879.

It made the honey production 25,743,208 pounds, and
wax 1,105,689 pounds. After careful study of all
available data of local values and market prices, the
average farm value of the honey was estimated at 22
cents per pound, and the wax at 33 cents, making the
aggregate value of apianian products at the place of
production \$6,028,383. The product of the principal
States in that year was as follows:

STATES.	HONEY. lbs.	WAX. lbs.
Tennessee.....	2,130,689	86,421
New York.....	2,088,845	79,756
Ohio.....	1,626,847	56,333
North Carolina.....	1,591,590	126,286
Kentucky.....	1,500,565	46,912
Pennsylvania.....	1,415,093	46,610
Illinois.....	1,310,806	45,640
Iowa.....	1,310,138	39,565
Virginia.....	1,090,451	53,200
All other.....	11,678,184	524,984
Total.....	25,743,208	1,105,689

Under the head of "all other," in the above state-
ment, there is grouped the production of 36 States
and Territories, ranging from 1,056,034 pounds of
honey in Georgia to 50 pounds in Idaho.

The census of 1870 was defective in its returns of
product for many crops, and its record of honey and
wax in 1869 is undoubtedly much too low. It made
the honey product only 14,702,815 pounds, too low in
the aggregate, though the falling off in all States in-
dicates that it was a year of short production. Illi-
nois was the leading State, with a crop of 1,500,000
pounds, while North Carolina stood second.

The returns in 1860 were more satisfactory, and
they show that the product of 1859 was but slightly
exceeded by the crop of 1879, after 20 years of growth.
The production of wax was actually greater. Many
States show a product greater than that of 1879, and
the aggregates of 23,366,357 pounds of honey and
1,322,785 pounds of wax indicate that there has been
a comparative decline of the industry, the increase
of population being taken into consideration.

The nine States given in the preceding table as
those of principal production in 1879, produced 14,000,-
000 pounds. The same States 29 years earlier had a
record of 13,900,000 pounds. With our rapid annual
increase of population, to stand still in aggregate
production is to retrograde. A more striking way of
showing the decline in the industry is by a study of

the comparative supply of the product at widely separated periods.

Our foreign trade in honey has never been large, and the balance has fluctuated. During five years past our average annual exportation has been valued at only \$82,489, and importation at \$52,891, making the value of the net exportation only \$29,598. This little exportation goes principally to the United Kingdom, France, and Germany, while our foreign purchases come mainly from the West Indies and Mexico. The balance of trade is too small to affect the supply, and our domestic consumption is satisfied with our home production.

In 1859 our production was 23,366,357 pounds, and our net importation not far from 3,000,000 pounds, making the supply available for consumption that year approximate 26,000,000 pounds. On the basis of the population June 30, 1860, this was a *per capita* supply of eight-tenths of a pound.

Twenty years later, when tremendous advances had been made in almost every branch of industry, the production of honey amounted to only 25,743,208 pounds, and the official records actually show a net exportation of honey, or something shipped as honey, amounting to about 570,000 pounds, making the net supply available about 25,000,000 pounds, or a million pounds less than at the first period. The supply per head was less than five-tenths of a pound. During the same period the *per capita* consumption of sugar and other sweets increased. Wealth and the ability to gratify taste for luxuries are greater, and yet the data seem to show a reduced consumption of this luxurious sweet.

So anomalous does this appear that some explanation must be found. If the supply per individual unit had been the same in the last period as the first, it would have required a product of 40,000,000 pounds. What has taken the place of honey in domestic consumption? Does the enormous increase in the manufacture of glucose and other saccharine adulterants indicate that a fraudulent article makes up the remainder of the needed supply? Did our people in 1879 consume 15,000,000 pounds as substitutes, in the belief that they had the genuine product of the hive? Such would be a reasonable explanation of the comparative decline in bee-keeping.

We heartily indorse (as also will every intelligent reader) the vigorous reply made by the editor, Mr. Newman, to a report so manifestly incorrect and absurd. He says:

The statistical table referred to, from the Census Report of 1880, is manifestly incorrect. One simple item will show its error so palpably that no further words will be necessary. California's honey crop is the largest in any State, and yet in the Census Table it is credited with only about one-half as much as Arkansas, one of the States producing but a comparatively small amount of honey!

It also gives North Carolina credit for 50 per cent more than Michigan, and more than Illinois or Iowa! Such "statistics" are very misleading, to say the least.

Our estimate, based upon statistics gathered by us some years ago, is, that there are 300,000 bee-keepers in the United States and Canada, and the average annual product is 100,000,000 pounds of honey. Our tabulated statement by States may be found on page 320 of the *Bee Journal* for 1881.

It is a notorious fact that the statistics given in the census of 1880 are utterly unreliable. This was admitted by Col. C. D. Wright, Chief of the Bureau of Labor Statistics at Washington, who was one of the principal persons who directed the formulating of the census that year. In an address delivered before the Social Science Association at Saratoga, N. Y., in 1887, Col. Wright reviewed the whole census matter, and pointed out its shortcomings, and then said:

These two questions—capital invested and average wages—as answered by the census, illustrate the fallacy of attempting to solve a certain line of economic questions through the census as it has existed. In making this criticism, let it be understood that I arraign myself as severely as any one else; for within a few years I have followed, in all the census work in which I have been engaged, the old form. Nor did I fully comprehend the enormity of the error, and the infinite harm it has done, and is likely to do.

With this admission by Col. Wright, of the unreliability of the Census Report, we are surprised that the statistician, Mr. J. R. Dodge, should attempt

to make it prove that the industry of apiculture was declining.

Upon one erroneous conclusion he bases another argument; viz., that, because of the decreased honey production, the people have been annually "consuming fifteen millions of pounds of substitutes, in the belief that they had the genuine product of the hive."

By intimation, the statistician indorses the Wiley lie about manufactured comb honey, years after it has been exploded and acknowledged to be a falsehood, by its author!

No, sir; your conclusions are as erroneous as your premises. The production of honey, instead of being only twenty-five millions of pounds, is over one hundred millions—four times as much. Its increase has kept pace with other products; and it is the "pure product of the hive," too.

It is too bad that such incorrect and damaging statements and arguments should be published by those who ought to know better; and, going out under the indorsement of the government, they not only deceive those not posted, but also form the basis for other falsehoods.

The above illustrates vividly the result of setting somebody to collecting facts who is entirely unacquainted with the matter in question. It is the old story over, of going to Agassiz and Tyndall to know about the natural history of the honey-bee, when a bee-keeper in his teens could have told either of them what idiots they were making of themselves. This is strong language, I know; but I think it is time that something were done. We pay out our money to somebody supposed to handle the matter in question, and the above shows the result. Any bee-keeper in our land, at all conversant with our journals, could have told the statistician that California has of late years been furnishing more honey than half a dozen fair honey States, and that Arkansas is almost entirely unknown in the industry. It may be that Arkansas has undeveloped resources; but I do not remember that a large report has ever been made through our journals from that State, and yet there are dozens of States comprising bee-keepers who produce honey by the carload. The old adage, "Every man to his trade," is what is needed here. The statistician should be a bee-keeper himself, or else he should consult some intelligent, thoroughly posted bee-keeper. The editors of any of our journals could readily point out a competent man at any time; and so with statistics in our other industries.

SWARMING AND SECTION HONEY.

FRIEND DOOLITTLE SUGGESTS HOW TO RESTRAIN SWARMING AND ENCOURAGE HONEY-STORING.

My excuse for writing this article out of season (if any article on bees can be out of season) is from the fact that a party in Colorado is considerably agitated over the matter, and wishes me to write an article on the subject as soon as may be. The party says they have no trouble in following the ideas I have sometimes advanced in regard to spreading the brood, which our good friend Mrs. Harrison was sure might be misleading to some, for there was no trouble in getting the hive filled with brood and bees by the time the honey harvest from alfalfa arrived by using the plan; but the trouble was, that

when the hives were thus filled and the flow of honey occurred, excessive swarming was sure to result, which gave a loss in honey and often in queens, owing to the fact that the queens were not allowed to go with the swarms. Swarming, when working for section honey, can not very well be avoided, or at least I have not been successful in avoiding it without sacrificing a large amount of the honey crop. In fact I would as soon have *excessive* swarming as to try to hinder swarming altogether; for in this hindering process, by any of the plans with which I am acquainted, where the ordinary hive is used, the bees are so thrown out of their normal condition that they will not work to the best advantage. Again, I think that a mistaken idea prevails with some in thinking that the brood-chamber to the hives must be kept full of brood the whole season through. This is not the secret of a successful honey production, but it lies in having the brood-chamber filled with brood before it is filled with honey. Thus doing, we get the laborers for the first harvest, and, so far as my knowledge extends, when the brood-chamber is thus filled at the time the honey-flow commences, there will be bees enough reared for all practical purposes after this, even though the combs may be filled later on, two-thirds full of honey. There are two plans or ways of management which can be used successfully during the swarming season, in this locality; and if I lived in Colorado I would try them there, and then, if they did not work, I would study something else. Right here I wish to say that no one should follow any of our writers blindly, that is, without having some thoughts of their own, thoughts which will lead them out in all directions from the beaten path of a Langstroth, a Quinby, a Root, a Dadant, a Doolittle, or any other writer. Don't be a machine, but be the *master* of a machine, or of any thing else you may take hold of. So when you find yourself confronted with the swarming problem, or any other, master it, if it "takes all summer," and do it by *your own* planning, or the modifying of some plan that you have read or heard about. In this way you will grow; and by telling us how you did it, in some of the many journals of our day, you will help some one else to grow; and thus we shall be of mutual benefit one to the other, just as the all-wise Father designed we should be. "No man liveth to himself, and no man dieth to himself." But, to return: When a swarm issues, and while it is out in the air or clustered, go to the hive from which it came and take out all the frames of brood and put in their places frames of empty comb, frames filled with foundation, or frames having starters on them, as is best pleasing to you, returning the surplus arrangement on the hive as it was before; and if the swarm is a large one, it is well to give additional room by way of surplus sections. Now hive the swarm back in the same hive, or let it return if the queen has her wing clipped. Set the frames of brood with the adhering bees in a hive on a new stand, and in 24 hours give a mature queen-cell or a queen, according to what you can supply. This should satisfy any colony; but if the swarm on the old stand persisted in swarming out in a day or two, or in a "week's time," as the writer says they often do, then I would cage the queen for from a few days to two weeks, according to circumstances, after which I would release her. This is on the plan of doubling our colonies each year. If I wished no increase, then I would put on a queen-excluder after putting in the frames below, or after putting these frames in the brood-chamber where the frames of brood were taken from, and on top of this I would place the hive containing these frames of brood, while top of this last I would put

the surplus arrangement that was on the hive when the swarm issued. This should do away with all further swarming, but it results in filling these combs which now have the brood in them, with honey, which must be extracted, while it lessens our crop of section honey just that much. Now, if, instead of putting this hive of brood immediately on top of the queen-excluding-honey board, we place the sections there and then place the hive of brood on top of the sections, we shall get our honey mostly in sections, but we shall not be as sure of stopping all further swarming, for, as the bees hatch out from the brood above, they will crowd below, thus making the colony appear more populous than it did in the other case. If the sections were open-top sections, then it would not appear more crowded, for the bees would be equally distributed throughout the whole hive, but in this case we should have our section honey badly travel-stained, which is about the same as having it in the brood-combs, as we did where the sections were top. To obviate this I allow the bees a passageway only at the outside of each of the outside sections, which is done by a slot in the outside boards or sides of the case or section-holder. In this way the colony is kept together and good results secured, and should work in Colorado, it seems to me.

Borodino, N. Y.

G. M. DOOLITTLE.

UNCAPPING-BOX.

A MOST EXCELLENT DEVICE.

On page 30, Vol. 17,^[1] Mr. Root promised the readers of GLEANINGS a description of my uncapping-box; but as he has not fulfilled his promise yet, I will try to help him out. It was made by R. Wilkin about 12 years ago, and was so well planned that I should not care to have it changed in any way now. It is 2 feet wide, 2 deep, and 6 long outside, made of $\frac{3}{4}$ lumber dressed on both sides. The bottom is 2 inches lower in the middle than at the sides, and is lined with tin to keep it from leaking. Eleven pieces of wood, 1x1x22 inches, are laid across the bottom about 6 inches apart to support the screen which the cappings fall on. This leaves room below the screen for the honey to run to one end,

M'INTYRE'S UNCAPPING-BOX.

where it passes out through a tin pipe. Two pieces, $\frac{3}{4}$ x3x72 inches, are nailed on the top edge, one on each side, to contract the top of the box to the same width that a Langstroth hive is long inside. Two pieces, $\frac{3}{4}$ x $\frac{3}{4}$ x18 $\frac{3}{4}$, nailed one on each end between the two last mentioned, bring the ends up even with the sides. One piece, $\frac{3}{4}$ x3x18 $\frac{3}{4}$, is fixed across the top of the box about 14 inches from one end, with an iron pivot sticking up through it, 1 $\frac{1}{2}$ inches high to rest the combs on. When uncapping you set one end of the comb on this pivot, uncap one side, whirl it around, and uncap the other side, and set the comb in the end of the box, as in the diagram. When we have a surplus of combs we often hang them in the other end like B, in the diagram. C is cappings, and D the space for the honey to run out.

The bottom of the box is 7 inches from the floor, which leaves room for the honey to run into the strainer illustrated on page 248. This makes the top of the box about 32 inches from the floor, which is about the right height for me to uncup easily. A shorter person might make the box a little shallower, or lay a plank on the floor to give the right height, which is the way I do when my wife uncups. I know most people will think this box unnecessarily large. I will tell you why I think it is not. When uncapping over a round can like Dadant's, the cappings fall on top of those taken off earlier in the day; and when the can is half full the honey has to pass through such a pile of cappings that it takes a long time to all run out; and when you put the cappings in the sun extractor they are heavy with honey. With this box, when a pile of cappings accumulates under the knife we take a four-tined fork and pitch them over to the other end, where they may drain for four or five days. There is a small stream of honey running out of the box all the time, day and night, during the extracting time; and when the cappings go into the sun extractor they are almost dry. I think it pays well for the extra space in the box, because all the honey which goes into the sun extractor is spoiled for the market. J. F. McINTYRE.

Fillmore, Cal., July 27.

Friend M., I have had experience enough with uncapping to appreciate every point you make; and our good friend R. Wilkin ought to have a shaking for not giving this to the world long ago. I think I can say for the rest, that we bee-keepers tender you and Mr. Wilkin both a hearty vote of thanks.

HON. R. L. TAYLOR.

HIS HISTORY AS FARMER, BUSINESS MAN, LAWYER, BEE-KEEPER, AND SENATOR.

To my mind, the most alarming feature of the census just taken is the rapid increase of population in the cities and the corresponding decrease in the rural districts. Who has not noticed, during the past ten years, the constant influx of energy and strength from country to city? The men of push and ability who are leading our enterprises to-day, not only as business but as professional men, spent their boyhood on the farm. True, we have an Adams family, but we have hundreds of such men as Greeley, Webster, Lincoln, and Garfield, that went from country to city, and carried life, vigor, and energy with them. What will become of our cities if the country fails to pour in this new and vivifying power?

Our respected friend R. L. Taylor, Senator in Michigan, and President of the National Bee-Keepers' Association, had the advantage of country birth. He was born on a farm at Almont, Lapeer Co., Michigan, Nov. 3, 1839. This was not the only vantage ground of our young candidate for a place of influence in the world. He was the son of Scotch parents who were pioneers in that new heavily timbered part of Michigan. We need hardly say more to prove that our friend was early taught to be religious, truthful, honest, and industrious, for how loyal are almost all the Scotch to all these grand principles, which are the very basis of true manhood! When I add to all this the fact that the parents were sturdy and vigorous, able to carve out a home in the forest wilds, I have said enough to show that our friend was born to unusual fortune. The mother, though a pioneer farmer's wife, and mother to fourteen children,

still lives in good health, at the age of 79. Ten of the children still survive. President Taylor is the oldest of the six surviving sons. Like most farmer boys, young Taylor worked on the farm summers, and went to common district school in the winter. At the age of 19 he lost his father, who was carried off by an accident, when the severe and arduous duties of a large farm devolved on our friend. But he had learned to labor, and was equal to the emergency. But our friend aspired to a college education. He taught winters, and *prepared himself* for the Classical Department of the Michigan University, which he entered in 1862.

HON. R. L. TAYLOR.

In 1865, a thirst for business, which robs so many college students of their diplomas, took Mr. Taylor from the college. He entered mercantile life, which he followed at Almont very successfully for three years. But mere business was not wholly to Mr. Taylor's tastes, and so he spent his spare time—every determined man, however prompt in business, can find spare time—in the study of law. He was admitted to the bar in 1869. In 1872 he was elected Register of Deeds by the largest majority ever received by any county officer of his county. He then moved to Lapeer, where he has resided ever since. Two years later he was re-elected. In 1877 he resumed the practice of law, and was elected Prosecuting Attorney the following year.

At this time, fortunately for apiculture, two colonies of bees fell into Mr. Taylor's possession. His early life and habits had developed a taste for rural life and pursuits that had not left him with his youth. Country air and landscape still lured him toward the country, and led to the purchase of his present beautiful home in the suburbs of Lapeer. His bees increased rapidly, and his interest kept pace, owing, doubtless, to the success which marked his labors from the first. Thus he declined a re-nomination as Prosecuting Attorney, and very soon gave up the practice of law, that he might devote his entire time to his bees. Thus here as everywhere Mr. Taylor is consistent. He

preaches exclusive apiculture for the apiarist, and does what very few of his colleagues in this faith do—he practices what he preaches. He is, perhaps, the largest bee-keeper in our State.

As an apiarist he stands among the first. His cautious, scientific, thoroughly informed mind grapples even with foul brood, and the fell disease is worsted in the struggle. He told me once, as I visited his apiary, that he rather enjoyed the malady, as it was interesting to watch and study it. How few are cautious enough to hold this scourge at arm's length, even though it be right in the apiary!

Mr. Taylor is one of Michigan's best bee-keepers. The American Society is honored no less than Mr. Taylor in his presidency. He is so expert in bee-keeping that he can "feed back" at a profit, and can produce an immense crop of comb honey—his specialty—without any use of separators, and yet take the very cream of the market. Like nearly all successful bee-keepers he is very ingenious. Every thing about his apiary is neat, orderly, and convenient. His invention to fasten foundation in the sections is doubtless one of the very best in use. He uses the new Heddon hive, and would have no other. One has only to see him manipulate these hives and find the queens, to become convinced that, in his hands at least, they are a tremendous success.

Mr. Taylor's style as a speaker and writer is quiet, earnest, but very convincing. He is candid, very cautious, and rather conservative; so those who know him place great weight upon his opinion or judgment. Slow to draw conclusions, his conclusions rarely need reconsideration. In our literature, in our conventions, and, best of all, in his home city, he is a power. His presence is felt to be of signal advantage.

That Mr. Taylor's neighbors appreciate his worth is evinced in the fact that he was elected to our State Senate in 1888, where he was an able and influential member. He is renominated for the position, and, with almost no doubt, will be re-elected.

Mr. Taylor has been a member of the church for over thirty years. He is an elder in the Presbyterian church, and thus again honors and is loyal to his Scotch descent. But there is no need to publish the fact that Senator Taylor is a Christian. The fact shines out in all his life and acts. He is a true, clean, reverent man—one of the men that always make us feel better when we have associated with them.

Mr. Taylor has been married for nearly a quarter of a century. His wife is a fit companion for such a husband. Like her husband she takes great interest in religion, temperance, and all else that is good and helpful to others. Though they have none of those best adornments of the home—sweet, loving children, yet their home is one of those social centers that so richly bless every community where they are found.

Agricultural College, Mich. A. J. Cook.

Friend C., we all know you have a remarkable talent for studying bugs and insects; in fact, you often find out a thousand little things about them that perhaps the most of us would never notice at all. But I did not know before that you had such a rare faculty of taking in—or, perhaps I should say, *recognizing*—all these little individual traits that go to make up a man's character. My acquaintance with friend T. has been mostly at conventions; and as I read your description, point after point, it almost made me smile to see how carefully you have filled out the peculiarities and qualities. Why,

your pen-picture would almost enable one to know the man, even if the reader did not have the excellent portrait, furnished us by the half-tone process. We can all rejoice that friend T. has seen fit to take up bee culture—yes, even if he is a little severe sometimes on some of us whose loose ways of thinking and speaking contrast so strongly with his own cautious and careful ways.

THOSE CLOSED-END FRAMES.

ANOTHER ENTHUSIASTIC ADMIRER OF THEM.

During a few of the past rainy days I have been looking over Ernest's notes of travel, and I have laughed more than once while reading them since the Sept. 1st issue, and there are several others that have enjoyed it too. In 1886 there was a request in GLEANINGS for an expression concerning the reversing frame. I then expressed my opinion that they were good, but their full value would not be appreciated unless they were used with an end-bar $1\frac{1}{2}$ wide (the closed-end frame), and a division-board on each side, fastened in place by a wedge.

On page 641, Sept. 1, you make mention of the closed-end hanging frame used by Mr. Tunnicliff, in the hives of his 400 colonies. In a letter received from the Home of the Honey Bees in 1884, in answer to one I wrote concerning the wide end-bar, it is stated as dictated by A. I. R. that the wide end-bar was not practical, so far as rapid handling was concerned. Well, now, I should say that there is to be a change of opinion at the Home of the Honey Bees, or GLEANINGS is not an indication of the future. But let me give you a few points that may not have been noted by you, Ernest, on page 670, Sept. 1.

Several years ago I noticed that the wide-end-bar frame prevented that clogging of the ends of the narrow frames, and the hive with comb and honey; and the number of times that bee-keepers have said, "I wish the fools would put the honey where it belongs" is a strong argument for closed-end frames. Secondly, there is an air-chamber at the ends of the frames, preventing that needlike frost from extending between the combs in winter, which is another valuable feature. Thirdly, I place a strip of lath, 8 inches long, at each end of the hive, perpendicularly. Shove up one of the division-boards (I always use two), then your four or five frames, then your other division-board, and put your packing in good and tight, and your bees are just as well off as in a chaff hive, and in a single-walled hive at that.

I think I hear some of you say, "I guess not." Well, here is what I have tried and seen tried for several years. Make your hive $12\frac{1}{4}$ wide inside, bee-space at the bottom. The hive-body should be 9% deep, all around. To make the entrance, a strip of shingle one inch wide is pushed between the hive and bottom-board on each side of the hive (*a la* C. A. Stone, Southbury, Conn., 1878). The frames are then placed in as before described. Three strips of burlap, 20 inches wide by 24 long, are folded so they are 20x12; one of these is laid across the top of the frames, with the folded edge just reaching over the top of the opposite division-board. The other two are put in the same position for the other side, and the packing is put in. Now place on the top of the frames a half-length barrel-stave with a $\frac{1}{2}$ -inch-square stick tacked on the under side at each end. One of the burlap cloths from the side that the two are on is laid over the stave, then the one from the other side, and then the second of the two. Thus

we have six thicknesses of burlap on top, and a $\frac{3}{8}$ bee-space at each end, and nearly 2 inches of packing on each side. A folded newspaper is placed on the top of all, so it will just stick over all around and allow you to put on the cap. I have seen these hives stand in the most bleak and windy places in Connecticut, and there are a few of them that are bad enough. These hives have stood the test by the side of the chaff hive, and in every respect were preferred.

Right here I wish to say, that, with the wide-end-bar hanging frame, I, with quite a number of others, want two division-boards, one on each side. That is so that the hive can be opened from either side; and I like a long strip of wood 12 inches long as a key for each side, in preference to a thumb-screw, having used both because I can handle the wedge faster and easier. I prefer the lag strips on both sides of the division-boards at the ends $\frac{1}{2}$ inch thick, 1 inch wide, so that the division-boards, when they become sprung, can be turned around so as to spring them back by using the wedges.

With all this rigging and complication, I can handle fully twice the number of hives that I can with the common hanging frames, taking the season all through. But if you undertake to handle every comb separately, and have a very strong colony, it is a little slower; but in such cases I shake the bees from the comb in front of the hive, and keep right along. I have not been troubled with combs being so bulged that they would rub with the $1\frac{1}{2}$ -spaced combs, because I generally use full sheets of foundation; and whenever I have used only foundation starters I use them between full combs.

I tried the single reversing comb and the whole hive reversible for some time, with both wide and narrow end-bar frames, and I have been forced to accept the wide-end-bar hanging frame. It came slowly, and has been a bitter dose; but it is here; and for the L. size frame it has no equal. With me and some others it stands wide-end bars and reversing wires.

Try a few hives with frames $4\frac{1}{4} \times 17$ inches, inside measure, and try a cap with sides 13 inches deep, front, and $11\frac{1}{2}$ back, allowing the sides to project $1\frac{1}{2}$ inches below the front board of the cap. These deep caps have proved a very beneficial thing in three points. First, they make first-class protection in winter, late fall, and early spring. Second, bees will go into the sections quicker and earlier in the season, which is quite an item. Third, the bees do not desert the sections late in the summer.

Bees do not cluster quite so early in the fall, which here in Connecticut is quite an item; and this deep cap, wide-end bar, reversible frame, with the two division-boards and chaff-packed-bottom hive, will be the hive for that fourth class of bee-keepers mentioned on page 697. It has stood the test for years past in cold and windy locations, and in warm and sheltered places, with good results. H. L. JEFFREY.

New Milford, Conn., Oct. 15.

There is no doubt that the closed-end frames are a great deal warmer for winter. Both Elwood and Capt. Hetherington have urged that, and their statements are not to be lightly esteemed. With a division-board on each side, and closed-end frames, we shall virtually have a double-walled hive out of one made of $\frac{3}{8}$ lumber. While the idea is by no means new, I am glad you suggested it, for it is an opportune time for giving the plan a trial. For practical working, I do not believe that the majority of bee-keepers would like two division-boards. The bee-keepers I visited, using fixed distances,

used only one. It is true, the extra division-board gives added protection; but can not the exposed side—the side without the division-board—be pointed toward the south, or that direction from which comes the least cold wind?

MANUM'S MEDINA VISITOR.

MR. MANUM'S RECOLLECTIONS OF THE THINGS SAID AND DONE.

"Jennie, I wish you would step into the shop a moment" (the shop being adjacent to the house).

"Yes, sir; what is it?"

"There; do you think this box will hold all the lunch you have prepared for me to take to camp-meeting?"

"Yes, I think so; but how will you prevent the pies and cake from getting jammed if all are put in together?"

"Well, I am going to nail cleats on the inside, three inches from the bottom, and after the pies, etc., are put in I can fit another bottom over them and then put in more stuff, and then another bottom, and so on until the box is full."

"Oh, yes! I see; that will be nice."

"There, Mr. Manum; some one has just driven into the yard—two gentlemen and a little girl, in a carriage. I must scud back into the house, for they will probably be in here in a moment."

"I will step out and see who they are. Why! how do you do, Mr. Crane?"

"Quite well, thank you. I suppose you know who this gentleman is I have with me?"

"Well, I imagine it is Mr. Ernest, the lost child—or, rather, the one whose whereabouts for the past few days has been a mystery to me. Yes, I can see the 'Root' sticking out of his eyes, even though they are covered with glasses. How do you do, Mr. Root? I am glad you have got here at last," giving the "Root" a hearty hand-shake as he remarked,

"Yes, Mr. Manum, I am Ernest, and I feel that I owe you an apology for my conduct in not keeping you posted as to my whereabouts the past few days, as no doubt you would have been in camp with us on Lake George had you known I was there."

"Yes, Mr. Root, I had intended to join the party on Lake George, in company with you, as I had inferred, from what you and Mr. Larrabee had written me, you were to visit me sooner, and that I should have the pleasure of your company on the way to the camp. But instead, you went directly to the camp; and, as friend Larrabee expressed it in a recent letter, I was 'left in the soup.' But, as he reports a very enjoyable time, I will overlook it, and grant the pardon you ask. Now, Mr. Crane, let me put your horse in the barn, and we will have a visit all together. Let us go into the shop, as I suppose you will both prefer that to the house at present. Jennie will soon have tea ready, and then we will go in." So, into the shop we go, where we have a regular bee-convention.

"Now, Mr. Root, if you will tell me how many days you can stop with me I will plan a little in order to have you see as many of our Vermont bee-keepers and their apiaries as possible, for all are on tiptoe, and ready to spring at a moment's warning to give you a welcome."

"Thank you; you are very kind; but I must go to-morrow."

"What! go to-morrow?"

"Yes. I must be in Troy, N. Y., to-morrow night."

"Well, then, why under the sun didn't you stay at home? for surely this hurried flight through the State is far from satisfactory. How much more will you know about Vermont and her bee-keepers than you did before you came? Why, you must stay a week, *sure*; nothing short will be satisfactory to us; what say you, Mr. Crane?"

"Well, I am of your opinion, Mr. M.; but, just think; he stopped with me only a few hours; and if he stays with you until to-morrow afternoon you have no cause for complaint, as he assures me he *must* go."

"Very well, then, Mr. Crane; suppose you stay here all night, and we will make it 'warm' for the young Root before morning, as we will keep him up all night so as to make all we can of him while he stays."

"Really, it would be impossible for me to stay with this little girl," said Mr. Crane. "But I should like to, for I think the young man should be punished for not making us a longer visit. But my experience teaches me that *you* are pretty good at keeping your visitors up to a late hour, so I will risk you with him."

"Surely, gentlemen," said Ernest, "you are very considerate. I only wish I could remain a few days longer, but it is impossible."

"What is this you have here, Manum? This is something new, isn't it? I never saw any thing like it before. What do you use it for?" asked Mr. Crane.

"Why, Mr. Crane, is it possible that you do not take the papers? Why! this was illustrated, and its use explained, a year ago in GLEANINGS. It is my queen-nursery, and a useful thing it is too. There, you see one of these half-depth frames holds 16 of these little boxes; and by hanging a queen-cell in each and hanging the frame (nursery) in a colony, whether they have a laying queen or not, the cells will be kept warm, and the young queens will hatch as well as though they had not been removed from the combs. In this way I always have a quantity of virgin queens on hand; and since I have learned how to do it, I prefer to introduce virgins rather than laying queens. In fact, I have better success with them. I have introduced over 500 virgin queens this year, and I don't think I have lost over a dozen."

"Well, well!" exclaimed Mr. Crane; "why haven't I known of this before, Manum? Why haven't you told me about this thing before? I like it; it is the best thing of the kind I ever saw."

"Well, Mr. Crane, my answer is, Why don't you read GLEANINGS? and, furthermore, why don't you write for it? Again, why don't you come up and see me occasionally, as you used to years ago? I am the same Manum that I always was, only that I know less about bees than I used to in my own estimation."

"I see you have some of our excluding zinc here; how does it work?" said Ernest.

"Yes, I have enough for 65 hives; but it does not exclude the queens from the upper story, as I find that very many of my queens got up into the upper story this summer, so that really it is not safe to use it for the purpose of excluding queens."

"What is this used for?" asks Ernest.

"That is my section-gluer for putting four-piece sections together. A good smart hand will put together 1500 to 2000 per day with it."

"And what is this for?"

"That is a block with which I make my bee-escapes. This block has been in use over 15 years. You see it is simply an inch hole bored in this block of hard wood, and this is the 'punch,' made cone-shaped so it will fit the hole loosely. I now cut common window wire screen into three-inch-square pieces, lay a piece

over the hole, and with the wood punch I press the screen into the hole which forms the escape, making it cone-shaped, and then with the point of my knife I cut two of the wires at the tip of the cone crosswise—thus, $\times$ —and with an ordinary lead-pencil passed through the $\times$, the opening is made just the right size to allow one bee to pass through. Then I tack the escape over an inch hole at the gable ends of my hive-caps; and by placing my sections of honey under the caps, the bees will very soon pass out through the escapes and can not return."

"And here you have used these escapes over fifteen years, as well as many other (to me) new things which you have here, and have never told us of them. Now, Mr. M., why don't you mention these things and their use through GLEANINGS? It is these little useful things that we want; so hereafter, when you get up something new, please tell us all about it in your articles. They will interest some if not all who read GLEANINGS; and whenever you can, send us a photograph of them."

"Well, gentlemen, Jennie says, 'Tea is ready,' so let us go in and sample her cooking."

After tea Mr. Crane departs for home, and Ernest and Manum settle down for a good talk, and lay plans to make the most of the next day. I noticed all the evening that my friend Root was full to overflowing with thick top-bars and closed-end frames. Really, he did not seem to be interested in talking about any thing else; and I thought to myself, "This young Root has thick top-bars and closed-end frames well rooted within him; but to-morrow I will make an effort to root them out of him." So, having laid our plans for the morrow, we retired at a late hour.

"Good-morning, Mr. Root. The weather is rather unfavorable this morning for carrying out my plans, as you see it rains very hard. My intention was, since you must go to-day, to take you to Burlington, 25 miles from here, where you could take the 9 P. M. train for Troy; and on the way to Burlington I could show you four of my apiaries; then we would call on Mr. Eugene Cox, who has some 75 colonies; then next we would call on Mr. Fred Dean, who has 50 or more colonies; and then Mr. H. Stilson, with 140; and then Mr. W. H. Dodge, with his 200 or more colonies; hence you see I had planned to give you a lively time if it had been pleasant. But as it is we will just settle down and have a visit all by ourselves. I wish it would stop raining long enough so I could make a picture of you standing by my new hive hot-house; but as that is impossible, I will show you one I made a few days ago which I will give you to show to the readers of GLEAN-

MANUM'S HIVE HOT-HOUSE.

INGS if you care to reproduce it for that purpose. You will notice that it is simply one of my Bristol hives with a glass roof. I make a

shallow box just the size of my brood-chamber, and put in about four inches of earth, sow my seeds, and place the box over a strong colony early in the spring, and then place this glass-roof cap over all; and the warmth from the bees at bottom, and the heat from the sun at the top, will cause the seeds to germinate very soon; and the warmth from the bees will prevent the plants from suffering on cold nights. In this way I can have as many hotbeds as I wish; and, furthermore, these hives may be used for solar wax-extractors. And now, Mr. Root, the hour has arrived for you to take your departure. The stage is coming for you. I am very sorry you can not make a longer stay; and here let me say, that, whenever any of the members of the Home of the Honey-bees wish to visit Vermont bee-keepers, you send an *older* person—one that can not *fly* so swiftly as you can—the veteran *A. I.*, for instance—that we may have a little more time to visit. Notwithstanding that, I have enjoyed *your* visit very much indeed; but when I am favored with agreeable company I like to keep it as long as I can."

A. E. MANUM.

Bristol, Vt.

Most of the bee-keepers whom I visited felt that I was paying them a rather short visit; but I had planned, by getting copy ahead, etc., to be away for only one month. As I had to travel something over a thousand miles in all, and visit bee-keepers and friends all along the route, you can readily see that my time had to be put on rather short rations for each; and those bee-keepers who were situated on the latter end of the journey, I am sorry to say, got shorter visits than those I called on first.

I make this explanation, that the kind friends whom I visited, and others whom I may visit in the future, may know why I was in such a hurry. My trip in Vermont paid me well, and one day with you was a good deal better than nothing. I saw many things at your place that interested me. But I found along the route, that, when I visited a representative bee-keeper of the locality, I saw pretty much the same sort of bee-keeping within a radius of a hundred miles. You and Mr. Crane were representatives of your locality, and in a sense I saw a good deal of Vermont bee-keeping.

Now, really, about that queen-excluding zinc failing to accomplish its object. I am somewhat troubled about it. We had had reports that in exceptional cases the queen got through it; and you remember that Mr. McIntyre, of California, used these same boards with a good deal of satisfaction, while he admitted that occasionally a queen would get through. These reports, together with your own statement, influenced us to get a new set of dies; and now I am happy to state that they are made, and the perforations of the zinc are exactly $\frac{1}{100}$ of an inch—the size adopted by Dr. Tinker, and recommended by McIntyre. The old zinc we had (and which was sent you) measures about $\frac{1}{18}$ —at least some of the perforations. As it was too large it is no more than fair that we offer to make the matter right in some way.

MEDICAL FACTS,

FROM A DOCTOR WHO DOCTORS WITHOUT VERY MUCH MEDICINE.

We, and I think a great many thousands of the readers of GLEANINGS, are thankful that it has such extra good "Roots" that branch out in so many interesting and important subjects for the good of the people, when the bees fail to store surplus honey for us. It used to be said, that the *love* of money is the root of all evil. That was when preachers drank whisky, and used tobacco, without thinking of roots, good, bad, or medicinal. I used to think, and am now of the same opinion, that the science of medicine, as taught and practiced sixty years ago, was the root of more evil, suffering, and death, than all other evils combined. The science of medicine was called "scientific ignorance;" and the practice, "murderous quackery."

A great many quit the practice of medicine after finding out that they were doing more harm than good. An old doctor of the "regular faculty" in Ohio told me that he did not know that he ever cured a patient, and said that he knew he had killed some, but not intentionally.

For many years I have admired the candor and honest acknowledgments of Dr. O. W. Holmes. When he said, "It were better for the people were all the medicine of the world cast into the sea," he meant medicine used by the regular faculty, such as he had been taught to use. I don't think he meant water, honey, and other domestic remedies.

An experienced regular doctor in Louisville, Ky., told me that the people would be better off without than with such medicines as he used; but he said he had to visit patients, and they would not be satisfied without medicine. No wonder that homeopathic patients get along so much better when the doctor gives little sugar pellets without any medicine.

A reverend doctor of divinity told me that he quit the regular practice of medicine because the medicine did more hurt than good, and he had to lie to his patients. He also said he thought it necessary to lie to patients, or it was *better* in many cases than medicine. Many years ago one of my comrades was sick with fever, and the regular doctor said he would die, as most of his fever patients did; but in the night, when the watcher was asleep in his chair, the patient, "burning up with fever," tongue and lips cracked open, "dying with thirst," reached the pail or pitcher of water and drank all he could. When the doctor came the next morning he was surprised to find his patient better—saved by nature's remedy, contrary to the doctor's science and murderous treatment. Thank the Lord, the doctors are progressing, using more common sense, and do not ruin as many constitutions as formerly. One of the professors in the Ohio Medical College, in Cincinnati, said to us (the students of four medical colleges) in one of his clinical lectures in the hospital, that an old woman's remedy had done more good than all the remedies in the *materia medica*. He also advised the use of warm water and vapor baths.

In North Carolina, at one time in 1865, I sent a requisition to Wilmington for medicine, and failed to get any. Surgeon Thomas, ex-professor in Keokuk, Iowa, Medical College, said he would go himself after medicine. When he came back he said there was none to be had. I told him that I was a radical botanic and hydropathist, and could prescribe better medicines that were right handy by than were furnished by the government.

It is recorded in history, that Surgeon Daniel Tyrrell was frequently called to visit other

surgeons' patients after it was known that such cases as were dying, day and night, under "old school" treatment, were getting well under his botanic (physio-medical) treatment. In Rome, Ga., in 1864, one doctor who belonged to the regular faculty lost seven patients in one night, and said to me that he thought four or five more of his patients would die before the next morning. He had only three wards and but few patients, while I had six large wards well filled with sick and wounded, and more being brought in from the field and field hospitals every few days, and I lost only one patient in over a month. The said regular had proclaimed with an oath that there ought to be a law to prevent all doctors practicing medicine who did not belong to the "regular faculty."

One fact more: I think I have saved many lives by giving enemas of lobelia in plenty of warm water, and frequent drinks of pleasant herb tea. If the regulars knew how to use lobelia for inflammation of the bowels, they might save such cases instead of letting them die with opium or morphine. The whole system can be relaxed, and inflammation in any part subdued with small but frequent doses of lobelia to stomach or bowels. The addition of lobelia is better for dysentery than clear hot water, which is good, "you know." D. TYRRELL, M. D.

Toulon, Ill., Oct. 8.

SAWYER'S BEE-ESCAPE.

A DIFFERENT PRINCIPLE.

I mail you to-day a model of my bee-escape. I have been using it the last two weeks, taking off comb honey from 76 stands of bees, with perfect satisfaction, not leaving more than three to ten bees in the supers, even when I raise two supers at a time.

To make the escape, cut a slot in the honey-board, 12 in. long and $\frac{3}{4}$ wide, and bevel out one side. The wire cloth is to be cut 14 in. long and $2\frac{1}{2}$ wide. One side and both ends are to be fringed $\frac{3}{4}$ inch, the fringe coming over the beveled side of the slot. I use a honey-board $\frac{1}{4}$ in. thick, with a bee-space top and bottom. By having a thicker board, the escape could be made within it so as not to interfere with the bee-space, by cutting some of the wood away in the board. The slot in the board must be made in a line with the opening in the sections. I use the same honey-board for covering the brood-chamber and sections by closing the slot when not in use.

I am an A B C scholar, and have been reading GLEANINGS since 1885. I have been much interested in it, especially in Reese's and Dibern's bee-escapes, as I have been anxious to get something that would work satisfactorily.

I should like to have you try it before the season is over; and if you think it is the best out, I should like you to supply brother bee-

keepers with models at 30 cents for one and 50 for both, if you can at that price, and pay me what you think right. JAMES SAWYER.

Du Quoin, Ill., Sept. 17, 1890.

Friend S., something quite similar to the above has been in use for years, but it was not applied to a honey-board. I will explain to our readers, that the engraving does not show the edges of the wire cloth raveled out sufficiently. The bevel in the slot should reach to the edge of the fringe on the wire cloth; and the wire of which this wire cloth is made should be so light that the bee raises the end as it crawls out under it. I discarded a similar arrangement years ago, because the wires were so easily doubled up if any thing touched them. Now, it occurs to me, however, that a thin piece of wood or tin could be so placed as to protect these fringed ends from injury. Arrangements of this kind work positive; that is, a bee can, under no circumstances, get back after he is once pushed out under the points of the wires.

ERNEST'S NOTES OF TRAVEL AMONG THE BEE-KEEPERS OF YORK STATE.

ON THE CATSKILL MOUNTAINS.

After romping around Shady Glen (and it seemed to me that the parts of York State I visited were full of them) we rambled back to the hotel—brother Charles and I. Glancing back I noticed the whole front range of the Catskills—a most beautiful sight to me, as it was my first initiation to mountain scenery. There were several gentlemen at the hotel, who, I had been told, were discussing my bicycle trip of the day, and with doubtful heads agreed that it was impossible. To settle the matter, one of them was introduced to me. "Why," said he, "I have been driving all day with a good horse, and have gone only 30 miles; and here you say you went 45 miles in about five hours and a half."

"That is easy to explain," said I. "When you are going down hill you are obliged to walk the horse; and likewise in coming up the hills."

He assented.

"Now, then," continued I, "when I go down hill I coast"—that is, I let the bicycle out to almost its full speed if the road is not too rough; and I travel, I suppose, on an average, when going down hill, at the rate of about a mile in five minutes, and sometimes much faster. If there is another hill just ahead of me, with very little effort I can keep up the velocity acquired down; and the result is, I can ascend the next hill with very little effort. If it were not for friction, by the well-known law of mechanics I could ascend the next hill without trying at all. Now, then, I do not lose time in going up and down hill, as you do with a horse."

"Oh!" said my friend. "I see. It is all plain now."

By this time the supper-bell rang, and I think I managed to do ample justice, after the exhilarating ride. Not long after, Mrs. Root came back. She had received a letter from O. R. Coe, of Windham, N. Y., inviting us to visit him. It will be remembered that he has written occasionally for the journal. He owns between 200 and 300 colonies, and is also proprietor of one of the best hotels in the Catskills.

I was to wire Mr. Coe when we were ready to leave for Windham. Accordingly, after dinner the next day, I took the wheel for the village, three miles away. It looked somewhat like rain, but I thought I could get back before it actually began to storm; but, unfortunately, it poured and poured, when I had got just about half way. Hurrying as fast as I could, I forgot to observe the direction I was going, and I got on the wrong road, a couple of miles out of my way. Back I came through the mud and rain, dripping wet. In some places the hills were so steep that I had to dismount and plod along by the side of the wheel, with great clods of mud hanging to my low cloth bicycle shoes. I finally reached the village, sent the telegram, and started back. The roads began to dry off from the effects of a downpouring sun; and before long I was back at the hotel, pretty nearly as dry as when I started out, but somewhat muddy.

We were about to go in to supper when a mountain wagon drove up, bearing the name "Windham Hotel." A middle-aged man stepped out, whom I took to be Mr. Coe. Advancing toward me he said, "This is Ernest, I suppose?" I then introduced him to Mrs. Root and to my relatives, Mr. and Mrs. Bedell. As it was a little late, we took a lunch, fastened the bicycle on the wagon, and started on the road to climb an elevation of about 1200 feet for Windham, eight miles distant—a point in the heart of the Catskills. It was growing dark fast, and we did not see very much scenery that evening. In the meantime, Mr. Coe and myself talked bees as only two bee-men can. He has kept them for a good many years; but on account of difficulties in wintering he had lost about as much as he had put in. He could bring them through the winter well enough; but along in the spring he would invariably lose heavily from spring dwindling. He had tried all the best methods for wintering, both indoors and out, but he invariably encountered that dread malady along in April and May. The curious thing was, that, with all his modern improvements, box-hive men would carry through successfully their black bees. The result was, that, in order to carry on bee-keeping, he was obliged to buy from them, transfer, and start anew. I suggested that it might be that the black bees would winter better than his Italians. No, that could not be it, because he had tried in vain to winter black bees. "Why," said I, "why don't you leave them in your single-walled hives outdoors, as your box-hive friends do?"

"I did try that, and still they would die."

The facts were, he was about 1500 feet above the general level of the surrounding country. The winters are very cold and severe; the springs backward, and generally unfavorable to the bees. There is no doubt that Mr. Coe has conditions to combat against that many of us generally do not have. But there were those old box-hive bee-keepers—how is it that their bees, apparently neglected, came out all right in the spring? That was a conundrum that I, a supply-dealer, editor, and an advocate of modern improvements, could hardly answer, and I should be glad if any of our readers would solve it. Mr. Coe had as good a wintering repository as I have ever seen. He has practiced all the best methods, tried all the different ways of ventilation—done every thing, in fact, and yet the general result seemed to be the same in the spring.

On this ride Mr. Coe also explained his project of moving his bees to the alfalfa regions of the West. He would either move them this fall, or very early next spring, before spring dwindling had a chance to commence. He desired to know what I thought of it. I told him

I thought it risky business. The alfalfa fields seem to be boundless in their resources for nectar, and he might make a big failure of it, or a big success. At best, moving bees so far is hazardous. To this he explained that he would lose them all anyhow, if he attempted to winter them at home, and he rather decided to accept the other horn of the dilemma—sending them to the alfalfa regions. He had some 500 hives filled with nice perfect combs on which the bees had died, the same carefully stowed away in his bee-house. This was capital lying idle, and he would never be able to use it or sell it *unless* he could move the same to a locality where he could both winter the bees and get paying crops of honey.

This was about the strain of our bee-talk on that pleasant evening ride; and ere long we ran up to a large four-story hotel, with accommodations, if I remember correctly, for about 60 guests. It was so dark that I did not recognize the place from the pictures I had seen of it; but that you may get a view of it, I will ask Mr. Coe to send an electrotype, that you may all see the place.

After being introduced to Mrs. Coe and to his son and daughter, we were conducted to our room; and the next morning, from the window there was revealed a beautiful view of the mountains in the rear of the hotel. What a lovely place, we thought! It would be delightful to stay here during the summer months—cool and bracing, even during the hottest weather; never any malaria, and always good sight-seeing!

OFF TOURING AMONG THE MOUNTAINS.

The evening before, Mr. Coe had told me that he was going to make up a party of two loads to drive among the mountains, the objective point being the Mountain House, and the now almost world-renowned Kaaterskill. The latter, I suppose, is one of the most magnificent and expensive structures for the accommodation of guests that was ever built. It was erected under circumstances which I will presently explain.

After an early breakfast, Mrs. Root and I, together with a party of several others, took seats in one of the mountain wagons. These wagons look very much like ordinary stages. They have three seats, each holding three persons, or nine in all. As I have before remarked, these mountain horses seemed capable of performing marvels in drawing these heavy loads. They have learned to economize their strength, and I suppose they will last about as long as the average horse on roads more level.

As we climbed into the wagon, Mr. Coe handed me an aneroid barometer, which he had purchased of A. I. Root, saying, "Here, you may carry that."

"What is it for?" said I.

"Why, it is to record elevation. You can tell at any point in your journey just how many feet you are above the surrounding level."

It then flashed through my mind that barometers are used for that very purpose.

"Now," said he, "notice where the pointer stands on the dial, for we are going to climb the mountains to-day."

Up, up, and up we went; and as we ascended, the little pointer on the dial recorded the number of feet we ascended in a perpendicular, until we were 1000 feet higher. What astonished me was, that several times when we appeared to be going down hill that dial showed that we were actually *ascending*; and sometimes it would behave the other way. It seemed to me that it did not know what it was about; but it was evidently correct.

At one point I remember Mr. Coe called out,

"Now, ladies and gentlemen, perhaps you would like to get out and walk a little, and get rested." After riding a good many miles we were glad to avail ourselves of this suggestion. On arriving at the top we were also glad to get in and ride down hill. Again the little aneroid barometer was consulted. Yes, down the hill the pointer indicated—300, and finally 500 feet lower. I noticed that, even for a few feet of the descent, it recorded it quite accurately.

I was curious to observe that some peaks appeared to be very much higher than others. Mr. Coe informed me that such a peak, pointing to one that seemed very much lower, was in reality 1000 feet *higher*. As we rode along, every once in a while a panorama of scenery would open up as a clear space between the trees gave us a view. The Catskills, unlike the Rockies (the latter are the result of upheavals), were made by glaciers; and by intently looking at the rocks, and the peculiar formation of the valleys, as well as the shape of certain peaks, this explanation seemed to be very reasonable. It seemed funny to think that this rugged and mountainous country might at one time, before the advent of the glaciers, have been level, like our own State of Ohio. Just how long ago that was, etc., I will leave to the geologist.

AT THE MOUNTAIN HOUSE.

We went through two or three little villages that seemed to be sustained largely by pleasure-seekers during the summer; and finally we were told that we were in the vicinity of the Mountain House and the Kaaterskill Hotel, and presently we were in the rear of the former. After stepping out of the wagons, our party passed through the long hallway, then out into the front, on to a large table rock. Here we were, something over 2000 feet above the valley of the Hudson River, overlooking an immense cliff—a veritable balloon view it was indeed. Two thousand feet down—what a sight! map-like, here a village and there a village, and the roadways winding hither and yon. The country beneath seemed to be perfectly flat; but I was told that it was quite hilly. Twelve miles distant (it did not seem half that far) was the Hudson River. Mr. Coe handed us a field-glass. Off in the distance the day boat from Albany was seen going down the river to New York city. Further on were some of the mountains in Vermont. In all my boyhood days I have always desired the privilege of a balloon view, that I might look down upon the country, and view its maplike appearance; and here I was with this aspiration fully realized, but without the attendant dangers of aerial navigation.

Our next point was the celebrated Kaaterskill. Just as we were about to leave I noticed a young lady and her beau. Like many another gallant suitor, he essayed to climb down a ledge of the cliff a little way to pluck a little mountain rose that the girl admired and expressed a wish for. As he clung nervously to a little niche of the rock I fairly held my breath for fear he would lose his scanty hold and be precipitated a thousand feet below. If he had performed this feat to rescue a little child, I would have taken off my hat in admiration. As it was, I thought, "What a poor silly fool he was, just to gratify a mere whim and fancy of a girl, who could not have loved him much!"

Through a winding and narrow path we clambered from one ledge of rock to another, till that magnificent hotel, the Kaaterskill, came into sight—a structure that had cost over a million of dollars, and its origin was—what do you think?—a chicken. "Oh, yes!" said I; "we want to hear

THAT CHICKEN STORY."

To this Mr. Coe readily responded. A certain rich man, before the Kaaterskill was

constructed, together with his family, was in the habit of spending his summers at the Mountain House. He was a very successful lawyer, and *immensely* wealthy; and whenever he went "outing," he wanted the best that money could buy. One day, while at the Mountain House, his daughter at dinner called for chicken. The waiter replied that they hadn't any that day; and the proprietor, when appealed to, settled the matter by saying that they would not go to the trouble of cooking *just one*—not even for the Queen of England, much less for the daughter of lawyer—. Much aggrieved and insulted, as she thought, she related the circumstances to her father, and he likewise became angry, and had some words with the proprietor of the Mountain House. The result of it was, we are told that he took a stroll among the mountains that afternoon. He selected a spot upon which to build a hotel that would leave the Mountain House and every thing like it far in the shade. He purchased a large tract of mountain country; and although it was still late, he announced that, before another season, he would have a hotel up and ready for the occupancy of guests. There was no railroad there then; and during the bitter winter, workmen nearly 3000 feet above the level of the Hudson Valley, constructed what is now known as the Kaaterskill Hotel. Timbers, etc., were hauled up by wagons, at an enormous expense, and carpenters had to be paid double wages, in order to be induced to work in such bitter cold. The result was, the building was constructed and ready on time.

I do not remember exactly now, but I think their rates were from twenty to forty dollars a week. Single articles that cost in most places 5 cents were sold for 25. The wealth of New York city pours in, and seems to delight in paying 25 cents for something that ordinarily costs only 5. I believe it was only during the past season that the hotel was made to pay expenses. I was told that enormous quantities of leavings from the table are wasted. For instance, if a leg or wing of a turkey is cut off and not used for a certain meal, turkey and all is thrown away. This may be exaggeration; but there is no doubt that there is an enormous amount of stuff wasted.

The proprietor of the Kaaterskill, when he built this hotel, did so with the intention of running out the proprietor of the Mountain House. He would have every thing so magnificent in its appointments that no one would patronize his rival; but the result showed, as it *does every time*, that his rival did a bigger business than he ever did before. The manner in which the Kaaterskill was advertised and boomed drew people. Those of more moderate means, instead of patronizing it, went to the Mountain House.

A DOG STORY; HIS FLYING LEAP OVER THE FALLS.

After getting our party together we started our again for another point—the Kaaterskill Falls. The funny thing about it is, that they are, to a certain extent, artificial. They dam the water up at the height of 1500 feet, and when a lot of people are there to look on they open the gate and let the water fall, and thousands of people go to see it. We then clambered down and down, until we were half way down the gorge. We waited and waited for the water to fall. A small quantity was running over, but we waited in vain for a big onslaught. There had been so many visitors that day, that they had used up all the water. While we stood down by the bottom looking up, Mr. Coe told us of a little incident. The owner of a handsome and valuable dog had left his animal at the top

of the cliff, overlooking the falls. The man had gone down the same path that we had; and on looking up he saw his dog. He called to him; and the faithful animal, in obedience to what he supposed was his master's wish, and having entire faith that he would ask him to do nothing that would be to his peril, leaped from the height and was dashed to pieces on the rocks below, greatly to the consternation of the owner, and all who witnessed the affair. As we passed up the pathway there was a stone, and on it was a little epitaph telling the circumstances.

After taking in a few more objects of interest, which I have not now time to mention, we started for the hotel, which we reached toward evening.

[To be continued.]

ANOTHER LARGE ARTESIAN WELL.

THIS TIME AT A PLACE WHERE IT WAS GREATLY NEEDED.

Friend Root:—This (Indian) agency has been located on these grounds, $2\frac{1}{2}$ miles from the Missouri River, 20 or more years. It is situated on the bluff overlooking the river bottom. The muddy river, the sewer into which every thing in a large area of the Northwest drains, has been the only sure water supply for the agency during all these years. Wells have been sunk in various places 80 or more feet deep, without becoming profitable. Cisterns have been completed at the residences all over the village, but it does not rain enough here to fill them, and people have been compelled to buy water, hauled from the river at the rate of 35 cents per barrel. All the Indian agents have tried so hard to save money for the government, and thus increase their popularity in Washington, that they feared to ask for authority and funds with which to drill an artesian well, until during the last (official) days of Major Hill, when the necessary provision was made, and we now have a magnificent flow of water through a six-inch pipe, the lower end of which is 700 feet below the surface. The water has a pressure of 95 lbs. to the square inch; and when allowed to escape through a $1\frac{1}{4}$ -inch hole in a cap screwed on top of the pipe, it is forced upward through a stiff breeze and lost in spray, in which the prettiest rainbows sometimes appear, 70 and 80 feet above the earth. More than 100,000 barrels flow each 24 hours.

This well was drilled through a sort of blue slate and sandstone most of its depth. When about 640 feet down, the sandstone was reached; and in it was found a little water. This water-bearing substance was reached at midnight, when all the people of the village were at rest. The machinery was promptly stopped, and the government bell was tolled until nearly everybody knew that water had been found. The pipe was next extended to the bottom of the hole, when the drill was started again. The porous, sandy substance into which the drill, weighing three-quarters of a ton, was plunged, yielded readily, and with every stroke the volume of water was increased, and so was its pressure, until the honeycombed sandstone was passed through, and the drill was suspended in the mysterious underground body of water. As the drill passed out of the sandstone, the water was full of snow-white sand, fine and sharp; and just here came up about half a gallon of charred wood. It was almost coal. I send you a sample by this mail.

Many water-courses in the United States, which are called creeks, and which furnish power for the movement of flouring-mills and

other machinery, do not afford as much water as is forced through this six-inch pipe. The water is as clear as crystal, and is the "hardest" water I ever saw. It is so hard that it is almost bitter. It can not be used for laundry purposes without first having been subjected to the reaction of chemicals.

There are many artesian wells in this part of the country, and many more are needed. It is believed that the same body of water furnishes the supply for all the wells near.

W. MCKAY DOUGAN.

Santee Agency, Neb., Oct. 10, 1890.

Thanks, friend D. Why not utilize these wells for driving machinery? After the force of the water is spent it will be worth just as much for irrigation. Below is something more in regard to the artesian well which we pictured in our Oct. 1st issue:

I was somewhat surprised to see the artesian well in GLEANINGS. It is a good picture. You ask how deep they have to go for the artesian wells. There are eight between here and Woonsocket, and I believe the shallowest one is 600 ft., and they strike them all the way to 1000. There is no trouble in finding them anywhere in the James River Valley, which is about 100 miles wide; and all up and down the river they are trying for one. In Madison they are down 720 ft. now.

Winfred, S. Dak., Oct. 14.

J. W. CHAPIN.

There, friend C., that is just about what I expected—that is, that the whole region round about there would be tested, and this wonderful vein of water fully developed. Now, I am a great fellow to ask questions. What occurs to me just now is this: In the oil-fields they drill a great many dry wells—that is, wells that give nothing, and at the same time a vein may be struck giving a wonderful flow with these dry wells all around it. Is it so with artesian wells? My impression is, that, where this enormous pressure exists, the water would rise pretty much the same way anywhere in the vicinity, by going the same depth. If I understand you, there is a track 100 miles wide and of indefinite length, where artesian wells are found almost invariably, by boring deep enough.

GOVERNMENT IMPORTING BEES.

A VALUABLE SUGGESTION.

Mr. Editor:—You are aware that we have received great advantage from the discovery and importation of superior bees into America. Possibly there are bees in Africa, India, Ceylon, Philippine Islands, etc., that are superior to our present bees—even to Italians, Syrians, or Carniolans. We should at least know whether there are such bees, and should have a chance to test them. I have had some communication with government officials, and I believe that, if bee-keepers will move in the matter, we can secure such bees, and at no expense to the bee-keepers, and at slight expense to the government. It is certainly an enterprise worthy a trial.

It is suggested to me, that, if the bee-keepers will memorialize the government, through the secretary of agriculture, it will help to secure the object desired. Please bring the matter up in GLEANINGS for Nov. 1, which I hope may be out prior to the Keokuk meeting, so the bee-

keepers may have opportunity to consider it before it is brought up. I have written to the president, asking him to present the matter. The Central Michigan Association passed resolutions respecting the matter at their meeting yesterday. I shall also bring the matter up at our State meeting, at Detroit, Jan. 1, 1891. This is certainly just the kind of work that government can and ought to do. I hope other States will also resolve and send resolutions to Secretary Rusk. If we all move it will be done.

A. J. COOK.

Agricultural College, Mich., Oct. 17.

Well, friend C., if there be any better race of bees on the face of the earth than those we have already, we want them, sure. Friends Jones and Benton, however, seem to have decided pretty well that there is nothing much superior to Italians. Our missionaries in foreign fields will be great aids in this matter.

RAMBLE NO. 31.

JAPANESE BUCKWHEAT IN WESTERN NEW YORK.

We found in many of the counties in Western New York, that farmers were generally sowing Japanese buckwheat, and were giving it a high recommendation, both as to productiveness and quantity and quality of the flour. It was being introduced largely in localities where but little buckwheat had been previously sown, and beekeepers were accordingly rejoicing at the prospect of a fall yield of honey where they had none before. But in Chemung Co. we heard the first adverse report. An old farmer with whom we were riding said it might yield well, but a bushel of it did not produce as much flour as a bushel of the old kind, and he shouldn't sow any more of it; but further inquiry revealed the fact that the mill was to blame. The huller, we believe, would not allow the large kernels to go through; but with a proper apparatus, which had to be used on the new buckwheat, it was as productive of flour as of seed. We presume, however, that this old man and some of his neighbors will refuse to be benefited by the new-fangled grain. Japanese buckwheat has evidently come to stay until something better is found.

From Chemung we pass into Schuyler Co., in which is located Watkins Glen, famous for its wild scenery, and a place of summer resort. We greatly desired to feast our eyes on the actual features of the glen we had so often seen in photographs; but heavy freshets had recently been making sport with bridges, stairs, and ladders, and a general cleaning-out was the result, and the Rambler had to content himself by merely seeing where the glen was located, and imagining the rest.

The waters that come rushing down through these rocky clefts soon find a peaceful resting-place in the bosom of Seneca Lake, another of those beautiful sheets of water found in Western New York. One characteristic of this lake is its freedom from freezing. Its surface is scarcely ever covered with ice. On both sides of the lake are fertile farms. Vineyards are becoming quite numerous, and small fruits of all kinds are largely grown. Black caps were taking preference as a berry. What can not be sold fresh from the bushes, are put through the evaporator.

RENDERING WAX ON A LARGE SCALE.

On the line of our travels through Chemung and adjoining counties we found but little in-

terest in bees. Our cousin Nat, however, had a friend who was quite an extensive bee-keeper, having 250 colonies, and who had lost about 100, and didn't want his name to appear in print; but as he was getting out beeswax on a scale never before witnessed by the Rambler, he had no objection to our describing his method.

MELTING AND PRESSING BEESWAX.

About 1400 combs had been cut from the frames, and were piled up in the cellar. The oldest and most uneven had been weeded out, and were ready for operations. A large iron kettle, of over forty gallons capacity, was hung to a stout pole and crotched sticks with a log chain, and a rousing fire started. Two hundred combs, about the size of an L. comb, were gradually put into the kettle. In less than an hour the mass was seething and foaming in fine style. With a hoe, our bee-man kept agitating it until every lump was melted. Near the kettle was a press after the pattern of A. C. Hatch's, page 492, 1889, only a little more so. The forms of this press were perforated all around, and were left on to supplant the burlap. The contents of the kettle were transferred to the forms, and built up in cider-press style, with racks between the forms. Pressure was then applied with a common bench-screw; and, how the wax did hasten out! The hot liquid was run into a deep wooden tank; and, when nearly full, a plug was withdrawn from the bottom, and the water drawn off. When no more liquid would run from the press, and the water drawn from the bottom, the pure wax was run into square wooden boxes, making cakes of about 50 lbs., and nice shape to ship. Four runs could be easily made in a day, as our modest friend termed it, and over 200 lbs. of wax rendered; 3% combs would render out a pound of wax, and the dross seemed to be entirely free from wax. Our friend was enthusiastic over the rapidity of the big-kettle plan, and regarded steam and solar extractors as mere toys. "Then," said he, "I have learned something about the nature of the waste. I had a big pile of four of five bushels; and after it became dry I happened to put a chunk in the fire, and it burned a long time. I then raked the whole pile into the fire, and, how it did burn! It kept burning nearly all day. At night it looked like a pile of white ashes, and I supposed it was burned out. Five days after, I noticed the pile again, and it was much smaller; and upon thrusting a stick into it, the center was still live coals. That night, rain put it out. Had it not been for the rain it would have kept fire several days more. Then," said he, "Mr. Rambler, I find this big kettle makes a splendid outdoor feeder. I put in 200 or 300 lbs. of honey or syrup, and put a moder-

ate layer of grass on top; and, just see how the bees will go for it! Why, sir, it is inspiring. Every hive is represented in working up the

KETTLE OUTDOOR FEEDER.

bonanza; and after they get settled down to business there is no effort to rob other hives; and when they get through, all is quiet again. They get away with a power of feed in a day."

We hope the photo will give a realizing idea of the scene. When promiscuous or general feeding is desired, our friend's plan will doubtless recommend itself to the fraternity as well as to the

RAMBLER.

You are right, friend R. Japanese buckwheat seems to be all the rage among the farmers and bee-keepers in New York State. Wherever I visited, and from whatever sources I could gather, the yield, both in size of grain and quantity, has been so superior that next year they will raise nothing else.

Say, didn't your cousin's friend have more or less trouble with robbers entering in and around the kettle of melting wax? In our apiary we would have a scene very much like the one shown, where the bees are being fed as above. It would not matter very much whether it was melted wax or syrup—there would be a perfect hubbub and uproar; but perhaps he does it on a cool or rainy day when the bees would not fly very much any way. Almost all our wax-melting has to be done on such days.

FIXED FRAMES.

A DEMAND FOR SOMETHING THAT CAN BE USED ON OLD FRAMES.

It seems we are feeling around for some kind of a spacer arrangement for our frames. We are beating about the bush for something new, while I suppose we have the very thing we are looking for, if we would only lay our prejudice aside and use it. Any thing which will space the top-bars only will not do, for the whole frame must be rigidly fixed if exact spacing is necessary. I am inclined to think some kind of a closed-end-bar frame, or the Hoffman frame, or something on that order, is about the only thing that will entirely fill the bill. I hope you veterans will throw away all your prejudice, and give us something in that line that we can change to without too much cost.

A great many of us are using your Simplicity hive, frame, extractor, surplus arrangements, etc.; and while we might gradually change our frames, yet we can't very well change every thing.

Ernest's notes are eye-openers to many of us. I wish some of our friends who use closed-end frames would write and give us their advantages. I think we have heard of their disadvantages.

J. H. HILL.

Venice, Fla., Sept. 29.

We are very glad to inform you that we have something for just such bee-keepers as yourself, and you form a very large class. The following will just about hit you:

A CHEAP WAY OF MAKING THE HOFFMAN FRAME OUT OF FRAMES ALREADY IN USE.

Here is another modification of the Hoffman frame. Tack one piece on each end-bar, on opposite sides of the frame. They don't cost much, and are easily taken off when you get tired of spacers.

J. F. MCINTYRE.

Fillmore, Cal., Sept. 12.

The idea is not entirely new, as you will find it already mentioned and diagramed on page 425 of current volume. There is this difference: You would use it wedge-shaped and beveled at the top as well as at the bottom. In my *opinion* it is the best spacer for the hanging frames *already in use*. It is very cheap, and can be easily discarded if not justified by tests. It should be understood that this is not a real Hoffman, because the top-bar is not widened out at the ends. This latter the inventor regards as a very important feature. So if you discard the one above illustrated, it does not necessarily signify that you would the Hoffman, for a similar reason.

E. R.

HONEY CANDYING.

POLLEN ON THE BEES' BACKS.

In your foot-notes to friend Cleveland's article, page 714, you say that certain kinds of nectar will candy very soon after being gathered. My experience, running through several years, is that *any* kind of nectar will granulate under certain conditions. Friend C. says that lots of his made sugar before being capped over. My honey did the same thing, but not till we had cool wet weather. In 1885 it was wet and cool pretty much all summer, and the honey would granulate as fast as the bees gathered it. This is my reason for saying that all kinds of honey will granulate. If the weather is warm and dry while being gathered, and remains so till it is thoroughly ripened and sealed, in my opinion it will rarely ever candy. I do not remember having ever seen any sourwood honey granulated. I wonder if it is not owing to the acid nature of the tree. The aster honey will granulate as soon as extracted, owing, I suppose, to the cool fall weather in which it is gathered.

As to pollen on the backs of the bees, it is peculiar here only to the cotton-bloom. We know when cotton honey is coming in, by the yellow dusty appearance of the bees' backs. I think this is appropriated by the hive bees, as it is gone from the bees' backs when they come out

for another trip. This accumulation on the back is accidental, of course, as it is not the proper place to carry pollen. Bees are wise creatures, and take advantage of circumstances to advance their ends.

A. L. BEACH.

Pineville, N. C., Oct. 11.

Friend B., your suggestion is something I have not thought of before. You may be right; and since you have turned our attention to it, our readers can doubtless give us facts enough to decide the matter pretty soon. If it be true, the present season should be a very bad one for liquid honey. We still have customers who insist on returning honey as soon as it candies, and no amount of explanation helps the matter. Such people will have to have a grade of honey like the California sage, that does not candy.

I do not know. She is just as good as she can be both years, if her surroundings are favorable; and I have had them do a business the third and even the fourth year, of which I was proud.

Michigan. S. W.

JAMES HEDDON.

I have not conducted experiments carefully and painstaking enough to answer this query as it should be; but I think that, if given my choice when buying bees, I should take colonies with queens one year old in preference to those that were older.

Wisconsin. S. W.

S. I. FREEBORN.

In her second year. A man with good constitution may live to fourscore or upward, and he is in his prime from 40 to 50. A good horse, well taken care of, may live to be 30, and be in its prime from 12 to 15. The history of race-horses proves this. A good queen may live four years. She is in her prime in the second year.

Illinois. N. W. C.

MRS. L. HARRISON.

I should say, in the second year. I have also had queens do wonderful things in the third year. I think this point as to the value of a queen is not fully settled. Many queens will do equally well for three seasons; others will be superseded in one, and both bred under the most favorable circumstances.

New York. E.

RAMBLER.

QUESTION 171. *Is a queen at her best in her first or second year?*

Yes, both.

Ohio. N. W.

A. B. MASON.

In her first full season of egg-laying.

Illinois. N. C.

J. A. GREEN.

Her first full season averages the best with us.

New York. C.

P. H. ELWOOD.

In her second year, to the best of my judgment.

Ohio. S. W.

C. F. MUTH.

If hatched in July or August, her next season is her best.

Vermont. N. W.

A. E. MANUM.

I should say they average equally well both years.

California. S.

R. WILKIN.

I should think the first season after her first winter.

Wisconsin. S. W.

E. FRANCE.

I doubt whether there is any difference, but I may be mistaken.

Illinois. N.

C. C. MILLER.

First, always. They may, and usually do, last two years.

Michigan. C.

A. J. COOK.

Generally, good queens are as good the second and third year as the first.

Illinois. N. W.

DADANT & SON.

I consider the first year of the queen's life the most valuable, all things considered.

Ohio. N. W.

H. R. BOARDMAN.

I rather incline to the opinion that a very early queen is at her best the first season; but I do not feel much confidence about the matter.

Ohio. N. W.

E. E. HASTY.

That depends. I have had queens that were at their best when two months old, and others when three years old. It is needless for me to say that the latter were the most profitable queens to have.

New York. C.

G. M. DOOLITTLE.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

CHICKENS AND BEES MUTUAL ENEMIES: HENS TELL DRONES FROM WORKERS.

Friend Root:—In GLEANINGS for Oct. 1, page 707, you say that you have never known bees to sting chickens. I had seven colonies become queenless. Six of these were inside the chicken-yard, and only one outside. I lay the cause of losing so many queens, to the chickens. My wife blames the bees for the loss of so many of her little chicks. The bees not only stung the little chaps, but they also tried hard to sting the old ones. They did not succeed very well, as too many feathers were in the way. The hens do not appreciate the attack very much, I judge, from the way they fly around to get rid of them. They finally locate the bee on them, pick it off quickly, and in most cases the result is a dead bee, and they then proceed to eat it; but before they do that they pick it pretty thoroughly. Now, these hens are very cute in

the drone season. They have learned to distinguish between drones and workers. They will take their stand close to and at one side of the entrance of the hive; and when the drone emerges from the hive, and takes wing, the chickens take him in while he is on the wing, and that is the last of him; and when the workers get a little too thick around them they retreat to the back part of the hive, and further if pursued by the bees. In a very short time they are back again, take in another drone, and get back out of the way. All these performances I have seen. I have thought it is a good thing to keep chickens in the bee-yard to pick up all kinds of bugs, and to keep grass and weeds down, which they effectually do. Nothing green grows there except trees and grapevines; but if these chickens are guilty of killing and eating queens when going out or coming in from their wedding-tour, we shall have to separate them. A. W. AUSENBAUM.

Grant Park, Ill., Oct. 8.

Well, friend A., having chickens taught to pick out the drones is a good idea. Why are they not cheaper than drone-traps?

SOFT WATER VERSUS HARD WATER FOR BEES.

I see by your answer, p. 713. I was not explicit enough about the bees and the well. The water is soft—the only well of soft water in the town. I have a well of hard water right near the bees, and have kept water in a trough all the time. The neighbors emptied their trough, and the bees went into the pump and were pumped up by the handful. During the dry season they went there by the thousands. They stung the stock and the people going to the well. The owner thinks I ought to move my bees. I never tried fixing a place with pebbles and moss. I will try it. JOHN BURR.

Braceville, Ill., Oct. 5.

Well, friend B., you have given us a new idea—that bees prefer soft water to hard; but even if they do, I think it is a compliment to their good sense and taste. But you have struck on something else that interests me: Why should this one well be soft and all the rest hard? Is it not because it was drilled deeper? If so, perhaps some of the rest of you had better go down to this same soft-water-bearing stratum.

SUCCESSFUL BEE-HUNTING: 5 BEE-TREES AND 100 LBS. OF HONEY.

One week ago, after dinner I took a notion to cut a bee-tree, without veil or smoker. A neighbor, Mr. Richardson, said he would smoke them while I did the chopping and took honey. I cut the tree, and was opening the same, and bees were fighting like mad, when, who should come but the mail-man with the veil and smoker I had ordered. As the tree was on the road, I filled the smoker and put on the veil with much pleasure. I expected to get very little honey, but we took 38 lbs. of as nice honey as usually comes out of a frame hive. The Monday following I cut another and got 20 lbs. of fair honey. I have now got 5 colonies, all in good frame hives made by myself. First swarm are hybrids, some of them are beauties. The queen is a beauty. She must have come from Mr. Adam Bradford's, a patron of yours, some 12 to 14 miles from here, as he is the only one having any station in this section. Blacks are the rule here. Some 30 days ago a man seven or eight miles from me had found 39 bee-trees; another, 15; Mr. Winslow, 4; Mr. Kennedy and Roberts, one or two; myself, 5. The woods are full of them. Out of the five trees I think we took over

100 lbs. of honey. I am much pleased with the tools and GLEANINGS, as I am a Buckeye myself. M. R. SCUDDER.

Grandview Ranch, Tex., Oct. 4, 1890.

Why friend S., you must have a wonderful locality for bees. I am very glad your smoker and veil came to hand so opportunely.

ITALIANS AHEAD FOR WINTERING AND HONEY.

The past winter developed a point of superiority in Italian bees that was not known to me previously in wintering in chaff-protected hives. During the changeable and warm weather they remained clustered quietly, and so consumed less honey, and in the spring were well supplied with honey, while hybrids had to be fed, and many of my neighbors' black bees starved. Our season has not been very good. The Italians are far ahead of the blacks, though, and give 40 lbs. per colony of white honey as against nothing from blacks, and the fall crop yet to extract. Payson, Ill., Sept. 17. D. E. ROBBINS.

Your testimony is like hundreds of others we have received. Where we receive one report where the blacks did better, we receive ten others for the Italian superiority.

THE SUFFERING IN IRELAND.

Dear Sir:—You state in GLEANINGS, that you gave twenty-five hundred dollars to help a railroad. What will you give, and what effort will you use to induce others to give from that which God has permitted them to retain for their own comfort, to keep the people of Ireland from suffering the misery of starvation? I trust we shall hear from you in this matter.

Oct. 13.

A SUBSCRIBER.

My good friend, there are a few things in the above that I wish to take exceptions to. The first is, you do not sign your name. You may not have so intended, but there *seems* to be a disposition to find fault, and perhaps to question a little my Christianity. But why in the world do you not stand up and speak out like a man, and let folks know who you are? Sending a communication to an editor or anybody else (without giving at least the *editor* your name) seems to me like throwing a stone and then dodging behind a tree instead of letting your opponent see who it is that takes exception to your course of action. Many people, however, send anonymous letters, without thinking; but no true man or woman ever ought, under any circumstances, to be guilty of such an act. I wish it might be done away with. Again, you say that I gave *twenty-five hundred dollars* to help the railroad. In one sense this is true; but as you put it, I think it conveys a wrong impression. Until the present day we have been at the mercy of a single railroad line. This line moves freight only twice a day; and where goods are urgently needed, if they fail to go by the morning train they must lie in the depot, even if the consignee is suffering, *a whole day*. Another thing, we have never had an *east and west* railroad. All our goods have been going either north or south, until they could find some east and west line. Now, the money I have agreed to pay is not only to help the railroad, but still more to help *you* and all

the other friends who favor us with their orders. I subscribed the amount mentioned, because I felt it was a just debt I owed to those who gave me their patronage.

Now, then, for our neighbors across the water. As the writer of the above has not told us how to give, I shall have to ask some reader of GLEANINGS to give us the address of an organized society or company who will take our money and send it quickly and safely to those who are suffering. I am sure the GLEANINGS family will do their part. If there is a subscription being raised in your community, hand over yours, and do not wait for GLEANINGS. I asked a friend how it was that Queen Victoria did not bestir herself to supply the suffering of her subjects. We all know that the British Isles are abundantly able, if any nation on the earth is. The reply was, that the wealthy landholders were, on the contrary, turning the poorer classes *out of doors* because they could not pay their rent. I really hope that somebody may be able to tell us that this is not so. As GLEANINGS goes to both England and Ireland, some of the good friends there can, without question, enlighten us. Will the editors of our English bee-journals tell us about it, and tell us where to take hold and help? With the means of communication, and facilities for transportation, there ought not to be any *starving human beings* anywhere on the face of the earth. After dictating the above, our short-hand writer gives the following figures, which may have some bearing on the matter. They were used on large posters here during a temperance campaign. But even if this be true, the women and children ought not to be allowed to suffer.

During the Irish famine of 1878, \$6,000,000 was sent to her relief from other nations; but during this same year the whisky-bill of Ireland was \$42,000,000.

Add to this amount the sum paid for tobacco, which is almost universally used by the Irish, and it is not much wonder that some people feel like saying to her as Hercules said to the man whose wagon was stuck in the mud: "Put your own shoulder to the wheel first, and then I shall know better how to help you myself."

SLATTED HONEY-BOARD A NUISANCE: THE QUEEN-EXCLUDING BOARD A SUCCESS.

The honey season was better here. I got almost 500 lbs. extracted honey from my eleven best hives. Your slatted honey-board is a nuisance for extracted honey down here. Brood gets scattered all over the hive. The queen-excluding zinc honey-board, however, works like a charm. It keeps the queen down, and then the bees make the combs much thicker, so that I have only 8 frames in the upper story of regular Simplicity bodies. This saves bees the trouble of capping, and me that of uncapping two frames to the hive.

TO PREVENT BRACE-COMBS.

I tacked inch-wide strips of tin on both sides of top-bar, level with the same on top. This proved an entire success—not one bit of brace-

comb. I also tried the double top-bar with the same result, only the latter is more troublesome to make.

BEE-ESCAPES; THE REGULAR CONE THE BEST.

I tried both the horizontal and the regular cone bee-escape; but instead of using them in boards I fastened them to a piece of enamel cloth, wide enough to project over the sides of the hive, enamel side down. They worked best when I did not fill the new upper story with empty comb, but put only one or two combs on each side. Wherever I put in the whole set of empty combs it seems the bees formed a cluster above and below the escape instead of moving downward. Of the two bee-escapes, the regular cone worked to better advantage than the horizontal. I never tried to extract before I had left the escape on a night. Whenever there was any brood in the upper story (which was invariably the case until I kicked out your slatted honey-boards), the escape did not work at all. When there was no brood they worked to my satisfaction, only very few bees remaining, which soon found home from the extracting-room.

J. C. RIEGER.

Brenham, Tex., Aug. 18, 1890.

GETTING BEES TO TAKE DOWN THE HONEY: MASON FRUIT-JARS FOR FEEDERS.

Your answer to W. R. Tate, page 716, is different from what my answer would be. I would put on an empty upper story, then another upper story on top of that one, with combs uncapped in it; and if the bees are in need of stores they will carry it down immediately. I know this by practical experience. I have been feeding quite a good deal that way lately; and another way I am feeding extracted honey is, to put the honey into quart cans and leave the tops partly screwed on, and lay it in an empty upper story, on its side, and the honey will run out about as fast as the bees will take it. This is a very easy, cheap, and clean way to feed.

M. F. BACHELDER.

Alamo, Mich., Oct. 6, 1890.

You are doubtless right, friend B. Our remarks applied to the two-story chaff hive which we have been trying in that way. You can't tier the two-story chaff hive to three stories high. The idea of using ordinary Mason fruit-cans for feeders is good, and will save to many of our readers the expense of special feeders.

SOUR SMELL PROCEEDING FROM THE HIVE.

Can you tell me why there is a sour smell from some of my hives, something like the odor of soured honey? The colonies from which it comes seems healthy, and the odor is not apparent when the hive is opened. The apiary is on a side hill, and well drained.

Oronoque, Conn., Oct. 2. F. W. HUMPHRY.

Friend H., the smell you mention probably proceeds from a certain kind of fall flower. The matter has come up several times in past seasons, and, if I remember correctly, a certain kind of aster gives off this aroma when freshly gathered. It will entirely disappear when honey is well ripened, and you need have no apprehension in regard to it.

THE OUTSIDE WINTERING SHELL FOR THE DOVETAILED HIVE.

I wintered two nuclei of about three or three and a half frames each, in 8-frame Dovetailed hives, by making an outside shell all around the hive, with a four-inch space at the sides and

ends, and about 8 on top, filled with dry pine sawdust. In May I bought a colony of about 7 or 8 frames, with queen, and lost a good many in transferring.

E. P. CRANSTON.

Keating, Ore., Sept. 25, 1890.

Friend C., you can succeed, ordinarily, with even three or four frame nuclei, where packed as you suggest. But should you undertake to winter weak colonies in this way on a large scale, you would probably lose a good many where we have a winter of ordinary severity.

FEEDING BACK: ONE WHO HAS PRACTICED IT 12 YEARS.

The season has been one of the best. One man took 300 lbs. of extracted honey from each of two of his best colonies. He runs for extracted honey, then feeds back. He has practiced that for over 12 years. He keeps from 15 to 40 colonies. He is an extensive contractor, or more would be kept. I told him yesterday he was the only one who made feeding back a success.

CHANGING QUEENS DURING THE HONEY-FLOW.

We have only white clover this year. The season was poor from May 25 to July 1. My crop is 850 lbs. from 22 colonies, spring count. I increased to 28. I removed half the queens from May 28 to June 5. I tried to get a young laying queen by June 15, but failed. I missed a cell in some, and in others they started cells on very old comb, so many swarmed out. But they invariably swarmed out in the afternoon of the day before the young queen came. Of course, they returned then. Should we have a rainy day it would break the rule. I never saw that in print, or noticed it in colonies that had swarmed and cast a second. I suppose, as they were kept at home so long, they were so anxious to take a trial flight. Three failed to swarm at all that had queens. I am satisfied with the system and the honey produced. It is regular, and very fine in appearance.

SELLING SECTIONS BY THE PIECE INSTEAD OF BY THE POUND.

Pottstown has nearly 15,000 people, and over fifty grocers. One man sells by weight; the forty-nine sell sections of honey by the piece. The man that sells by weight sold No. 1 honey from Muscatine, Iowa, for 11 cts. per section last spring. He is no profit to the bee-men, because he beats down prices.

About six or eight of my hives had about 45 lbs. in the brood-nest at the end of the harvest, or my crop would have been 1000 lbs. Several I contracted to five combs, then I got it all without a queen in the hive.

W. W. KULP.

Pottstown, Pa., Sept. 4.

Friend K., it is possible that the man you mention makes a success by feeding back, providing he does it only to finish up sections partly filled, providing he also gets a large price for comb honey and a comparatively small one for extracted. At the present time there is quite a wide difference in the market, nice comb honey bringing very nearly if not quite double the price of the liquid. If only one man out of fifty in Pittston sells honey by weight, I do not know but that I shall have to give up; but it is something that I had hardly ever heard of when the matter was first mentioned. I am sure there are very few places in our State where sections are sold by the piece. Now, if this is going to be the rule, we as bee-keepers ought to do all we can to have our sections uni-

form in weight. I know that, in many places, there is a growing disposition to get rid of pennies, and I do not know but that this is the right thing to do. A few days ago I told our wagon man to reduce the price of the small sugar pumpkins to half a cent a pound. He said, after a while, however, that it was too small business, and that people were just as well satisfied if we told them that the pumpkins were 5 cts. for the small ones and 10 cts. for the large ones. I have many times thought that the time is coming when we can not afford to waste time over pennies. The five and ten cent counters, you know, have been a move in the right direction. Quite a few berry-growers have written me that they are obliged to sell berries for either 10 cts. a quart or 15—that people would not have any half way about it. In fact, we are coming to this a great deal ourselves. We use pint boxes altogether for berries, and sell them at either 5 cts. a box or two boxes for 15 cts. For very choice berries we sometimes get 10 cts. a pint. Now, in view of this, our honey should be put up in such quantities as to be sold at 10, 15, or 20 cts. a package. Perhaps the very thin ones or flat ones had better be sorted out. If a customer wants two sections, he might be given a thick and a thin one, so as to make it fair.

MORE ABOUT WATERING-PLACES FOR BEES.

In answer to the inquiry of John Burr, page 713, I will say that, three years ago, when there was no prospect of a honey crop, I rented a large farm, and went to raising other crops. On the farm was a large artificial pond; and whenever the bees had occasion to carry water they went to the pond for it, the soft mud being at times almost covered with the striped Italians. They bothered nowhere else. This summer they were so thick around my watering-trough that on some days the animals could not be induced to approach the trough until the bees had retired in the evening. We also had a small out-apiary near a road that is much used. At the road was a well and trough. The bees troubled the neighbors very much, and attacked a team that had stopped for water. The team ran away, and the occupant (a woman) was considerably hurt. Now, I have determined to construct a pond on my premises, for the bees to get water. The warm stagnant water seems to be just what they want.

CATFISH.

When on the farm, as already mentioned, I put some catfish spawn into the pond this season, and the occupants of the farm have been catching some of those "cats" a foot in length, and delicious as only catfish are. You see, I shall make my pond answer a double purpose. The pond will draw the bees from the well, and raise fish for the family, and the presence of the fish in the pond will prevent the water from becoming stagnant to a degree of unhealthfulness. Besides, I can arrange it so as to be a very convenient watering-place for my stock without allowing the stock to go into the pond.

Centerville, Ia., Oct. 4. G. B. REPLOGLE.

Friend R., within a little distance from our apiary is a pebbly brook, and in the summer time the water stands only in holes and hollows of the rocks a great part of the time. This creek is out of everybody's way, and it is often

so full of bees that the horses are afraid to cross the brook when cultivating. Perhaps others may make use of such brooks. Your remarks about catfish suggest something that I have not thought about before; namely, that carp-ponds are really a part of a bee-keeper's outfit. Our bees seldom go to the carp-pond, however, because the brook below it is so much handier.

KEENEY'S METHOD OF WIRING; USING TACKS INSTEAD OF WIRE NAILS.

I have been using the Hatch plan of wiring frames, as given on page 561, and I have found something I like better than either staples or wire nails to fasten the wire on. It is 14-oz. Swede-iron tacks. Drive the tack about $\frac{3}{8}$ of its depth in the $\frac{3}{8}$ -inch end-bar, placing them in the same position that Mr. Hatch does the staples or wire nails. Take spool wire (not coil), and run the wire the same as he does, leaving all wires loose except those running from 2 to 3 and 4 to 1; draw those tight. After the wire is on, stand four frames on end, and drive the tacks home, or until the wires are drawn as tight as you like them. I find the wire will break every time before the tack will pull out. The advantage over staples is, one can work much faster, and no waste of wire; and over the wire nails you can draw your wires just where you want them. The wire should be wrapped two or three times around the tack, to make it hold well. If the above is of any use, give it to the bee-keepers.

Delavan, Wis., Aug. 11. F. E. BURROWS.

You can use tacks, but you are obliged to sacrifice the two side perpendicular wires, which we regard as so necessary. On this account we should much prefer the hooked wire nails.

CANDIED HONEY FOR WINTERING.

Will the bees winter safely on candied honey? If not, what can I do, not having any extra brood-combs? FRANK W. LIGHTON.

Williamsport, Pa., Sept. 14.

As a rule, bees will winter all right on candied honey; but sometimes, when it is candied very hard, as honey from special plants does at times, it seems some seasons the bees do not seem to get along so well with it. When the weather becomes very warm, however, say late in the spring, they will bring water and work it up. When there happens to be a dearth of bee-pasturage between fruit-blossoms and white clover, so that the bees need feeding, candy can be used to good advantage.

A GOOD REPORT FROM MRS. AXTELL.

Our bees are again nicely at work filling their hives with honey. We have strong hopes they will fill up for winter without having to feed. Our home apiary here on the prairie is getting more honey than the timber apiary, four miles away, although there is much more waste land in the vicinity of the timber apiary; but our bees at home always average more honey per colony, except early in the spring, when they get more from the trees. If we do not have to feed the honey taken from them in the spring, there will be fair returns for the men's labor upon them, and the pleasure I have had with them will repay me for my work. The bees come in heavy laden now. They look so big and heavy and yellow and soft and clumsy, like baby bees, that it is easy to handle them now.

What a delightful business this bee-keeping would be if they were storing honey the whole year round! Everybody then would be bee-keepers, and honey would be so cheap we could hardly give it away. MRS. L. C. AXTELL.

Roseville, Ill., Sept. 5.

WHAT I DO WITH PROPOLIS.

When my husband went into the bee-business, propolis used to be a source of trouble to me. If thrown on the ground, it stuck to the children's bare feet, and to every thing that came in contact with it. I now save it and use it to seal jars of fruit with. I have gooseberries, currants, and other fruit, put in jars. Any ordinary cover will do. Seal it well around with propolis, and it will keep well. MRS. BURR.

Braceville, Ill., July 25, 1890.

Well done, my good friend. I have insisted for long years that propolis must be good for *something*, and now you have hit it exactly. We all know that it will stick to tin, glass, or any thing else; but does it never get soft in very hot weather?

MILLER'S PLAN OF AN APIARY; FURTHER SUGGESTIONS.

Allow me to say, in reply to Ernest's comments on my article, page 524, July 15, that, after I had written the article, I concluded the distances I had allowed were too little, but thought I would not re-write it, as every one would be likely to make the distances to suit himself, if any should try the plan. I would allow ample space, yet not more than necessary, as this makes more work for the lawn-mower. I prefer to use a scythe to keep down the grass outside and around the apiary, as it does not need to be cut as often as that among the hives; and one accustomed to using a scythe can, with a good keen one, do a respectable job on a lawn.

QUEENS, LAYING OF.

Some time ago, in passing through the apiary I concluded to look at some young queens that had hatched in colonies that had cast swarms. The queens were some two or three weeks old. I opened a hive and found two, three, and sometimes four eggs in a cell. I was somewhat suspicious, and concluded to see what kind of a queen there was in the hive, if any. In a short time my eyes caught sight of her, one of the most beautiful queens I ever saw. I went to a second and third hive, and in all of them I found the same state of affairs. The colonies were strong, and from one of them, a one-story ten-frame hive, I had extracted 26 lbs. of honey a short time before. Those queens are all good, and I write this as a warning to beginners not to be too hasty in deciding that they have fertile workers or poor queens. S. E. MILLER.

Bluffton, Mo., Aug. 9.

DIED FROM A BEE-STING.

We inclose a clipping from the Syracuse Evening Herald, of Aug. 28. The doctor that lives next door to us says Mr. B. died from the shock. He says some people have died from the shock caused by having a tooth extracted.

Syracuse, N. Y., Aug. 28. F. A. SALISBURY.

La Fayette, Aug. 28.—The death of Alexander S. Baker yesterday occurred under very peculiar circumstances. He died from the effects of a small honey-bee sting, and within ten minutes after being stung. August 8th Mr. Baker was stung on the back of his neck and became unconscious, remaining in that condition for an hour or more. On Wednesday he was stung on the end of his nose, and the effect was similar to his first experience, and proved fatal.

Some years ago Mr. Baker kept an apiary and

nearly lost his life then by being stung. This was thirty-two years ago. He was very ill at that time, and since then his pulse has been as low as forty-five almost habitually. Five years ago he was stung with nearly the same effect.

On Wednesday Mr. Baker was in the garden at his farm picking beans when he was stung. He went into the house as hurriedly as possible, and told one of the members of the family what had happened, with the remark that he was sick at his stomach. Those were his last words. He died immediately. Dr. Morris, who was called, says in describing the case that Mr. Baker died from "constitutional susceptibility."

REPORTS ENCOURAGING.

FROM 18 TO 20 LBS. PER HIVE.

I am now taking off my honey. I am getting from 18 to 20 lbs. per hive—about a third of a crop. I have 19 colonies. F. BURR.

Braidwood, Ill., Sept. 20.

A NICE LOT OF HONEY.

There has been an abundance of white clover; also the flow of basswood was good, so that we have a nice lot of honey. Our bees have not worked on buckwheat. JOHN HERRICK.

Gerry, N. Y., Sept. 23.

BEES DOING SPLENDIDLY.

Bees here are doing well on buckwheat and heartsease. We had a fine crop of basswood, and indications are favorable for a good fall honey-flow. THEO. WALKER.

Denison, Ia., Aug. 30.

HONEY CROP EXCELLENT.

The honey crop is good in quality and fair in quantity. From 80 colonies I have taken 5000 lbs. of comb honey. This is the largest yield since I commenced bee-keeping.

Eddyville, N. Y., Sept. 22. C. H. AVARS.

HONEY CROP ABOUT AN AVERAGE.

Our honey crop will be about an average one. We shall get about 60 lbs. of surplus per hive. Very few bees swarmed, and are therefore very strong. J. L. GANDY.

Humboldt, Neb., Sept. 8.

14 TONS OF HONEY.

We have been in the business for 14 years. The bee-business goes well with our family. We extracted this year 14 tons of choice sage honey. California wild sage makes the best of honey. I have just returned from a trip through Colorado, hunting a market for honey and horses. Our home market for honey is very good, so we will sell at home. Our bees are mostly blacks. CHAS. LASALLE.

Lompoc, Cal., Sept. 12.

40 LBS. PER COLONY.

I noticed in the last GLEANINGS, Sept. 15th, that reports from this State are rather discouraging, so I send you my experience to partly balance it. Last spring I had three good colonies of Italians in the Root chaff hive. I now have seven colonies, and have taken 40 lbs. per colony of comb honey, mostly heartsease. Choice 1-lb. sections sell for 20 cts. per section. Bees are in splendid condition for winter.

J. E. LEYDA.

Weeping Water, Neb., Sept. 26, 1890.

UPWARD OF 200 LBS. PER COLONY.

This is a comparatively new country, therefore our bee-industry is young, light, and limited; but few of our own 50 colonies of bees, most

of which have done well with proper care. My bees have averaged upward of 200 lbs. of honey to the colony, and but slight increase of bees. My best record is 330 lbs. of strained honey, no increase. I shall try to beat that record next year. Bees are all in good condition for wintering. Average price of honey is 10 cts. per lb. Elsinore, Utah, Oct. 6. N. B. BALDWIN.

Well, friend B., that is pretty good for this season of poor reports. We should have been glad to know of the source of such a great crop of honey. I wonder if it is not the sweet clover that I wrote up after my visit to Utah.

ENCOURAGING FOR ASTERS.

Please identify the inclosed plants, white and purple. The bees are very busy on it, my scale here showing 3½ and 2 lbs. per day when the weather is favorable, and working only from 10 to 4. J. B. ENOS.

Connellsville, Pa., Oct. 8.

Well, friend E., that is a pretty good report—3½ lbs. a day as late as Oct. 8. We have been in the habit of taking it for granted that little if any honey is gathered as late as October, in our locality; but the fact you furnish encourages bee-keepers to be slow in deciding that all hope of a honey crop is at an end then.

STRAWBERRIES AND BEES.

I raised this year 944 qts. of strawberries on ¼ of an acre. Last year at this time, from seven colonies I got 950 lbs. of white-clover honey in 1-lb. sections; this year from 21, 320 lbs.

W. E. THOMPSON.

Laddonia, Mo., Aug. 23.

Why, friend T., you are an old "wheel-horse," to be sure, if you continue to make such good yields as you mention in the above, both in honey and in strawberries. Why didn't you squeeze out a few more quarts and make it a thousand from an eighth of an acre?

A GOOD REPORT.

I had an increase of 91. I extracted 22,130 lbs., and obtained, in 1-lb. sections, 1600 lbs. The bees are in good condition now.

Tropico, Cal., Sept. 19. J. J. COLE.

Well done, old friend; but you did not tell us how many colonies you had to commence with. I am exceedingly glad to know that you have really got a good thing in your California investment. I will explain to our readers, that friend Cole purchased an apiary at the foot of the mountains. I went over there to look at it, just about the time of the purchase. The ranch was supplied with water which came down from the mountains in—what do you suppose? Why, in cane fish-poles that grow plentifully in the neighborhood. The only drawback was, that the cayotes, or the prairie wolves, had discovered that they could get water by chewing up the fish-poles. As this saved them traveling half a mile or more, it became a favorite pastime. But, oh my! was it not vexatious to the proprietor? As the fall was considerable, when the canes were broken the water would frequently spout up in the air to a great height.

42,000 LBS. OF HONEY.

Our season is over. We have about half a crop; I got 28,000 lbs. of extracted honey; 14,000 lbs. of comb honey, and about 400 lbs. of beeswax. I have a 7-frame automatic extractor, and I have a double honey-tank holding seven tons and a half at one time; and a large solar extractor.

C. P. LANE.

Warthan, Cal., July 25.

NOTES AND QUERIES.

TWO BAD SEASONS.

The past two seasons have been very hard for bees in this vicinity. Mine have not made a pound of box honey this season. It has been the poorest but one for 25 years.

H. S. WEBBER.

Monroe Center, Me., Sept. 15.

BEES WORKING ON PARSNIP.

I saw in GLEANINGS of Oct. 1, page 713, about bees working on parsnip. I raised parsnip-seed in my garden, and the bees worked on it every pleasant day while in bloom. I think it a good honey-plant. We can find out another year.

Mrs. M. E. TANNER.

North Woodbury, Ct., Oct. 20.

900 LBS. FROM 21 STOCKS.

My honey crop for this poor season foots up over 900 lbs. in 1-lb. sections from 21 hives. Too late. Last-year swarms in gums are doing nothing above their living. As a general thing, among the old class of bee-keepers the honey crop has been a failure in these parts.

Pine Grove, O., Sept. 27. S. DANIELS.

AN INCREASE OF 10 COLONIES FROM A 3-FRAME NUCLEUS.

I received from you last September one three-frame nucleus, which wintered in good shape and increased this year to ten colonies, which are strong enough to winter all right; and extracted 155 lbs. of alfalfa honey.

Keating, Ore., Oct. 5. A. S. LOVE.

[You did well.]

CHANGING QUEENS.

This will not stop the nameless disease. I had five queens last year from St. Louis, and introduced them to my bees. They are affected by the disease, and they are worse now than before.

FRED A. HUND.

Casco, Mich., Oct. 6.

[Friend H., we hardly think the above is conclusive, for the queens you received may have been from colonies afflicted in a like manner. I think giving the stocks new queens from an apiary that never had the disease will put an end to it—at least, we have never known it to fail.]

ITALIANS ON GRAPES.

I find the Italian bees I bought this year surpass hybrids in one thing—they are always on hand where there is *any* chance. If a bee gets drowned in sorghum it is an Italian; while the grapes on our house-arbor, after the rains cracked them, were like a swarm, and all Italians. This was the first time I ever saw any havoc by bees to grapes.

W. N. ROOR.

Assumption, Ill., Oct. 6.

[I know this is true of the Italians, many times. Very often the Italians will be at work on red clover while the blacks are working on rotten fruit, and hanging around cider-mills.]

A STONE BUILDING FOR BEES.

How would you prepare the following building for wintering bees? I have a stone building 12 feet long, 10 wide, 8 high, with a common shingle roof, in which I wish to hive 35 colonies of bees, all in 8 and 10 frame Langstroth hives.

Mt. Horeb, Wis., Oct. 9.

E. C. ELVER.

[If your building is frost-proof, pile them up in rows without bottom-boards, a la Boardman, or as is explained in our latest A B C of Bee Culture. Stone buildings have not been found very successful—at least, so far as my experience goes. They are apt to be damp and cold, and they do not dry out as well as the sawdust-packed repositories.]

APPLE-TREES FOR SHADE.

I should like to be informed how much shade a swarm of bees will do the best under, through the summer season. Is the shade of large apple-trees too dense? I have some swarms standing directly under quite large apple-trees, where the sun shines on the fronts of the hives less than half the time.

A. P. FLETCHER.

Proctorsville, Vt., Aug. 31.

[Apple-trees, if not too large, and the foliage not too dense, form excellent shade for hives. A young orchard makes, therefore, a very nice place. For further particulars, see the A B C of Bee Culture.]

GETTING YOUNG PLANTS FROM STRAWBERRIES SET IN AUGUST.

The 24 Gandy strawberry-plants sent me Aug. 5th have sent out fifty runners, and the Haverland has sent out quite a number, all doing splendidly. I lost but one plant out of 96, and something cut the root of it. If the weather continues nice for three or four weeks, I shall get 100 sets from them.

P. M. BYERLY.

Farley, Ia., Sept. 10.

[Friend B., in our locality I think we could safely get double the number, with a favorable fall like the present one.]

WHEN TO MOVE A WHOLE APIARY 100 YARDS.

My bee-yard is within six feet of my dwelling, and within twenty feet of the public highway, with no obstruction intervening, save small fruit-trees, peach, quince, and pear. When I established it there I took no thought of increase. It now numbers over 20 stands. Should I live and retain my present and ever increasing interest I must remove them to a spot more remote from public travel. I desire to place them about 100 yards from their present location. Will you tell how to do it, and when?

Guys, Md., Sept. 29.

WM. S. ADAMS.

[Move this winter, after the bees have been confined for awhile.]

HOW TO MAKE GREEN-TOMATO PIE.

I wonder if the readers of GLEANINGS know that green tomatoes are excellent for pies. If you have never tried them, ask Mrs. R. to make one. Here is a recipe:

Prepare the tomatoes as you would apples. Take $\frac{3}{4}$ cup of sugar; 2 heaping teaspoons flour; stir sugar and flour together, and spread on the bottom crust; then add tomatoes and two table-spoons vinegar, and a little butter. Put on upper crust, and bake. Cut the pie into as many pieces as you wish. I think four is small enough.

S. H. HOUGH.

Saybrook, O., Sept. 16.

THE BOOK AND THE STRAWBERRIES.

The book on strawberries is at hand. Thanks. The strawberry-plants are all growing nicely, and it certainly is a delight to see

them grow. Haverlands and Gandies commenced throwing out runners right away, and starting new plants. I want to ask you one question: Will the mother-plant do to set out in the spring with the young plants, and cultivate according to instructions (that is, will she throw out runners) next summer?

Tatesville, Pa., Sept. 18. G. H. KNISLEY.

[Yes, but it is not considered as good.]

THE STING OF THE RED ANT OF TEXAS WORSE THAN THOSE OF A DOZEN BEES.

I notice in GLEANINGS, of Sept. 15, that Mr. Geo. E. Hailles, of Lytle, Tex., gives an account of red ants attacking his bees. Now, remember that was just after a rain, and in July, so the ants were swarming. They always swarm just after a rain. Red ants that live in the ground never bother bees. I have four or five ant-beds in my bee-yard. You seem surprised to hear that an ant-sting is worse than a bee-sting. That is because you are not acquainted with them. They are not nearly so large as a bee, but are all "pizen." I would rather be stung by a dozen bees at one time than one red ant. They are nearly as bad at hurting as a scorpion. If you have a remedy for exterminating red ants, please turn it loose in Texas. W. F. ELLIOTT.

Clio, Tex., Oct. 4, 1890.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

That art on which a thousand millions of men are dependent for their sustenance, and two hundred millions of men expend their daily toil, must be the most important of all—the parent and precursor of all other arts. In every country, then, and at every period, the investigation of the principles on which the rational practice of this art is founded ought to have commanded the principal attention of the greatest minds.

JAMES F. W. JOHNSTON.

OUR BEAUTIFUL FALL WEATHER.

At present writing, Oct. 25, we have not yet had a frost to injure lima beans and tomatoes—that is, up around the windmill they are uninjured. A frost injured some things a little on the lower grounds a few nights ago. There is something queer about the weather this fall. A great many times it has cleared off cold, and we have had every indication of a severe freeze; but before morning the temperature would let up, and the frost that started so fiercely the night before did not amount to much after all. We had the same state of affairs a year ago. Yesterday we had green peas for breakfast, both Stratagem and American Wonder, and I never ate sweeter or nicer peas in my life. For dinner we had Livingston's Gold Coin sweet corn. It is as yellow as old gold, and almost as sweet as any sweet corn, having at the same time a slight field-corn flavor. There has been quite a little discussion about the propriety of putting it in our forthcoming catalogue. The only difficulty is, that it increases the number of varieties of corn further than we want it. Tomatoes are still ripening slowly.

This year, whenever I put in a crop so late that I thought it might *possibly* have a chance to mature, we hit it just right; and so many things often hold out longer than we expect, I rather like the idea of sowing late crops, even if there are a good many chances for them to be a failure. We are still picking wax beans, and have a fine crop of Eclipse beets, about as large as hens' eggs. Cabbages are so plentiful we are offering them at half a cent a pound. Not so with cauliflower, however. There happens to be a scarcity, so we are getting 15 cents

per lb. for the handsomest Snowball cauliflower we ever raised. All insect enemies have vanished, and every thing in the cabbage and turnip tribe is growing with great luxuriance, unharmed by any insect foe. This is another advantage with late stuff. We have single stalks of White Plume celery weighing 3 lbs., and we are still getting 10 cts. per lb. for first class. Just think of it! 30 cts. for a single root of celery! The New Rose is growing finely, but it has not matured enough to use yet. We are now selling heads of Grand Rapids lettuce, weighing two or three pounds, at the low price of 5 cts. per lb. Beautiful parsnips bring 3 cts. per lb. Chinese Rose winter radish now "takes the cake" over every thing else. They are almost as mild as a very sweet turnip; and when first washed and put on the wagon, the delicate rose color makes them more attractive than any thing else in the radish line. They bring 10 cents per dozen radishes. Spinach is large enough to gather, but we have enough other stuff so that we do not need it. Our Hubbard squashes are all gathered, and stored in slatted potato-boxes, out of the way of the frost. We have beautiful Ignotum tomatoes on the table every day, gathered right from the field. Served with sugar and cream, I believe I like them fully as well as yellow peaches; and when peaches are so high that you have to pay 30 cents per lb. for evaporated ones, with the skins on, I tell you it is quite an item to have plenty of tomatoes out in the field. Every thing up on the hill by the windmill is so far uninjured by the frost; so you see that it pays a market-gardener to have a hill for late supplies, as well as to have a rich creek-bottom garden. We have the handsomest turnips that I ever saw or heard of. The Purple-top White Globe is still our favorite.

Now is the time to get ready your green-houses or cold-frames. Lettuce, beets, spinach, cabbage-plants for cold-frames, winter onions for use when the ground is frozen, rhubarb, radishes, etc., should be growing in beds, to be covered with glass later. I am decidedly in favor of movable glass of some shape or sort; and then I would leave the glass off just as long as possible without injury to the plants.

RAISING STRAWBERRIES JUST LIKE CORN.

Friend Root:—I've just finished reading the "A B C of Strawberry Growing," and it has stirred me all up. It's a good book, isn't it? How I wish the busy times of bees and strawberries didn't come together, that I might try my hand at it again, and see how much better I could do with the increased light!

The proportionate prices of land and labor make a good deal of difference as to the wisest plan of raising strawberries. If land is very high, and labor very cheap, then it may be best to use the single-hill plan, and persistently keep down all runners. On the contrary, if land is cheap and labor dear, the very reverse may be best. As this is the condition of things among many of your readers in the far West, it may be well to tell how I raised strawberries by the acre, years ago, on land that cost \$22 per acre, near a village. The ground was prepared exactly as for corn, and you must remember that, in some new countries, we have very rich land for corn. The land was marked as for corn, marking both ways, one plant set at each cross-mark, and then the ground was cultivated both ways, and the runners allowed to run and set at their own sweet will. As the runners naturally incline to spread in all directions, nothing better could be done than to let them alone. In addition to the cultivating, a little hoeing kept down the weeds, and in some places this might not be necessary on new ground.

Now, I don't say this is the best plan; but don't you think that many a farmer out West who thinks he can't fuss to raise strawberries might be induced to do so if he were told how little trouble would supply his table? Just tell him to set one corner of a corn-field to strawberry-plants, and cultivate them with the corn, the only difference being in setting the plants. Likely he may raise a question about mulching. Well, if that's going to scare him out of it, tell him I raised a paying crop without using any mulch whatever, and you know it's a good bit colder here than at Medina.

TRIMMING.

It may be presumptuous for one so much behind the times as I am, in matters horticultural, to suggest any addition to what has been said by two such experts as you and friend Terry. Nevertheless I know you'll let me "speak in meeting," and will good-naturedly set me right if I'm away off.

I see nothing said in the book, if I am not mistaken, about trimming, except to cut off the dead leaves, and perhaps cutting off the ends of the roots. Now, I don't know of any harm that these dead leaves do except to be in the way; but I do know of harm that some of the *living* leaves do, in all plants that ever I have bought. If a plant be taken up by means of one of Root's transplanting-tubes, and set out at once, all roots intact, and the soil adhering, not a leaf should be touched. But if the plants have come from a distance, the chances are that many of the little rootlets are so injured that they will never work again, and the number of leaves must be diminished to correspond with the number of working roots left. So I always felt safest to trim off all leaves except the center one, besides cutting square across the ends of the roots so as to take off perhaps a fourth of the longest ones. These long straggling roots don't get well planted, and a number of good working roots will start from the freshly cut ends.

PUDDLING.

Has "puddling" gone out of fashion? and is there something that I don't understand about it, that makes it better to lift the plants right out of water when set? When plants are taken out of water, you know what a tendency they have to cling together—just exactly what you don't want them to do. Stick them back in the water, and they spread out in a natural position; but the minute they are withdrawn they try to get into a single rope. Thus planted, there will be places where no soil will touch the roots, and holes left between. Now, what is "puddling"? Simply dipping the roots in very thin mud. Take a dish or pail of water, and stir into it all the soil it will bear, so that, when you stick into it the roots of a plant, and shake the plant up and down a little, the roots will spread out in a natural position. Upon lifting out the plant, each root will have a coating of soil, so they can not cling together as when taken out of the water, and will go into the ground in better position and condition. If the "puddle" be too thin, not enough soil will adhere to the roots; and if too thick, the roots will not readily go into it. Have too much soil in the bottom, and add water on top as often as needed. After puddling, the very fine little roots will stand out naturally, as you can not get them to do if you take them out of clear water. Leaving plants too long in clear water may injure them, and a puddled plant will not injure as quickly by drying.

MARKING.

In addition to the plans given for marking the ground, some might find it convenient to use a plan practiced by nurserymen. They

stretch a rope on the ground; then, pressing on it the blade of a hoe in front of them, they slide the hoe along as fast as they can walk, leaving the imprint of the rope in the soft ground. I have seen hoes with holes worn in the middle of the blade through much use of this kind.

You ought to have a big vote of thanks for getting out so practical a book. C. C. MILLER.

Marengo, Ill., Oct. 20.

Well, old friend, I do not know but we owe you a vote of thanks. I have several times felt a longing to try strawberries on just the plan you give, but our ground is too expensive, as you suggest. Cultivating both ways would certainly save a great amount of labor. We have practiced trimming—in fact, we always trim our plants before sending them off by mail; but after many experiments in sending out and receiving the plants, I am sure there are two extremes in the matter, and I would never trim them down to one leaf. We leave three leaves—counting the new one just pushing out. We received 100 plants in August, from New Jersey, trimmed, as you suggest, to one leaf; but while they all lived, the growth has been very much slower than with others where there were two or three leaves left. Matthew Crawford and Mr. Little both expressed themselves against trimming too closely, as they looked at the plants above mentioned. You give me a new idea in favor of puddling; and one reason why I have disliked putting the plants in a pail of water, is because the roots cling together in the way you mention. I shall try puddling again, with the additional light you give us in regard to it. My impression is, however, that the careful grower who really loves his plants will make them grow by almost any of the methods given. Pushing a hoe along the rope is another idea that will be valuable to me. We have always made a mark by walking on the rope; but this takes too much time where one foot is put tight up with the other as we walk.

PLANTING STRAWBERRIES IN THE FALL, IN FLORIDA.

Friend Root:—I consider your "crop" department one of the most interesting in GLEANINGS, and I always delight to read it. I have just read in the Sept. 15th number what you and S. P. Yoder have to say under the above head. Here in Florida, all of the hundreds of thousands of quarts of berries that are shipped out of the State every year are grown on plants set, for the most part, in September and October. These plants begin to bear the following January, and continue to bear until June. These plants are not set "by way of experiment," but by the *acre*; and, given the proper season and attention, they pay well.

Alva, Fla., Sept. 27.

H. G. BURNET.

Friend B., circumstances are so different between your locality and ours that there is no particular application except this: You have demonstrated that a plant that grows in the fall may bear a great crop of berries the following spring; but I presume that with you, as a

matter of course, strawberry-plants grow every month in the winter time, and have no rest at all. Well, now, do you plow them under after getting one crop, or do you keep the weeds out through all of the ensuing summer and get a second crop of berries from the same bed? And, by the way, what is to hinder you from getting a crop of berries in the fall, as they do in California? It seems to me that a timely application of water—that is, if you do not have it in abundance from the rains—may enable you to have strawberries for Thanksgiving and Christmas.

REDUCING THE NUMBER OF VEGETABLES, ETC.

Dear Friend:—Perhaps you are not aware of having a subscriber away down in old Tide Water, Va., who is depending so much upon you for valuable information in the horticultural line, and that I read GLEANINGS with great interest, and always await anxiously its arrival. Will you allow me the privilege of expressing my opinion in regard to your condensed seed catalogue? I think it is a capital idea, provided you cover the whole ground and include seeds for us large growers (the growers for the great Boston markets), as well as those who are growing for only a local market. Say, for instance, I am growing melons for the great market of New York. Were I to take your advice, and grow Landreth's Extra Early, why, it would be the means of my losing a good deal of money. I grew watermelons last year as a field crop, and realized about \$100 net profit per acre, and it was due to growing the right variety—Kolb's Gem.

In regard to your cantaloupes, while I have never grown Landreth's Extra Early, I can't agree as to the Emerald Gem and the Banana. My local market greatly prefers Miller's Cream; and while it is not so early, it is much the heaviest cropper; and my advice to my brother-truckers is, to grow the Hackensack or Acme, to ship.

In regard to lettuce for outdoor culture, the way we cultivate it down here, I think the Tennis Ball variety is second to none.

I agree with you about tomatoes. I have ripe tomatoes from the same vines that I began to gather from the 10th of June (Ignotum). The coming season I expect to grow 3 varieties—Ignotum, Burpee's Matchless, and Livingston's Beauty. I have never fairly tested the two latter. I think the only fault the Ignotum has is this: it won't stand dry weather, and will rot at the seed end.

Now, Mr. Root, I am a very good friend of yours, and I advocate your advice everywhere. I have profited more by reading after you than after everybody else together; and I feel as if I knew you, and would like much to meet you. If you ever come to old Virginia, and don't call to see me, I shall not like it at all.

I am a great friend to the son of toil; and if it is possible for me to speak in his behalf I will take pleasure in doing so. E. L. LIPSCOMB.

West Point, Va., Oct. 23.

Many thanks, my good friend, for the valuable suggestions you give us; but instead of helping to reduce the number, you rather give us excellent reasons why we should enlarge it. Well, this is just about as I expected; and as different localities and different markets require special varieties, perhaps it is impossible to keep the number down so small as I had planned, especially for a general seed catalogue.

MYSELF AND MY NEIGHBORS.

COPY OF A PAPER PREPARED FOR READING
AT THE NATIONAL CONVENTION IN
KEOKUK, IOWA.

Have faith in God.—MARK 11: 22.

Perhaps, dear friends, you think my text is a rather strange start-out for a paper on the honey-resources of the United States. May be it is; but I believe it is applicable to the subject in question, after all. For a little time back it has seemed to many of our bee-keeping friends as if our industry were going down hill. We have been in danger of losing faith in bee-keeping; and I fear that some of us have been tempted to lose faith in the great Ruler of all things. How can a man be a successful bee-keeper, without faith in an all-wise overruling power? How can he, in fact, be successful in any thing, in this whole wide world, without faith in God? In working, and devising means, and in planning for the future, what incentive is there to push ahead unless we have this faith? Perhaps some of you will agree with me in a general way; but I wish to exhort you to-day, not only to have reverence and respect for the all-wise Creator, but to have faith that he cares for us and loves us, and keeps watch over us, and hears prayer. During the past few weeks we have had an unusual amount of rainy weather—at least, such has been the case in Ohio and adjoining States. Men have planned, but God seems to have thwarted their plans by so much wetness. Shall we complain of him? Surely not. The words of our text bid us have faith in God. Shall we grumble at his dispensations? By no manner of means. There are certain things we can control, but we can not control the weather—at least, we have not done so yet; therefore we may safely say, just now at least, that the weather is God's part, and all we have to do is to attend to *our* part. Perhaps some of you say that I do not know what it is to have my bread and butter cut off by such unheard-of weather. I know something of it, dear friends. My crop of seed beans, including the bush limas, that are worth quite a lot of money, are still out in the wet. Many are rotted and spoiled hopelessly. My special crop of seed corn, that I value a good deal, has not been dry enough in a month to do any thing with, unless each ear be hung up in a dry place, as it hangs on a stalk. I must lose it, or cure it at a great expense. But I have not looked sour nor felt cross yet, although I sometimes have to say to myself, "Thy will, not mine, be done." It has been very perplexing for me to keep a large force of hands at work, for we do not send our men home when it storms, as many establishments do. Again and again have I asked God in the morning to give me wisdom in devising ways and means to keep my men at work, and at the same time have them work profitably. So far the answer has come, and I have often wondered how it was that things change around, and seem to dovetail one into another, in such a way as to call for just the man that I did not know what to do with next. Then how much happier one feels who has faith in God, and, as a natural sequence, faith in humanity! I fear, dear friends, that I should not have been away off here away from home, when so many things seemed to need me, if it were not for faith in God and faith in you. I believe we shall always be blessed and prospered in doing our duty, and duty seemed to call me here.

Now, about the honey resources of our own country. My faith is brighter to-day than it was a few years ago. I have prayed for our industry a good deal; and we have in our con-

COMMISSION MEN.

SELLING HONEY ON COMMISSION.

I think we should all try to build up our own home market, and we can do so by perseverance; but persons handling several hundred colonies of bees, and with no taste for peddling honey, often find more of it on their hands than they can dispose of in the home market. Then it is that we are thankful for honest and trusty commission merchants.

In the first place, I think people do not understand how to deal with commission men, as was the case when we began selling honey. The man who has honey or other farm produce for sale, more than he can well dispose of at home, should go to one or more of the grocery men in his nearest large town, and get the names and address of several commission men, and ask this grocer whether his dealings with such and such a man have been fair and honorable, and note it down; then select the man he thinks he can trust, and send to him for his circular giving daily prices of farm produce.

Possibly the producer has friends living in the city who could make inquiries for him, for a trusty commission merchant. That business is like all others—some very honorable men are engaged in it, and some very dishonorable ones as well. Then write to the man, telling him that you have honey to sell, and that, if he wishes to handle it for you, you will send him some. Send as soon as possible after his reply, *but not before*. Yet, one need not be in too big a rush, as we have found by much experience that the apiarist has plenty of time to sell his honey during fall and winter, and we always get just as good prices during the early winter months as in the fall months; yet I would sell as fast as I could conveniently get at it after the first of September, as honey sells most rapidly in October and November.

We always try to ship the first of the week, not later than the middle, that the honey may

arrive at its destination the same week. The apiarist should accompany the honey to the cars if possible, and help load it on, spreading out paper to set it on, and see that it is piled in with the ends of the section to the end of the car, the piles of cases not too high. The pile against the end of the car may be higher than the outside, and glass always inward, to avoid breakage.

Sometimes we can get a through car, so that it will not have to be changed from one car to another, which is often the cause of broken honey. Sometimes we can send it in a refrigerator car, which is a through car, and we could never see that the cold injured the honey. Send the bill of lading in the letter to the commission merchant, telling him how much per pound you ask for the honey. Sometimes we may name the price too high, and he can not sell; in that case he may hold yours and sell for others who have not named so high a price; but generally he will not hold it long, as he wishes his goods to move off, and he will either sell or notify you the price is too high, so you can write him again, lowering it. Of course, you keep yourself posted on the honey market. He has no right to sell at a lower price until you give directions. If the apiarist names no price, the commission man, if he is honest, and wishes your patronage, will do just as well by you as if you named your own price; but if he is not honest, it gives him a chance to cheat you if you leave the price with him, as I know they do sometimes sell at a better price than they report to the apiarist. If he is slow in writing you, write him again, and ask him how soon he will be sold out, and can handle more. Insist on having pay for as many pounds as are sent, fractions included, except, if the fractions result in less than 5 cents, it is usual to throw that in. Yet if the returns fall short 5 or 10 lbs. on several hundred, I should say nothing about it; but if it fell short much more I would instruct the commission man not to do so again, as it is not rular—*at least*, this is what our most

honest commission merchant wrote us when we asked him why it was his returns were so accurate, seldom falling short any in the least. The just weights, with fractions thereof, should be plainly marked on one end of the box of honey, and the commission merchant's address stenciled or plainly written on *top*, not on the side, so that the case need not be turned over to hunt the name.

Do not send very large shipments at first until you can trust your man, and then it is better to have less at a time, and quick returns, if one wishes the money to use; and the apiarist can care for the bulk of his honey better at home than the commission merchant can, only seeing to it that he has it as fast as he can sell it. There is one advantage in sending large shipments—it is not quite so apt to be changed from one car to another, and consequently it is not so apt to be broken up.

If an apiarist has honey enough to furnish a commission man all he can sell, so that he handles no other honey, that also is an advantage both to him and you. In that case it is well to ship to him just before he is out.

Always write him kindly and firmly, as if you expected him to do what is fair and honest. Unless you are personally acquainted, never take a note from him after the honey is sold. If he has used your money, and says he can not pay you, it is a criminal act; for it is criminal to sell on commission and use that money to carry on his business. And if, after all care and painstaking, you are about to lose your money (which you will not do once in a hundred times, and perhaps never), you can put your case into the hands of a trusty attorney, to collect for you. He will charge about 30 per cent, which seems high; but sometimes he will do it for less, which probably would be cheaper for you than to make a trip to the city, if far off, and you are pressed with business at home. More than likely it would never have to be taken to court. If the attorney simply states the case to him plainly, the man would see that the better way would be to get the money for you. In Chicago, 5 per cent is rutable for selling on commission.

In case of a loss when honey is shipped, get a statement from the freight agent where the honey was shipped or started, the number of cases sent, and in what condition, and put it in a letter, with a statement from your commission merchant of the amount of loss, and inclose with it the original expense bill, and send to the freight agent where the honey was consigned, for him to forward to the general freight agent of the railroad company. Do not send in an extravagant bill, but just what the lost honey would bring you, and you will always, in time, get your pay—at least, such has been our experience. At one time we sent honey to two commission men. It was put together in the same car. One was received all right, and the other was badly broken up—so much so that 1500 lbs. was unsalable. In that case it was probably broken by the drayman, in transit from the car to the commission house.

In very cold weather, several days before we ship honey we bring the cases of honey into a warm room, so that they may be thoroughly warmed through before starting; and, if packed compactly in a car, we think it not so apt to break down as to ship frosty combs. At any rate, we like to have it in the very best shape when it leaves our hands. We generally try to ship at the close of a cold spell, just as the weather begins to grow warmer, so that the honey may not be out in the coldest of the weather.

MRS. L. C. AXTELL.

Roseville, Ill., Oct. 22.

My good friend Mrs. A., you have given us

one of the best papers on this matter of selling honey on commission that we have ever got hold of. I was obliged to smile several times to see how thoroughly you have taken hold of every little point; and I am glad to know that you enjoy more charity, and do not rush to the conclusion that *all* commission men are corrupt because a few of them are.

A GOLDEN BEE-HIVE DISSECTED.

NOTES FROM THE SADDLE, AMONG THE MOUNTAINS OF KENTUCKY.

The writer, being engaged in the lumber and stave business among the mountains of Kentucky, meets with some novel sights and experiences. Perhaps a short sketch of some of these will not be without interest to the readers of GLEANINGS.

Menifee County is the smallest, and, I dare say, the poorest county, in the State. It consists chiefly of extremely large hills or small mountains. Its mineral resources are fairly good, but entirely undeveloped. Timber is at present about the only available product. Large bodies of poplar, and much linn, besides a vast amount of other bee pasturage, doubtless makes it a good locality for bee-keeping, and one bee-keeper informs me there is a "right smart of bees in Menifee;" but, so far as I can learn, they are almost entirely in antiquated box hives, or the still more primitive section of hollow log called a "gum." I talked recently with one man who has been keeping bees for many years, and who has yet to see a queen for the first time.

A very common method of taking honey is to destroy the bees with brimstone, or, with bolder ones, by breaking up the hives. Many beeb-trees are to be found in the woods; and it seems to me that, if the little fellows were as shrewd as intelligent they would all, long ere this, have deserted their masters and commenced business on their own account. They could fare no worse, with a fair chance of very much improving their condition by so doing. I thus far have met with but one man who has movable-frame hives. He has ten colonies, partly in box hives and partly in the notorious Golden hive, vended by Pickerl.

Riding along the road with "Langstroth on the Honey-Bee" strapped to the pommel of my saddle (to while away the time while feeding and resting my horse, you know) I came upon this little apiary, with hives scattered about on stumps and rocks in the yard. Such a sight, sandwiched in between high hills and forests, as it was, had a peculiar charm for me; and seeing the owner near by I cordially greeted him with "How do you do, sir?" and met with the characteristic Southern response, "How d'y?" After this, conversation ensued something as follows:

"How are your bees doing this season?"

"Oh, tolerable well."

"I see you have some Golden hives. How do you like them?"

"Oh! fine. They be the best tricks for keeping bees I've ever seed. One can take 'em all apart, and git right inside of 'em. They've got frames in 'em that come right out, and gives a chance to clean out the weevil that gets in 'em."

"I think I see they are marked patented."

"Yes, they're patented in 1877. Guess the patent 's about out on 'em. Man by the name of Pickerl 's bought the right for three States, Kentucky among 'em, and sold the right fur this county to Mr. —, over on Slate. He sells

the right to make 'em fur one's own use fur \$12. One man over here tried making some of 'em without buying the right, but they got on to it, and stopped him. Guess there'll be right smart of 'em made as soon as the patent 's out on 'em. Did you ever see any thing like 'em before?"

"No, sir, I never did; but I have heard of them, and am for that reason somewhat curious about them."

"Well, they be right smart ahead of the old boxes. I'll transfer all mine into 'em next year. I took forty pounds off 'n that 'n over thar, besides a good swarm I got of 'em. I count that purty good. Don't you?"

"Yes, that is good; but how do you take the honey off? and how do you get the bees off from it?"

"Oh! I forgot to say that they furnish a smoker and feeder with the right. And that smoker is just the greatest trick for handling bees that can be. I can just blow a little smoke into the hive, and it tames 'em so I can take out the frames, and they don't sting at all. There's two sets of frames. The ones below, we don't git much honey from. We just blow smoke into the top frames, and that drives 'em down so we can take out the top frames that has the honey. Then we can just cut it out of the frame and put it back in again. But may be you would like to see inside of the hive. I will go get the smoker and show you."

I dismount, and tie up my horse. Crossing the fence into the yard I meet him coming with the smoker, puffing the smoke from cotton rags furiously. He turns the nozzle into the entrance of the hive; and if there is any virtue in smoke, those helpless little fellows got the full benefit of it. After smoking them vigorously through the entrance he partially removes the cover by hammering and jerking it loose, and renews the smoking business from this point. He then ventures to remove the cover entirely, and I take a look into the hive. But my sympathies being fully aroused on behalf of the frightened and half-smothered little tenants, I thought they had received punishment enough on account of my curiosity; and after giving time for the smoke to escape I suggested that he cover the little fellows up, and I would show him how to open a hive without smoke.

I crossed over to another hive, and, carefully removing the cover, I began taking out the frames, making a general examination of the construction of the hive, while my friend stands back and gazes in open-eyed astonishment. I then told him that a smoker is a convenient thing to have at hand, and sometimes serves a very good purpose when bees are disposed to be cross. But generally I have no use for it, and I regard his method of using it a positive cruelty to the little fellows.

And now, friend Root, what a sight the inside of that hive would have presented to *your* critical eye! Why, if that man were a careful and systematic observer his short experience should enable him to give all you veterans pointers unlimited on the much-vexed questions of thick vs. thin, and wide vs. narrow top-bars, end-bars, and bottom-bars; close vs. wide spacing; irregular spacing, device for exact spacing, etc., for certainly he is trying all of them, and that, too, in one and the same hive. Every frame was a law unto itself, as to thickness and width of bars, size, and position. Spaces ranged from $1\frac{1}{4}$ to 2 inches from center to center, and this variation was sometimes existing between the same two frames. The hives should have had two more frames in each tier than he was instructed to use in them. How it puzzled the brains of the little architects to accommodate their building to their master's plan, was but too plainly evidenced in the wonderful variety

of combs they had built. Every style of comb was to be found there except straight.

The exact-spacing device was unique if not practical. It consisted of two lath nails driven in *one* side of each top-bar, projecting from half to three-quarters of an inch.

I closed the hive; and on being asked what I thought of it I told the gentleman that I had seen better, but that, with some very much needed improvements in frames, it would do, but that there was not a patentable idea in or about it, and that that part was a fraud. I then invited his attention to the book strapped to my saddle, and spent an hour in showing him through it, telling him of A. I. Root, the Home of the Honey-bees, the A B C book, GLEANINGS, etc., with the result that he concluded he *must* have the A B C; and if he found it as I stated, he thought he could sell lots of them. I gave him directions how to remit, and promised that I would have a catalogue and copy of GLEANINGS sent to him.

Wheelerburg, O., Aug. 21. J. M. BROWN.

It may be well to remind our readers that this Golden bee-hive is one that has a forged testimonial from Prof. Cook. Treat every one who tries to sell or talk Golden bee-hive, as you would treat a forger or counterfeiter.

RAMBLE NO. 32.

CONUNDRUMS; MAYDOLE HAMMERS, ETC.

When we left home it was our intention to return via Syracuse, Borodino, etc.; but "the best-laid plans of men and mice gang aft aglee." The force of circumstances found us away south of that line in Chemung Co. Here we found near and dear friends, and not many bee-keepers. Our relatives and even bee-keepers, wherever we went, were very hospitable, and did their best to entertain. Sometimes we were inclined to think they were overdoing the matter. With some of our talkative friends it was a steady run of talk until midnight. We couldn't get a chance to read the papers or write a letter; and even at meals, questions were answered with our mouth full of hot potato. Sometimes the man of the house and his wife would take turns. If he stepped out, she would step in; and when both went out, the hired girl was sent in.

Now, there is quite a difference in the quality of hired girls. Some are decidedly handsome and entertaining; they read the papers, read the poets, and play the organ, and sweetly sing. With such a queen of the kitchen we didn't mind much how long the heads of the family did stay out. The smartest hired girl we met on our journey was not only musical, but full of riddles, and let one drive at us the first thing. "Why do a dog's lungs give out first?"

After many futile efforts we gave it up.

"Because," says she, "it is the seat of his pants."

Now, we had been sitting around in chairs rough and smooth, and we surmised that our pants were getting rather thin in some parts, and we surmised that this girl was insinuating; but before we could change the subject she let drive another:

"If the Devil loses his tail, where will he go to get another?"

"Don't know, unless he would come to Millport and hunt up a hired girl."

"Oh, no!" said she; "this is a no-license town. He would go where they re-tail spirits."

The hired girl's question may not entertain your readers, however, and we will turn our

attention to the leading bee-keeper of this place, Mr. Jim Stewart. He was greatly in favor of the Italian bee, and we immediately commenced discussing their merits. He had about twenty colonies, and said every one of them was fine Italians. Upon examination, the first swarm we pronounced genuine old-fashioned blacks.

THE RAMBLER TRYING TO GUESS A RIDDLE.

"Oh, no!" said he; "*you* are mistaken. Italians are very dark until the third year; then they get their yellow bands."

"Then you expect this colony of black bees to turn yellow in three years?"

"Yes, that has been my experience with them."

"Did you ever send for an Italian queen and introduce to your colonies?"

"No, sir. I leave such fancy processes to my neighbor, Nat Goodwin, who lives about two miles down the valley."

Our friend's three-year theory was easily explained. The wonder is, that his neighbor's Italians did not change his blacks to Italians at a more rapid rate. Nothing we could say would shake his three-year theory.

In Elmira we made a short stop. The only bee-keeper we called upon here was Mr. Rutan, a carpenter by trade, owning about forty colonies. These were quite near the sidewalk, with no intervening fence, and we were informed that pedestrians were hardly ever disturbed or stung, and Mr. R. seemed to be enjoying his right to keep bees in a city. His hive was patented, and has the high-sounding title of "King of the West." A neat honey-house stood convenient to the apiary, and was well filled with honey and fixtures.

Our next stop of any importance was in Norwich, Chenango Co., where a hammer factory attracted our attention. The Rambler's cousin has much to do with this factory, which made it the more attractive; and as every bee-keeper is a wielder of some kind of hammer, perhaps a few facts about this establishment will interest.

Several years ago, David Maydole, an humble blacksmith, invented the adze-eye hammer, and made one for himself. A carpenter saw it and wanted one, and he was supplied; then several men who make nail-driving a business wanted hammers. Thus orders continued;

more men were employed, a new shop erected, machinery invented, and the Maydole hammer-works arose to their present proportions, occupying a large brick building, and employing over one hundred men. Over sixty different styles of hammers are made, and tons of steel are manufactured into one of the best hammers known; for a hammer with the Maydole mark upon it has a solid reputation. The hammer was never patented; and during our trip, everybody was harping on the one string, "dull times." But in answer to our question as to dullness in the non-patented-hammer trade, I was told that the business had never seen dull times. Their orders were away ahead of their manufacturing capacity, and they were preparing to enlarge their works. Mr. Maydole now rests in the cemetery, but his works live after him.

THE RAMBLER.

Friend R., there is a bright moral to your story of the Maydole hammer. The originator was an energetic, go-ahead son of toil, and he reaped his reward. Opportunities are constantly opening up in almost every avenue of work, to go and do likewise. "Seek, and ye shall find; knock, and it shall be opened unto you."

CLOSED-END FRAMES.

A FURTHER DISCUSSION OF THE SUBJECT.

I had begun to write about a few results of moving bees with the wide and narrow end-bars, and the use of reversing wires, when today I received Oct. 25th GLEANINGS. In it I see that you have nearly if not quite decided on the wide end-bar and the follower. I have in my possession a letter from you concerning a hive I wrote to you about, and almost fac-simile in parts; and in it you say that it is too complicated. Now, I wish to give you two points that, within the past five years, I have had to deal with enough to make me cautious. First, that the follower must not come nearer than $\frac{3}{8}$ of an inch to the bottom of the hive, or there will be some expensive mashing some time of a queen. Second, if you allow a half-inch space between that follower and the hive side, one of these days there will be some comb built in there during a sudden flow of honey, when it is least expected.

On page 745 you have pictured a cross-section of nearly the hive that I have used and seen used—the staples and all. Now, I must say this for hives that are to be moved; and, in fact, for any other purpose. Those staples are not worth a fourth what your reversing wires are. I have carted bees around from place to place for over 15 years. Until I obtained some of those reversing wires, I have not been without more or less frames and combs being broken from the top-bar. A sudden jar will start them somewhere, and those jars come when least expected; but with the reversing wires, all the strain comes on the center of the end-bar; and if the combs have been properly handled they have been reversed enough to make them solid in the frame.

Another feature of the wire is, that the spring in the end of it is of value in moving because of the give that there is to it. I have just been moving quite a number of hives to have them in a safe place for winter; and although all the narrow hanging frames were wedged as tight as they could be, some of the all-wood top-bars were started, as they have been in years before. Many of those with tin corners needed to have the pliers used on them to straighten them; but those with reversing

wires were in no way injured, and some of all sorts were on the wagon at the same time.

Now to go back to the hive you are thinking of: $12\frac{1}{8}$ inside measure; wide, make it $12\frac{1}{4}$ or $12\frac{3}{4}$, and use two followers $\frac{3}{8}$ or less thick, with the lag strips on both sides at the ends of the follower, and a $\frac{1}{4}$ -inch wedge. Those followers will and do spring. I have used the follower with the narrow frames for the past 12 years, alongside of hives without it, and the follower is worth more, from the ease that it makes in handling, than it costs, every season; and with two followers in the hive with wide end-bars, the two followers are all ready to contract the hive to the combs in the center, be it 3, 4, or 5, for their winter and spring packing.

There are a great many who will say, "Too many loose pieces;" but actual use makes me think differently; and trying the Hoffman-Langstroth frame since 1878, along with the others, and the wide end-bar since 1881, I must say I will have only the wide end-bars for me on the new frames in the future; and I want them to be hanging frames too. I have used, since 1886, 1200 hanging frames with the reversing wires on; 300 of them were new wide-end-bar reversing frames, and they will continually replace all others. In 1884 and '85 I helped to make and use 45 hives that used the L. frame with $1\frac{3}{4}$ end-bars, top and bottom bars $17\frac{3}{4}$ long, held in place by tin rabbits, top and bottom fastened by hooks. This made a perfect reversible hive and frame, separately or together; but, no more of them for me of the L. depth, and all the hive to reverse. They are too slow to handle, and are not as satisfactory as are the hanging frames. Neither do I want the standing frame, although there are plenty of nuclei to be seen in several places made by setting up two or three wide-end-bar frames with a board on each side and a string tied around. It is fun sometimes to save a lot of cells in that way. It is simply two side panels and two or three combs in closed-end frames, and two wire springs from telephone wire bent thus — one snapped on to each end to hold the side panels in place. These side panels are just followers $9\frac{1}{2}$ wide, $17\frac{3}{4}$ long, with $\frac{1}{8}$ -inch strips nailed on the ends on both sides. The back ends of the frames rest on the board if you like. They all pile away nicely in the fall and winter when not in use.

I also see that you have taken note of the thick top-bars for the prevention of the brace-combs, and that the scant bee-space is another preventive of the brace-combs and climbers between the crate and brood frames. I have been using both thick and thin top-bars; but when the bee-space above the brood-combs was $\frac{1}{4}$ inch, the brace-combs were missing. Unless the space between the brood-combs and the space between the two sections corresponded, then there would invariably be a little ladder built; but with the inch-wide top-bar there is far less chance; and an inch-wide top-bar makes more difference than the thickness of it does. I have used top and bottom bars $\frac{3}{8}$ thick up to $1\frac{1}{2}$ thick, and I have watched those used by others; but the spacing above the combs makes more difference than all other causes put together. I became convinced of the difference of the space connected with brace-combs in the summer of 1884; and also that the scant space, when the two stories were used for extracting, this shallow space would be filled nearly or quite full of propolis. Where I have cared for bees for the past 12 years there have been a few localities where cedars, hemlock, tamarac, pines, and juniper abound, and in those localities, after the summer harvest is by, the bees take delight in gluing every joint

tight that they can get the gum into. So there are two evils to try to dodge—the comb-braces on the wide space, and the propolis on the narrow space. Which is it to be? and I am not the only one who keeps bees and is between the two fires?

H. L. JEFFREY.

New Milford, Ct., Oct., 1890.

By consulting our sectional drawings on page 745, we find that we left $\frac{3}{8}$ inch below the bottom of the follower, so we are all right on that score. About those staples: We have been experimenting some on the driving of the same in closed-end frames; but on account of their twisting in driving we have decided that a good substantial wire nail, with a finishing head, such as is used by Mr. Tunnicliff, is better. I agree with you, that a closed-end frame for the Dovetailed hive should be made to *hang* rather than to *stand*; but I shall have to disagree with you somewhat in regard to reversing-wires. These wires will all stick out so as to require a space between the ends of the frames and the end of the hive. For closed-end frames it is very desirable, and, I might almost say, necessary, that the bees be excluded from the side next to the hive, otherwise they will propolize the outside as well as the inside places of contact between the uprights. E. R.

SPACING FRAMES IN CALIFORNIA.

A COMPARATIVE TEST BETWEEN $1\frac{3}{4}$ AND $1\frac{1}{2}$ INCH SPACING; A CONCLUSIVE RESULT FOR $1\frac{3}{4}$.

I will give you some of my experience with spacers, spacing, and moving bees. About ten years ago, when I owned about 40 colonies of bees, I thought something to hold the frames the right distance apart would be a good thing, so I bought a lot of blind-staples and drove two in each end-bar on opposite sides of the frame, in all the frames in my apiary. I extracted from the brood-chamber then, and soon found that the staples would not do in frames that had to be extracted; so I pulled them all out and have not tried spacers since. If I were answering the question on page 675 now, however, I would say, "Yes, if you have learned the business so you do not need to look over all the brood-combs every week to know that a colony is doing well." A frame like the modified Hoffman would be less bother through the season than it would be to fasten all the frames twice a year for hauling. This applies to brood-chambers only. Super frames should never have any projections, and should never be over $\frac{1}{8}$ wide.

I use a device in hauling bees that holds the frames, on the same principle as the Hoffman frame—that is, by making a solid bearing for three inches down the end-bar. I think it was invented by R. Touchton, and is made as follows: One piece is $\frac{1}{4}$ x $\frac{3}{4}$, by as long as your hive is wide inside; nine pieces $\frac{1}{2}$ x $\frac{1}{4}$ x 3 inches; nail the nine pieces to the first piece in the shape of a garden-rake, $1\frac{1}{2}$ inches from center to center, and shove these teeth down between the end-bars. Before I came to California I always spaced my combs $1\frac{1}{2}$ inches, and, like a good many others who are spacing their combs that distance now, I thought it was right and best. When I came here I found most beekeepers spacing their combs $1\frac{3}{4}$ inches. I was prejudiced against that distance, and changed

200 colonies to $1\frac{1}{2}$, and ran them that way for two years, side by side with others spaced $1\frac{1}{2}$. The hives spaced $1\frac{1}{2}$ reared more brood, stored much less honey above the brood in the brood-chamber, and consequently stored more in the supers, built less brace-comb between the top-bars, and reared less drones. I changed all my hives back to $1\frac{1}{2}$ centers, and it would be a hard matter to induce me to even try $1\frac{1}{2}$ -inch spacing again. I say that $1\frac{1}{2}$ is right for the brood-chamber, and from $1\frac{1}{2}$ to $1\frac{3}{4}$ is right for the extracting super, with a queen-excluder between super and brood-chamber.

My honey-crop this year is 27,000 lbs., all white and thick, and put up in new 5-gallon cans, two in a case.

There is a war going on in California, between new honey cans and cases, and second-hand oil cans and cases. The new cases cost 90 cents each, and the oil-cases cost 40 cents each. Dealers keep advising bee-keepers not to use oil-cans, and yet they will not pay the difference in cost for new cases. If it were not for the fact that oil-cases are bound to hurt the market for California honey, we would all put our honey in them, for we can not afford to pay from one to two hundred dollars a year to have our honey look nice, and not get any more for it.

Fillmore, Cal., Sept. 26. J. F. MCINTYRE.

UNITING BEES, ETC.

FRIEND DOOLITTLE GIVES US MINUTE DIRECTIONS JUST HOW TO DO IT.

I have just been uniting up some weak colonies of bees, or, rather, large nuclei, as they would be more appropriately termed; and I liked the way I did it so well that I thought the readers of GLEANINGS might wish to know how it was done. In the first place, the queens in a part of the colonies were taken away to fill late orders; but if I did not wish to use the queens not needed in the united colonies, I killed the poorer ones, as I considered them; for, so far as I have practiced this plan, I find that queenless bees are less inclined to quarrel, and are more disposed to stay where put, than are those having queens. Having the queens disposed of, from the colonies which are to be united, wait three days to a week (three days in any event, so the colonies may realize their queenlessness) for some cool cloudy day when it is from five to ten degrees colder than is required for the bees to fly, when you will find the bees all clustered compactly, something the way they are in winter. When taking the queens away, take all the combs from the hives but three (the three which contain the most honey), and spread these combs about three-fourths of an inch apart, setting them out about two inches from the side of the hive, so that the bees may be all clustered on these combs instead of hanging to the sides or any part of the hive. The hive which is to receive these bees and combs is to be also prepared beforehand, by taking away all the combs but three or four, those being left being the ones having the most honey in them, said combs being placed close to one side of the hive.

When the right day arrives, light your smoker and put on your veil, for in following the plan described you may not be able to use the hands to get a stinging bee off the face as you otherwise would; for, during a part of the operation, both hands will be so employed that you can not use them at any thing else. Now go to the hive having the queen, and uncover it, giving the bees a little smoke to keep them quiet, and leaving the hive open so that you can set the other frames right in without any hindrance.

Next go to one of those that you took the queen from, blowing plenty of smoke in at the entrance while uncovering the hive. Blow a few puffs of smoke around the combs and over them, when the smoker is to be set down, the two front fingers placed between the two first frames near their ends, the large fingers between the second and last frames, while the third and little fingers are placed beyond the third frame. Now close up with the thumbs and all of the fingers, thus lifting the frames and cluster of bees all out of the hive at once, when they are to be carried to the open hive where they are to stay, and sit down in it all together, close up to the frames of bees that are in this hive. Go back and get the smoker, and blow smoke enough on the bees to keep them down, when you can arrange the frames, division-boards, and hive, as you like, without very many, if any, bees flying. Should a few bees stick to the hive that you took the frames out of, bring the hive to the one having the united colony in it, and brush them out on top of the frames, as they will be pretty well chilled by this time. In doing this you will have to smoke those in the united colony pretty well, or many will fly at you, for these partly chilled bees will throw their poison out on their stings so that the scent of it will anger the bees that are in the united hive. If you fixed all as it should be when taking the queens away and preparing for uniting, and smoked the bees as I have told you, there will be only now and then one that will require this last operation, as all will be snugly clustered on the combs. Close the hive as soon as you have things fixed to suit you, when you are to remove every thing from the stand of the colony that was united with the other, so that, when the bees come to fly on the first warm day, they will find that all that looks like their old home is gone. Some bees will fly or hover over the old spot where home was, but, not finding it, will return to the united colony. In this way I never have had any quarreling of bees, nor any queens killed; and it is so simple and easy that I like it much the best of any plan of uniting bees late in the fall.

DEAD BEES AT THE ENTRANCE.

A correspondent writes thus: "We have had a week or more of very cold weather for the time of year; but yesterday was so pleasant that the bees came out from the hives. This morning I found great numbers of dead bees at the entrances. Was it so cold that they died before going back in, or what?"

No, the trouble was not that it was too cold when the bees were flying, for bees rarely fly at this time of the year when it is too cold for them to get back. Really there was no trouble, unless it was that your bees were not properly protected from the cold during the previous cold spell. I would not be afraid of guessing wrong if I said that your bees are in single-walled hives; for in chaff hives many bees do not die during the first cold snap, as they do in single-walled hives; for I take it for granted that the dead bees you found out at the entrance were the bees which had died in the hive during the cold spell you speak of, and that the live bees had drawn them out at the entrance on this pleasant day which you speak of. Now, while a chaff hive keeps many bees from dying early in winter, yet I have an idea that these bees that do thus die on the approach of winter are nearly or quite worn out by old age, hence they do not keep pace with the receding cluster, and are thus carried off early in the season, yet are really of no great account, although making quite a showing at the entrance, to one not knowing the cause of their being there.

Borodino, N. Y., Oct. 29. G. M. DOOLITTLE.

THE INTERNATIONAL BEE-ASSOCIATION.

A FEW NOTES OF THE PROCEEDINGS, BY
ERNEST.

On account of the very poor season, and the failure to get reduced rates, the most of us predicted, in our own minds at least, that the meeting at Keokuk would not be as largely attended as the former ones. But we consoled ourselves that what it would be lacking in numbers would be made up in enthusiasm. Well, we were very much disappointed as to the attendance, and agreeably so. If I am correct, there was the largest enrollment of members ever made in its history, and I heard on all sides that it was the best meeting ever held in the history of the association. While the one at Brantford had, I believe, a larger daily attendance, yet the paid membership was greater at Keokuk. It was surprising how the bee-keepers of the Mississippi Valley and adjacent territory turned out. Well, the fact was, that not all of them had had a poor honey crop, and, of course, they came. Others had a poor season as usual, but they could not afford to miss the opportunity. There were several from Colorado; one or two from Arizona; two from Canada; some from Kansas, Michigan, Ohio, Indiana, besides a good representation from the border States—Illinois, Missouri, and the home State, Iowa. The failure of the honey crop, and the absence of reduced railroad rates, was more than counterbalanced by the persistent and efficient services of the secretary, Mr. C. P. Dadant.

The two representatives of GLEANINGS had figured to be on hand at the opening of the first session. The train being behind time, we did not arrive until near the close of the session. The question-box had been opened, and your humble servant whipped out his note-book and pencil, craned his neck, and proceeded to jot down a few things that seemed to him to deserve special mention. Let me say right here, that this report is far from being complete. It contains only a few of the good things said and done.

At the latter end of the morning session, the first question I heard was, "What is the relative consumption of stores as between sugar syrup and good sealed honey?" It has generally been thought that there is but very little difference in favor of either; but by some careful experiments, President Taylor had found that there is a decided difference in favor of the sugar syrup. On honey the bees are very apt to become uneasy and excited; and careful weighing showed that the consumption of honey was much more than the consumption of the sugar syrup. I think he said the bees would consume about a half more of honey than of sugar. Some were inclined to take exceptions, on the ground that the experiments were not carefully conducted. I remember that W. F. Clarke asked the president *why* honey excites the bees more, and then went on to give his reasons for his disbelief. The president interrupted him by saying, "Let me ask *you* a question. What effect does honey have on you?" "I can not eat a bit of it," said Mr. Clarke; "honey gives me colicky pains."

The convention roared with laughter, and Mr. Clarke resumed his seat. I do not give this to show that Mr. Clarke was beaten in argument, but simply as a sample of the pleasant bantering back and forth.

CANE OR BEET SUGAR—IS THERE ANY DIFFERENCE?

Mrs. Harrison asked whether there was any difference between cane and beet sugar. Opinions were various. The president argued that there was a difference. A. I. Root, Mr. Dadant,

and others, claimed that there was none. Mr. Secor cited the *O. Judd Farmer*, to the effect that cane and beet sugar are precisely one and the same thing. I did not say so at the time, but somewhere I read (I can not say just where I saw it), that the amount of cane sugar produced is very small indeed compared with that produced from the beet. If this be true, the probabilities are that the sugar on our tables, and that which we feed our bees, is *beet* sugar. Mrs. Harrison stated that the *British Bee Journal* was authority for saying that there is a difference between the two sugars, and that of the two the beet is inferior. Oh how we missed Prof. Cook at this point in the convention! We all knew he could help us out. Well, it is not too late yet.

EXTRACTING HONEY TO FEED SUGAR.

A further question was put as to whether it would pay to extract the honey, and feed sugar. It was argued that it would not, because the stores usually left for winter are from fall sources; and if the bees do consume more, nothing would be gained, from a dollar-and-cents point of view, by extracting and feeding. R. McKnight thought any one who would advocate anything to the contrary was a fit subject for the penitentiary. Dr. Mason quickly got up, "Then I am a fit subject," and sat down, amid roars of laughter—another sample of bantering. Along in the afternoon we listened to the

PRESIDENT'S ADDRESS.

It was an able document. He called attention to the lessons of the poor season. There are a great many outgoes and expenses, and the bee-keeper becomes discouraged. Total failures are expensive; but, he argued, we are not paying too high a price for the benefits of that which will follow. In the convention there should be a free discussion—no personalities. Instead of saying, "In my opinion," state what you know to be a fact, leaving out the matter of opinion, because that is understood. Free discussion leads to the best understanding. He thought the floating character of our association a bad feature. There is no fixed membership. Even the officers may not be members next year. Why not have the association incorporated under the law, and members contribute, whether they go or not? He advised that we consider the matter of the World's Fair, and that immediate action be taken.

The address was not discussed immediately, but a committee was appointed to consider some of its salient points. For further particulars, see *Myself and My Neighbors*, elsewhere.

BEE-PASTURAGE OF THE UNITED STATES.

A paper was then read by A. I. Root, on the bee-pasturage of the United States. He alluded to several of the promising sources of nectar, and gave, incidentally, a talk he had had with Mr. Draper and Mr. Hambaugh, on the train, in regard to Spanish needle. Both of these gentlemen stated in convention that they live not a great way from the Mississippi Valley, and had secured a large crop of honey from Spanish needle. In fact, this seemed to be a never-failing source. Many of their customers prefer it to clover. It is very thick, of good color, and of delicate flavor. Mr. Hambaugh had secured in five days, from one hive, 73 lbs. I was surprised to learn that the Mississippi Valley, along in these regions, was covered in waste places with Spanish needle; for it seems there are a good many bee-keepers who get a nice paying crop from it. It is a significant fact, that in one locality a honey-plant may be a valuable source of nectar, while in others it may be worthless: so with Spanish needle. In the matter of honey sources we should take into

consideration locality. This point was emphasized by Mr. W. F. Clarke. Mrs. Harrison, in crossing the Mississippi, had discovered hundreds of acres of Spanish needle, and the bees were just rolling in the honey.

BUTTON-BALL.

Mr. S. A. Shuck had no Spanish-needle, but button-ball honey. It comes in bloom with him about the 5th of July. It is of good color, and yields a good quantity. Under favorable circumstances he had secured 7 lbs. per day per colony for eight days.

THE CHAPMAN HONEY-PLANT.

Γ A. I. Root related that Prof. Cook had tried it on an extensive scale, and that he (Cook) had concluded that it was not a profitable bee-forage for cultivation. Mr. Axtell had tried it, and it yielded honey, but he did not think it paid.

QUESTION-BOX.

On the evening of the first day the question-box was opened again. The question, "Can poultry-keeping and bee-keeping be profitably combined?" Dr. Miller was called upon to answer. He said he did not know very much about it, but he would read a letter from a friend, on the subject. All the reporters, anticipating something solid and serious, grabbed their pencils and began jotting lively. Very seriously and innocently he read Sockerie's experience with a sitting hen. Very soon the reporters and the rest began to "catch on" to the hoax, when they perceived that it was a side-splitting impersonation rather than a serious detail of facts. Those of you who have had the pleasure of hearing the doctor deliver some of his comic pieces, can get something of an idea of the fun we had. Stripping the little story of its German brogue and its funny hits, a certain Dutchman, not very big up and down, but big all around, proceeded to set an old hen in the barn-loft. He could not reach up to the hen's nest with a hatful of eggs in his arm, so he stood upon a barrel. Perhaps you know the rest. The head of the barrel gave way, and his fat sides telescoped into the barrel, but the nails sticking out prevented his wife from pulling him out. I do not know, but perhaps we had better give the whole chicken story at a future date, so the doctor will please present it to our readers.

Another question was, how to get rid of black ants in the apiary. Pour coal oil, coal tar, or diluted carbolic acid on their nests.

My note-book does not record very many things said and done at this stage of the convention. I presume I got tired, or, what is more probable, there was so much fun that the pencil could not properly record it.

THE "DON'T KNOWS" OF BEE-KEEPING.

The next morning we listened to a spicy and well-written essay—in fact, a model for bee-conventions, from Dr. C. C. Miller, entitled, "What I Don't Know about Bee-keeping." He did not know how far to space combs; whether there is greater or less loss from wintering indoors or outdoors; whether poor seasons are valuable to bee-keepers or not; how to prevent brace-combs; whether fixed frames are practical or not, and how to prevent swarming; and, "I don't know"—but I had better stop." And he closed with a hearty applause. His "don't knows" set us to thinking. When a practical chord is touched, how a convention will respond! The doctor touched a number of practical chords, and the one singled out in particular was very suggestive.

HOW FAR TO SPACE COMBS.

It was argued that Nature spaces them about $1\frac{1}{2}$ inches. But the opinion seemed to prevail,

that, because Nature does so, it is no reason why bee-keepers who wish to properly control brood-rearing should do so. One important fact was brought out, that several who had formerly used $1\frac{1}{2}$ -inch spacing had discarded it for $1\frac{3}{4}$, but nary a one was there who had tested both ways of spacing, and had settled on $1\frac{1}{2}$ -inch. Testimony was not wanting, to the effect that more brood could be produced on $1\frac{3}{4}$ spacing. Wm. Lyon, of Burlington, Ia., said that, when bees wish to go into sections, space the combs closer. By so doing, bees are less liable to swarm, and would the sooner put the honey above. He even went so far as to say that thus he almost entirely does away with swarming. Dr. Mason and A. N. Draper had used successfully spacing as close as $1\frac{1}{4}$ inches from center to center; but the convention seemed to feel that that was going a little bit to the other extreme. Mr. L. C. Axtell argued for $1\frac{3}{4}$, but he did not have very good success with closer spacing. He has a mellow soil, and occasionally his hives would tip one side and the other. He does not wire the combs, and sometimes combs would bulge toward each other by the tipping of the hive, making less than $1\frac{3}{4}$ spacing in places. He noticed that brood-rearing was curtailed in said places. He used fixed frames, closed-end Quinby, on $1\frac{3}{4}$ spacing, and liked it. B. Taylor had used $1\frac{1}{2}$ -inch spacing, and had changed to $1\frac{3}{4}$. The latter he had used for 26 years, and saw no reason for changing.

There was a good deal of bantering in regard to Dr. Miller's expression, "I don't know." The doctor, having been a bee-keeper for many years, has learned that there are a good many other things that he does not know. While we were arguing about what we *did* and *didn't* know, our old friend J. W. Bittenbender, of Knoxville, Ia., arose, and repeated one of Josh Billings' sayings: "What is the use of knowing so much, when so much you know ain't so?" and sat down without comment. Verily, brevity is the soul of wit, sometimes.

[To be continued.]

THE DOVETAILED HIVE.

WHAT HENRY ALLEY HAS TO SAY OF IT.

During the last thirty years, which comprise my experience in bee-keeping, I have given a good deal of study to the bee-hive question. Some twenty years ago I obtained a patent on a hive. I believe that that hive was the first double-wall hive used in this country—certainly the first patented double-wall hive. Since that time I have constructed about a dozen different styles of hive; but at no time did I lose sight of several important features that, it seems to me, should always be found in all good bee-hives; namely, the Langstroth standard frame, with a wide and thick top-bar. What I call a bee-space was another important feature always retained in all styles of hives used in the Bay State Apiary. Not over $\frac{1}{4}$ inch, and slightly less, is what I consider a proper bee-space between the tops of the brood-frames, or whatever is used over them, whether it is a section-case, honey-board, or what not. When more space is given, brace-combs are found, as well as propolis, etc.

Early in October I visited a large display of bee-hives at the Rhode Island State Fair. I think there were not far from thirty different styles of hives on exhibition. There was a hive from about every dealer in the country who had ever made or invented a hive. I looked the entire lot over, and saw but one hive that seemed to combine many good features, and this hive

lacked but one thing to complete it. This hive was Root's Dovetailed. The thing lacking was an outside case for winter and spring protection. With that addition I should consider the Dovetailed hive as good as the Bay State, as then it would combine nearly all the good features of the hive we use in our apiary. Bear in mind, we use, in the Bay State hive, both the closed-end and standard Langstroth frame.

I have had a good opinion of the Dovetailed hive; and now that the out, or winter case, is to be adopted, it seems to me it must prove to be one of the best hives in use.

I don't want to say one word against the other hives I saw at the R. I. State Fair; but it is a wonder to me that such hives are used by any one. The lumber-bill for 100 such hives, it seems to me, must be immense.

PACKING BEES FOR WINTER.

I may be radical on this point, yet it does seem to me that, with any good double-wall hive, no packing is necessary in winter.

Now, Bro. Root, as you are a strong advocate of packing, why not try an experiment? Why not place 50 hives in a row, pack each alternate colony, and let the others winter with the air-space open?

I know from past experience, that the unpacked hive will not only winter better, but will do the best the following season, and come out stronger, cleaner, and better in every way in the spring. Here in New England, where we never have more than three days of settled weather at one time, we need no packing, save a mat or cushion over the bees, to absorb moisture and prevent too much draft up through the colony and combs.

HENRY ALLEY.

Wenham, Mass., Oct., 1890.

Thanks for your testimony for the Dovetailed hive. When it was originally constructed, we did not have in mind any pet theories, but simply endeavored to combine in one hive the demands of the largest and best and most practical bee-keeping, having in mind due reference to economy; and that these requirements have been met is evidenced by the "carload" demand for it. You are right. A wide and thick top-bar with scant $\frac{1}{4}$ -inch bee-space, is among the necessities of a good hive.

I am greatly pleased to get so good an authority as yourself for an outside protecting shell for winter; and I am not sure but that your remark in regard to *packing* versus *air space* is true. I have, for a year or so, hoped that it might be so; and facts are beginning to come in with the proof. If we can leave out packing (I say *if*) and yet obtain as good results, it will be a blessing to bee-keepers. All single-walled hives can be cheaply converted into double-walled winter hives; and then, too, during summer these winter cases will be worth all their cost for shade when placed over supers while on the hive. Mr. Elwood uses just about such a case over his supers, and yet whole apiaries of his were exposed to the direct rays of the sun. They are better than a shade-board, because it shades the *sides* of the supers as well as the top. Here is an article from J. A. Roe, in a similar strain:

THAT OUTSIDE PROTECTING SHELL.

I was very much interested in W. A. King's article on page 697, and in Ernest's comments,

especially where he speaks of winter cases, as I was then getting out a descriptive circular of what I call the "hive-protector." This is made high enough to take in a single-walled hive, with two cases of sections or an extracting super, and large enough to set four chaff dummies around the brood-nest for winter; or, what I consider better and more convenient, is the band suggested by Ernest for his winter case. The hives are to be left in the protector the year round, as they afford protection from the hot sun and cool nights in the summer time. But, as A. I. R. says, when these cases are made good and substantial, and all complete, it brings the cost to about the same as a good chaff hive (including the cost of inside hive), so it is not so much a matter of economy as to whether this arrangement is more desirable than a chaff hive. As the inside hive can be readily lifted out, this will be much easier than lifting heavy chaff hives where new swarms are hived on the old stand, or any operation requiring hives to be moved; and with the chaff band made from thin lumber, and permanently packed, it is but the work of a moment to set this over the brood-nest, put on a top cushion, and you have as good a chaff hive as there is. Where bees are wintered in the cellar it is a small job to give them spring protection with this arrangement. A great many neglect to protect their bees, and I think those who do find it an unpleasant task, to say nothing about the unsightly appearance of the apiary, and the litter when unpacking in the spring, or the injury that may result from leaky covers.

J. A. ROE.

Union City, Ind.

We take the following description of the cuts from his circular:

J. A. ROE'S OUTER COVERING FOR SINGLE-WALLED HIVES.

I desire to say a few things about bee-hives, and hope you will give me a patient hearing. "Which is the best general purpose hive, i. e., the chaff or single-walled hive," always has been and perhaps always will be an unsettled question. That both have their good and bad points, I think most will admit. Let us see: The single-walled hive does not cost nearly so much as the chaff hive; it is much easier handled (and this is quite an item where new swarms are hived on the old stand), and is a much cooler hive in summer. I know a great many will not agree with me in this last statement, claiming that a chaff hive is cooler in summer. But how can it be, when we know that any thing that will confine the heat in the winter will do the same in the summer? and good authorities say the heat of the brood-nest during the hot season is nearly 100 degrees. If this be true, it is also a fact, that, the thinner the hive up till the time the outside temperature reaches that of the inside temperature, the better can the heat escape; and the thicker the hive, the more will it be confined. I have noticed that bees always lie out much more in chaff hives; and I fail to see the difference between wearing an overcoat to keep the heat out and keeping bees in chaff hives to keep them cool. * * * The hive-protector makes a chaff hive out of any single-walled hive for winter, and gives plenty of shade and ventilation for summer. It is made of such dimensions that a single-walled hive with two cases of sections can be set inside of it, and four chaff dummies, three inches thick, set around the hive (these dummies are made of thin lumber, and should be kept in the dry when not in use). The hives are not to be fastened in the protector, and it does not interfere in the least with the ordinary

handling of single-walled hives, such as hiving new swarms on the old stand.

The protectors are to be leveled up and located permanently; and when hives are to be moved, lift the inside hive out. Shade for the hives during the heat of summer, I think, is quite an advantage; but shade-boards are unsightly, and frequently blow off. The hive-protector not only affords perfect protection from the hot sun, but also from cool nights, when the bees are liable to be driven from the cases. The protector is made in two styles, the one with shutters, and the other using thin lumber for siding. I do not advise the shutters, on account of the extra expense, as just as good ventilation can be secured by raising the lid an inch in the hottest weather, when the heat of the inside hive will cause a current of air to pass up around the hive.

THE HONEY CROP OF SOUTHERN CALIFORNIA.

BEES AND FRUIT; VALUABLE TESTIMONY FROM
A BEE-KEEPER AND FRUIT-GROWER THAT
BEES DO NOT TOUCH SOUND FRUIT;
YELLOW-JACKETS THE GUILTY
CULPRITS.

I caught particular fits for predicting in GLEANINGS that Southern California would produce but half a crop of honey unless we had later rains. Now, although every one was watching and waiting, hoping and praying for them, they never came. Then they got mad at me—especially the honey-dealers—and pitched into me. Mad? Yes. What right had I to call the attention of the world and his brother to the possible failure of the honey crop? Would it not be bad enough when the world *had* to know it? Why alarm the trade, and send up the price of honey only to collapse again? Besides that, the failure would never come. Look at the face of nature! Was any thing ever more promising? I looked. Gentlemen, I admit the wide earth is covered with a carpet of matchless green. The alfalaria, the buttercup, and the daisy, with a thousand other flowers to the deponent unknown, are fighting for standing-room all around me. The king of the honey-plants—the black sage—all along over the mountain-sides, throws out its sheen of white purple snow. We look around us, and the eye is “dazzled and drunk with beauty.” The air is loaded down to the hub with the perfume of the flowers. We feel all over that it is simply ecstasy to live. Any man can jump up and yell—yell with pure and unalloyed delight; yell that he has such a country—all his own; yell that he has a home to go to, and doesn’t have to board out. But in two or three weeks there will be a change—all these flowers will become thirsty. They will look up all the day long to the pitiless sky, and yearn for a little water. The stalks that now bear up their load of bloom so proudly will creak in the wind, and moan for a little water. The leaves will reach out to you with a pallid and appealing look, and seem to ask you with such beseeching tenderness to give them but one drop of water. Were you ever starving to death—starving for water? Were ever your lips parched and black—your teeth covered with a thick coat of gum for want of water? No? Then you know nothing about it. I imagine it is about the same way with the flowers. We see their pallid faces—see their fading forms—see their daily change till they droop and die. But we know not whether they have a consciousness of the change. Now, gentlemen, have any of you got a little patent pump about your clothes, that will water all this broad expanse of Southern California? No? Then look out for the honey crop. Those who are close to large alfalfa fields *may* get a good crop—as they mostly do. But

all who depend upon wild feed—as nearly all do—will suffer indeed. And we did suffer.

BEES AND GRAPES.

I have seen Prof. McLane’s experiments with bees and grapes called in question by some of the bee-papers. But I think I could convince the greatest skeptic of their truth and reliability. We are now picking our grapes and making our raisins. Now, friend Root, walk up into the vineyard with me. You see we are cleaning the grapes at tables. You see and hear thousands of bees on the tables, on the long line of cleaned grapes, on almost every vine around you, and flying around your head. Take this bunch of grapes. You see half a dozen bees busy on it. They are sucking the juice from the half-decayed grapes, and those that have been picked by birds. You know already that a bee will suck the juice from rotten or broken fruit. But here is another bunch—the grapes about as large as your best eastern plums. Every grape is as pure, perfect, and unblemished as if it just came from the hands of the Creator. Hold that up for five, ten, fifteen minutes, and not a single bee will alight upon it. Oh, yes! they will fly round it and sniff at it, but they won’t alight on it. Why? Simply because there is nothing for them to get, and they won’t try to pierce a grape. Now you are satisfied that no bee is going to alight on that bunch. But pull one single grape off it, and see the change! There is a large, luscious grape at the top—near your hand. But, hold! Have your mouth wide open and ready to shut the door when the grape goes in, or you may have a small family of bees in there too. You must do this or take a walk once or twice around that grape before eating it. The moment the grape leaves the stem the bees will dash at both of them for the fresh juice. These facts, which I have tested again and again, prove that bees do no injury to grapes or fruit. But yellow-jackets can and do pierce the grape. They will, in cool cloudy weather, cut the cheese-cloth into shreds and go in and destroy grapes or raisins.

RAISINS, AND HOW THEY ARE PREPARED IN CALIFORNIA.

This is the way we clean the grapes for raisins. Theoretically, you are not allowed to touch the bunch at all—except by the stem. When you touch the grapes it rubs off the beautiful white bloom that covers the amber tinge in the White Muscat of Alexandria. Catch your bunch by the stem. Pick off every premature grape; every one that has not come to perfection; every one that is cracked or broken; every one that shows any indication of decay; every one that has been picked by birds; in fact, *any* grape that has any fault at all. Now cut the stem as close to the bunch as possible, and lay it carefully on the tray beside you. This is the whole art of cleaning the grape. These trays of cleaned grapes are carried to one side and placed end to end. The trays are just a yard long and two feet wide. I cover mine with cheese-cloth. The grapes will cure in 12 or 15 days in first-rate raisin weather, under the cheese-cloth. It takes 20 or 25 to cure them, with the best of weather, under the old system—that is, bareheaded. The cloth protects the grapes from dust, dirt, and insects. Woe to the yellow-jacket or bee that gets under that cloth on a warm day. For these reasons the cloth makes a better and cleaner raisin.

In four or five days the beautiful green grapes that you placed on those trays will have undergone a change. You take off the cloth for a hundred—two hundred yards. There, spread out before you, is apparently an immense long line of soft, mushy, rotten grapes. A stranger

to raisin-making would pronounce them lost. If there were in your armor a crack or a crevice he would thrust in one of his arrows of consolation. But, wait! Don't make them into vinegar or sell them to the wine-maker yet. Wait three days—it may be four. Now see the change. The top of the fruit has shrunk downward. The beautiful blue tinge of the perfect raisin has appeared; and, better than all, there is the magnificent bloom of the green grape that disappeared on the second day—come back again to beautify and glorify its old home! Now they are ready to turn. An empty tray is turned upside down on top of the first full one. Both are drawn a couple of feet from the row (to give room to work) and whirled over. Thus the full tray becomes the empty one, and serves to turn the next. When this side that you have just turned up gets the blue tinge, and the bloom is apparent, the raisins are ready for the "sweat-box." This is a box 10 or 14 inches deep, and a little larger than the tray, so that a tray will go down into them. You take your tray, put the open side (one side has no rim) down into the opposite side of the box. As your raisins slide off you draw the tray toward your side of the box, and the fruit will slip in, just as it is laid on the tray. The sweat-box is a misnomer. The raisins do not sweat—they merely equalize. Some are too dry—some not dry enough. They commence to trade off as soon as they get together. In four or five days they are all alike—ready for the packer.

You gave a very good idea of packing raisins, in your Riverside article, when you returned from California. But the fellow who put the bad raisins in the bottom and the best on top was a rascal—there is no getting over that. I do not here wish to represent myself as an extensive producer or packer. I have but a small vineyard. But he who has a small vineyard must understand the business as well and as perfectly as he who has his 5000 acres. If he doesn't he will come to grief.

I see you made a slight mistake in regard to raisins at Riverside. "London Layers" is only a name for the best quality of raisins. It does not indicate that they were either built, brought up, or educated in London. The early packers gave their best raisins this name to indicate that they were fit for the London market. Some pack under the name of Crown, Double Crown, and Treble Crown. But I think that Americans should discard all these imperial and foreign names. New York can eat as good raisins as London or any city in the world—yes, and pay for them too! Why not change the "London Layers" to "New York Layers"? There are really but three grades of raisins. The second grade is simply "Layers." The third is "Loose Muscatels," for cooking.

A great calamity has befallen the raisin interest this year. It commenced raining on the 26th of Sept., and continued, at intervals, for three days. At this time about all the raisins in Southern California were spread out in trays, many of them just fresh picked—some half dry. When it quit raining it was evidently against its will. It wanted to rain—threatened us for eight days more. It was cloudy and murky, and now and then it would take a dash at us at night. The green grapes rotted, and will have to be picked over, at a great loss. The half-dried raisins will be greatly damaged. There will be an actual loss of 100,000 boxes in the southern part of the State.

THE FIRST SECTION BOX.

In a pleasant conversation with J. S. Harbison he informed me that in Oct., 1858, at the State Fair at Sacramento, he exhibited the first section box that ever was made for honey.

Was it the first section box? Is there any section box that has an earlier record? He also informed me that he used the solar wax-extractor in 1860. But he does not know who was the original inventor. Others used it before him. He seems to think it invented itself. His words were, that it came naturally into the head of any bee-keeper. They are called solar honey-extractors here, from the fact that all honey was extracted by them for many years. They are used still for that purpose by many farmers. I have seen them 20 feet long, three feet deep, and four feet across the top. They are made like a trough, and lined with tin. A wire screen fits in, half way down.

Olivenhain, Cal.

J. P. ISRAEL.

Thank you, friend I. I would by all means mark the raisins so that nobody could be misled; and I do not see why *California* layers is not as good a name as any.—I have no knowledge of any sections previous to 1858, and that dates back before I was a bee-keeper, and before we had any journal on bee culture in the United States.

GETTING THE BEES TO EMPTY OLD BROOD-COMBS.

FOWLS' PLAN.

Dr. Miller says he has reduced the time to two or three days. Well, I get the job done in 24 hours, if the weather is warm enough so the bees will fly freely; but if it is colder his plan is no doubt the best where the hives have a loose bottom. If the doctor tries to have old black brood-combs emptied his way when the weather is warm, I imagine he will have a "hot time" taking the combs away, for the bees will hang to the old combs a great deal worse than they will to the unfinished sections; and of all disagreeable work, shaking hungry bees off dry combs is the worst.

As before mentioned, his plan will not do for those who have hives with a permanent bottom, like mine, and I will therefore give my plan, which is simply a slight

IMPROVEMENT ON DR. MILLER'S PLAN OF HAVING UNFINISHED SECTIONS CLEANED OUT.

I take my old combs that I want emptied, and, after uncapping the sealed honey, I put them in empty hives with tight bottoms, and set them down close to the entrance of the colonies I wish to feed, just at dusk. I put in a less number than would fill the hive, so they are spaced further apart; and if I want to feed more combs I put on an upper story. If it is a cool night I put the hive as close as I can to the entrance; if warm, three or four inches off, after getting the bees started on it, the object being to avoid getting the young bees out of their hive.

Nearly all of the honey will be cleaned out in the night, and early next morning I carry the hives of combs two or three rods to one side from the apiary, and close the entrance small ($\frac{1}{2}$ or $\frac{3}{4}$ inch will do); but if combs are new and tender, or contain any candied honey, they should be closed to a one-bee capacity.

Now, the bees that are already on the combs have the advantage through the day, and will get about all the honey there is left; and if they are managed so as to have no young bees on the combs they will all go home at night, leaving the combs free from bees, when they can be taken care of. By this plan I can get a hundred or more combs cleaned out every day until the job is all done with, and the light colonies

supplied with their winter stores, and all without lighting a smoker or opening a hive. I do not work with the bees during this comb-cleaning time; that is, not in the home apiary, where the work is done, and so I have no trouble with robbers. CHALON FOWLS (*per Violet*).

The following is a private note sent along with the above; but as it contains a "gleam of news" we take the liberty of giving it also. Violet's penmanship is as plain as a type-writer, and our printers wish other papas would call upon their little girls in a similar way.

Mr. Root:—I inclose an article. I wrote it to-day in such a hurry that I could hardly read it, so I got my little girl to copy it. The honey crop is small here. I took only about 1000 lbs., but I am happy just the same, for a "stranger" has arrived at our house; and although he doesn't pay his board, and talks kind o' queer, we have concluded to adopt him; and—well, you know how it is yourself.

Oberlin, O., Oct. 24.

CHALON FOWLS.

ERNEST'S NOTES OF TRAVEL AMONG THE BEE-KEEPERS OF YORK STATE.

BICYCLING OVER THE MOUNTAINS TO ALBANY.

The next morning Mrs. Root took the stage for Hunter, at which point she was to take the train to New York, to meet her sister. In the meantime I donned my bicycle suit, oiled up, and stood in readiness to take a fifty-mile run to Albany. It had rained furiously on Sunday, and the roads were not in the best possible condition. With some misgivings, Mrs. Root bade me good-by, and off I started. I made pretty slow progress. Instead of going down to the Hudson, and following the river up, I decided to take a shorter run across the country. I had gone hardly five miles before I almost had a notion to turn back, as the roads were so muddy that, in several places, instead of the bicycle carrying *me*, rather than get it all mud I picked it up and carried *it*. I traveled along in this way until I came to a pedestrian. Some of the time he was away ahead of me and some of the time I was up even with him, and it was somewhat humiliating to be plodding along at that rate, knowing that fifty miles or so were ahead of me. I thought that, when I got to the top of the mountain I would sit down and coast all the way. I arrived at the top, and behold there was another magnificent view; but as I have exhausted all my vocabulary of adjectives, I can not stop now to tell you about it. I commenced coasting, and all was very fine for a while; but the road grew rapidly stony and rough, and it seemed to get steeper and steeper. The brakes would hardly hold me, and some places were so rough that I had to dismount and hold the machine back. I never had the attraction of gravitation torment me so much as on that ride from Mount Pisgah. It was a continual pullback all the time. On the way a stone caught under the guard, and I thought sure then that the machine was utterly smashed. I stopped and cleaned the mud out, reached the stone, scraped out the guard, and away I went.

There was nothing particularly attractive on this road to Albany, except, perchance, the mud. Like the same article in Ohio, it would stick to the wheels, get under the mud-guards, and whenever I dismounted it would cling to my feet. The roads seemed to grow worse and worse. So rough and stony was the land that

agriculture seemed to be developed but little beyond its primitive form. I saw log houses and ox teams. Here and there were box hives; and one place I remember in particular had in its front yard from forty to fifty skeps. I thought of turning in and asking the owner of those bees a few questions. Possibly he might give me an idea or two; but every thing was so dilapidated, house and all, that I decided to go on. I was traveling at a pretty fair rate, when just back of me I heard a low growl, and the rapid patter of feet. Looking back I saw it was one of those

LARGE FEROCIOUS BULLDOGS.

He had come from the yard where I saw the box hives, and he was after me full tilt. Unfortunately the road was rough, otherwise I could have left him in the race. I put on all speed, however; but, despite all I could do, the dog was coming nearer and nearer. I felt every moment that he would grab my stocking legs, and the cold chills crept up my back. I never had a nightmare that was more real. I was thoroughly frightened, and I longed for a weapon of some kind. Something that I could not do ordinarily I did this time. While the wheel was in full motion I whirled about in the saddle, and, with heels sticking out behind, kicked out back. I ran into an obstruction, and the next thing was bicycle, rider, and dog, pretty badly mixed up. I was on top of the bicycle, and the dog on me, and I thought my days were ended. Although on my back, I grabbed for his throat, and kicked lustily with my feet. The dog was evidently as much or more surprised than I, for, the next thing I knew, he was running for the box hives, with his tail between his legs, yelping as if the evil one were after him. I picked myself out of the mud, and, with a stick, scraped that article off. I mounted the saddle again, and at the next house I came to I stopped for a drink of water. A good-natured farmer came out, and, observing my dilapidated condition, asked me whence I came and whither I was going. I told him, and then related the squabble I had had with the dog, and desired him to convey the intelligence to the owner of the box hives, that, the next time I came along that way, I would surely kill his dog. As I never expect to travel the same route again, the dog will probably not die by my hands.

Perhaps I might say here, that one of the things that annoy bicyclists along the country is good-for-nothing dogs whose chief business is to annoy passers-by, and who seem to have a particular dislike to bicyclists. This is not the first fracas that I have had with dogs. In one other instance, one of a ferocious type actually grabbed me by the calf of my leg, and hung on. I was at my wits' ends to know "what to do, and how to be happy while doing it." A thought struck me on the instant. Turning to the dog I said sternly, "Jack, go back into the house, sir! Go back, sir!" It was quite evident that the animal had heard this before. Letting go he looked at me as much as to say, "Well, may be I have made a mistake," and back to the house he went. Usually, when the roads are fair I run away from them. If I have a fair start, it is a pretty good dog that can even catch up with me.

But, to return. I wearily wended my way over the bad roads, until I reached the suburbs of the old city of Albany. A man passed me, and said, "They are waiting for you in the city."

"Who?" said I. "Bee-keepers?"

"Bee-keepers!" said he in surprise, and we both passed on, neither knowing what the other meant. I had supposed that he meant that

there were two or three bee-keepers in Albany who expected me that day, and that, when I came, we would go into camp at Lake George. He, in turn, meant that a company of wheelmen were on their way to Syracuse. There was one important member, as I afterward learned, whom they were waiting for; and supposing me to be that individual, he thought he would hurry me up. I had gone very nearly fifty miles over roads that were hardly passable for even a lumber-wagon, and I had taken nearly all day to do it; and, to make matters still worse, the streets of Albany were the worst paved of any I ever came across. I dismounted, and pushed my wheel on the sidewalk. A burly policeman, with his club uplifted, very respectfully advised me to get into the road, with its muddy and uneven places. I complied. I soon reached the hotel, and took lodging.

AT THE CAMP OF BEE-KEEPERS ON LAKE GEORGE.

The next morning, about 9 o'clock found me in the city of Troy, the place where they make collars and cuffs by the carload. After visiting with friends and relatives, I left my bicycle in the city, and took the train for Lake George, which I reached that afternoon. My friend F. A. Lockhart, of Pattens Mills, near Lake George, was on hand at the Depot. A couple of lady bee-keepers, Miss Douglas and Miss Wolcott, came on the same train. I went to the hotel, and the two ladies went with Mr. Lockhart to the camp. The next morning Mr. Lockhart came after me, and very soon I had the pleasure of meeting Rambler. Yes, if I had not been told so I should have known that good-natured, rather tall individual driving a black horse. Then there was Mr. Lockhart's father, one of those pleasant, hearty Scotchmen that it is a pleasure to see. There was also John H. Larrabee and his brother; Mr. and Mrs. G. H. Knickerbocker, Mr. Higley, and several others whose names I have forgotten.

Mr. Lockhart, Sr., owned a cottage along the shore of the lake; and as the attendance at the camp was not large, the tents brought by Rambler and "genial John" were not used. We accordingly all of us took up our quarters in the cottage. There was just enough to make a good-sized family, representatives from Vermont, New York, and Ohio. A couple of rowboats were at our disposal, so that we could take rides upon the lake; and, in addition to that, a small steamer, rebuilt by a son of Mr. Lockhart, of queen-rearing fame, came around both days to our camp. In addition to this there was fishing-tackle, and every thing else in the sporting line, that could make such a camp delightful, to say nothing of the beautiful scenery round about. The boys had been out fishing that day, but succeeded in catching only four or five small minnows; and during the time I was there, no large fish were caught.

We talked bees, we talked bee-keepers, and I should not be surprised if we indulged in a little gossip, not only at each other's expense, but at the expense of some who were not present. We visited as only bee-keepers can, until late in the evening. The ladies of the party retired at a *reasonable* hour, but the rest of us had not finished talking yet. As in almost every crowd like this there was one comical genius (Brodie Higley by name) that, no matter what he said or did, we had to laugh. Rambler has spoken of him as the bee-keeper who attempted to winter his bees on wagon-wheels; see GLEANINGS, page 635, 1888. It was growing late, and our friend Mr. Higley could keep awake no longer, and finally, in an upright posture, he went off into a doze, while we talked and

laughed. As he leaned back in his chair, his appearance was exceedingly comical; and, no matter how hard we laughed, the sounder he slept. A thought struck me, and I proceeded to put it into execution. I brought all the lamps we could spare, so as to get a good illumination on the face of our friend, and I was just then quietly poising my camera, that I might have a permanent record of his face—his mouth wide open, and he himself enjoying all the bliss that sleep can give, when, lo! he suddenly roused up and glared at the camera. He did not see any thing to laugh at, although the whole crowd of us fairly yelled. Pretty soon he quietly retired to a corner of the room, and was soon fast asleep. Not long after, the whole of us retired, it being my happy lot to sleep with the Rambler. The next morning I got up feeling any thing but refreshed; my sides were sore from laughter of the previous evening.

A RIDE ON A BEE-KEEPER'S STEAM LAUNCH.

That day our crowd was invited by the Andrews to take a ride upon the little steamer—an invitation which we gladly accepted. I took along my Kodak, and took photographs of several of the mountains. To give you just a fair sample of the beautiful scenery, I give you one of the instantaneous views herewith.

A VIEW ON LAKE GEORGE.

I stood up in the steamer, and the view taken shows a part of Mr. Andrews' hat, and, I think, a corner of Mr. Larrabee's face. You can see that the shot was instantaneous, as the ripples and the waves are apparently motionless.

We visited most of the principal points at that end of the lake; stopped at Mr. Andrews' cottage, romped about a while, and finally returned. It was suggested by one of the party, before leaving the steamer, that we have a photograph of it taken. Both Rambler and I tried our hands at it, but neither succeeded in getting very good views. Then after the party left the steamer they stationed themselves on the shore, and we both took a shot. There was a sort of spring-board on the end of the dock. In order to take in the whole crowd I had retreated clear to the end of this board, and the water beneath was perhaps 15 feet deep, and as clear as crystal, as is the character of the whole lake. I had stepped just one step back too far and came very near taking a plunge bath—camera and all, and after a good deal of wiggling I regained an upright posture. The crowd on the shore were in the height of their

hilarity at my expense, when at that instant I secured a photograph. The place being a little shady and dark, the picture is not clear enough to reproduce; but I never saw broader grins on the faces of a party than are shown in this little miniature photograph. That afternoon we went out in a row-boat, and we were shown a place where a certain man-of-war was sunk during the French and Indian War. The water is as clear as crystal; and when the lake is still enough, I am told that this old relic of our forefathers can be seen at a depth of 40 feet.

That afternoon I was obliged to leave, although some good fishing was promised me if I would stay. The rest I will leave for the Rambler to relate, which he will do in a forthcoming article soon.

To be continued.

PURE ITALIANS VS. HYBRIDS.

DR. C. C. MILLER VOTES IN FAVOR OF ITALIANS.

Like yourself, friend Root, I was a little surprised at the answers on page 752 to the question whether pure Italians or hybrids would do a better season's work. And now, upon making a careful canvass of the replies, I am again surprised to find my first impressions were so far from correct. The impression left on my mind, after reading the replies, was that the general consensus of opinion was that hybrids are better for work than pure stock. Instead of such being the case, I find that, of the sixteen replies, aside from my own, seven prefer Italians, four prefer hybrids, one thinks there is no difference, and four are non-committal. Having kept bees solely for the sake of having the honey to sell, I have never cared for color, whether yellow, black, or green, only so they gave me the most honey. The reports of others settled me in the belief that hybrids are just as good workers as pure Italians; but every year or two I got an imported queen for the sake of infusing fresh blood. Most of the queens I raised were daughters of these imported queens, but for the last two or three years I paid less attention to the matter, leaving the bees to a great extent to raise queens to suit themselves. As I had for so many years been bringing in imported queens my bees were all either pure or hybrids, and the few bees surrounding me would be pretty well Italianized. Not rearing queens for sale, and believing that hybrids would give me just as good results as pure Italians, why should I trouble myself any more than to throw in a little fresh blood now and then? The yellow blood being in the ascendancy, I could reasonably expect it to remain so, even if I never got another imported queen; and by bringing in a fresh imported queen every year or two, the black blood ought soon to work itself all out. But I was surprised to find the number of very dark hybrids on the increase—a good many of that sort that kind of hang along without getting ahead much, and allow the worms to take possession—and in 1889 I actually found two or three colonies that no one would suspect of having any yellow blood in them—pure black. I also found that, instead of wearing a veil on my hat, to be pulled down only occasionally, I had gradually come to wear my veil down all the time.

In the A B C, friend Root speaks of the vindictiveness of hybrids. In my comments thereon I say, "My hybrids do not and never did deserve the reputation you give them. Perhaps one in two hundred may, and then a queen loses her head." But the "one in two hundred" became quite a number in one hundred,

and there were times when I dreaded to go near them.

One day as I sat working at a hive, having had a little more than the usual quota of stings, I looked up from my work, and, with suppressed groans (and, I presume, with unsuppressed lugubriousness of countenance), said to my assistant, "If I knew that this thing were to continue straight along in this way, I think I should want to give up the business." Instead of giving me the hearty sympathy I had a right to expect, she merely looked at me and laughed very heartily. To this day I don't know just what she laughed at. There was nothing funny about it.

In that same summer of 1889 I had a good illustration of how much trouble some people will take to avoid trouble when a pet theory is involved. I had a visitor whom I will not name, further than to say he came from Medina, and was somewhat barefooted on the top of his head. While among the bees I urged him to put on a veil. Not he; it was too much trouble. Do you know that, all the time that man was among the bees, he spent his whole time blowing a smoker about his head, puffing first on one side then on the other. If he had been obliged to work at a hive he would have taken a good many stings, or else would have taken to his heels.

However well he stuck to his theory, I had to give up mine. I concluded hybrids were not as good for me as pure Italians. However good a first cross may be, if such are encouraged they are sure to be followed by second, third, and sixteenth crosses, among them such crosses as *are* cross and very poor workers. So this last summer, wherever a colony showed the least taint of black blood either in color or disposition, the queen of such colony was remorselessly destroyed and replaced with one of pure origin. This brought death into some of my best colonies. The queens were killed, not because of what they were, so much as because of what might come after them. As a general rule I am kept too busy to keep close track of the qualities of each colony; but in one case I did give close observation. I had an imported queen whose workers, in appearance, pleased me less than any I had ever had. This led me to watch narrowly their conduct for some days, to see if they were any more industrious than others in the same apiary. There was no mistaking it; there was not only a difference, but a *marked* difference. Especially in the morning was this noticeable, for no other colony in the apiary sent out so strong a force, although some were more populous.

Hereafter, if a colony of hybrids be found among my bees it will be by no design of mine.

Marengo, Ill., Oct. 22.

C. C. MILLER.

Friend M., if you had had decent bees, instead of the kind you did have, I should not have needed a bee-veil or smoker either, at the rate your bees were getting honey during my visit. Very likely that is your opinion, as well as mine, so we can drop it right there.

A WINTER REPOSITORY.

PLANKS FOR CEILING BOARDS.

I have recently built a bee-cellar which I should like to describe, and have an expression of opinion from yourself and others as to its wintering qualities.

My apiary is situated in a valley and near a small swamp. The soil is sand and gravel, and there is just enough rise so I could dig down

three feet for the cellar, and still have a three-inch tile drain, sunk below the cellar floor, which comes out at the edge of the swamp sixty feet away. The cellar is $8\frac{1}{2}$ feet high from floor to ceiling; 15 feet long, and 8 feet wide. I used cull ties and slabs to support the earth, which is banked against the sides and on the top. The earth is 3 feet thick where the bank begins, and slopes up to the eaves, where it is about 6 inches thick. The roof is flat, and the earth is piled up on it to a peak. The whole is covered with a thick layer of marsh grass, which keeps the earth perfectly dry. For ventilation I have the tile drain and an 8-inch ventilator in the roof. For an entrance there is a hatchway made in the same manner as the main cellar, with outside, middle, and inner doors, by which, if necessary, one can enter without admitting any light or cold air. I shall put in only 70 colonies this winter, but I think 150 colonies could be wintered in it. I built it because I have no cellar near the apiary. I would rather construct such a cellar than move the bees even half a mile to reach one. Such a cellar can be constructed for \$25.00 if one is near a sawmill where cull timber and slabs can be purchased cheaply; and by keeping the roof dry I think it will hold for a number of years.

HARRY LATHROP.

Browntown, Wis., Oct. 17, 1890.

Planks or slabs will do well enough for two or three years for ceiling boards, but in time they will rot from the moisture of the bees, and the whole thing will cave in—perhaps at a time when you can least afford it. Mr. Doolittle's cellar had planks for ceiling boards under the dirt similar to yours, but they rotted and caved in this spring. They might answer if lined with tarred paper.

THE SOLAR WAX-EXTRACTOR.

HOW TO MAKE AND HOW TO USE ONE.

One of the most convenient things I have in my apiary is the solar wax-extractor; and as it is so handy to have around, I thought that, with your permission, Mr. Editor, I would describe it at this time, so that, during the dreary winter days which are coming, any of the readers of GLEANINGS who desire to have something which they would appreciate in years to come could spend a day or two of time in making something that would brighten other days, even if it did not the days they were working at it. In order to make it plain I will give the size and number of pieces contained in the extractor, by numbers, and then tell you how to put them together.

Number.	Pieces.	Length in inches.	Width in inches.	Thick.
1	2	30	10	$\frac{1}{2}$
2	2	14	10	$\frac{1}{2}$
3	3	15 $\frac{1}{2}$	10	$\frac{1}{2}$
4	2	30	$\frac{3}{4}$	$\frac{1}{2}$
5	2	17 $\frac{1}{2}$	$\frac{3}{4}$	$\frac{1}{2}$
6	2	32	4	$\frac{1}{2}$
7	2	16	4	$\frac{1}{2}$
8	2	34	$\frac{3}{4}$	$\frac{1}{2}$
9	2	18	$\frac{3}{4}$	$\frac{1}{2}$
10	1	34	19 $\frac{1}{2}$	$\frac{1}{2}$
11	2 straps	10	1	
12	1 sheet American	30	18	
13	2 stove-pipe iron	30 $\frac{1}{2}$	16 $\frac{1}{2}$	

Having these pieces cut to the dimensions above given, take No. 1, which is for the sides of the body of the extractor, and nail to the ends of No. 2. Next nail No. 3 on to one side for a bottom. If No. 3 are made from matched lumber, and all joints put together with white lead, no loss of heat will occur from its escaping through the cracks or joints where the extract-

or is put together. Nail No. 4 to the outside of the extractor, at the sides, $\frac{1}{2}$ inch from the top, for the glass frame to rest on, and then nail No. 5 to the ends of No. 4 and the extractor. Now nail No. 6 to the ends of No. 7, for the glass-frame, putting the glass, No. 13, into the grooves cut for them, before nailing. These grooves should be $\frac{3}{8}$ deep, the upper one being $\frac{3}{8}$ from the top, and the next $\frac{3}{8}$ below the first. Unless you can nail this frame or sash very carefully, so as not to break the glass, perhaps it would be better put together with screws. The frame is put together with white lead, the same as the body was; but there is no lead put in the grooves, as we could not get the glass out, should it ever be broken, if we did; and I find that air passes very slowly where it has to go around anything in the way it does this glass. Next nail No. 11 to the center of this glass frame at each end, nailing them in such a way that they will form loops or handles, for the frame is to be handled by these, slid off and on, etc. Now nail No. 8 to the ends of No. 9, nailing No. 10 to the side of the frame made by nailing Nos. 8 and 9 together for a cover to go over the glass frame when the extractor is not in use. This cover will keep the glass from getting broken by hailstorms, or from any other causes, and will also keep the storms from swelling our extractor by getting the inside wet. If you can not very well have No. 10 in one piece, narrower stuff with the cracks battened will answer all purposes. Also, if you can not get glass of the size named, several, 16 $\frac{1}{2}$ inches long, will do by making the joints so they will not come over

DOOLITTLE'S WAX-EXTRACTOR.

each other so as to let the heat out too rapidly. Now take No. 12 and spring the middle down till the edges come even with the top of the body of the extractor, and snugly against the back of this body, when it is to be nailed along each side to the side of the extractor. This will give you a hollowing trough on which to put the material which is to be rendered into wax, and the black surface of the iron will so absorb the rays of the sun that it will become very hot in a short time after the cover is taken from over the glass. If a piece of $\frac{1}{2}$ -inch stuff is fitted on the under side of number 12, 5 inches back from the front or open end, so as to keep the hot air from going under the iron, it will help some about keeping the wax melted in the dish into which it runs while extracting. This keeping the wax melted in the dish helps much about getting it caked in nice form.

HOW TO USE THE EXTRACTOR.

Select some place, as near the center of the apiary as possible, where the sun will shine from 9 A. M. to 3 P. M., the year round, and there

place a piece of 2x4 stuff, as long as your extractor is wide. Fix this piece so it will rest secure on the ground, and hew it each way from the center, till the ends are 2 inches square. In the center put a pin of $\frac{3}{4}$ -inch iron, while a $\frac{5}{8}$ -inch hole should be bored in the bottom of the front end, or No. 2, to receive this pin. Next, provide several pieces of 4x4 stuff to put under the back end of the extractor, so that you can lower or raise the back end, according to the season of the year, or, in other words, according as the sun is high, as in June, or low, in November. From the middle of May to the middle of August the extractor will do all you want of it, if faced directly south and left so all the while; but earlier or later it will need turning on the front pivot at least three times during the day. At nine, face it southeast; at noon, south; at two, southwest. To thus face it, was why our front "sleeper" was fixed with the pin as I have given. Every scrap of wax that is taken from the hives while at work in the apiary is put into the extractor as we pass by it, and all that accumulates in the shop is placed in a pan kept handy by for this purpose, and the pan is taken and emptied into the extractor as often as is necessary. When there is a sufficient accumulation in the extractor, the cover is taken off from over the glass some sunshiny day at 9 A. M., and the wax allowed to "extract." When the whole mass is melted that is on the iron, slide the sash to the front, and, with a wooden paddle about 3 inches wide, draw all the refuse up on one of the inclined sides to near the top, pressing on the paddle considerably, so as to break any of the cocoons that may not have broken, so that all of the wax may work out. In this way the wax will all run out as clean as it can be gotten out in any other way, and I used to think that I could get out 100 per cent of it in a kettle of water. After all the wax is out, and while the whole is still hot, draw out the refuse with a scraper made of wood for the purpose, when the extractor is left all clean for another batch of wax scraps. If left till cold, this refuse will stick to the iron so that it can not well be removed, owing to the propolis that will always go in with the scraps. A dish of suitable size should always stand under the open end of the iron trough; and to keep the dish level I use square pieces of wood of different thicknesses, so that, by laying one on top of the other, any elevation of the back end can be overcome. To keep the scraps from sliding down into the dish of wax, which they are liable to do as soon as they begin to melt, where the elevation of the back end is great, as it has to be in the fall of the year, I cut a piece of wire cloth so that the edge of the wire cloth will fit the hollowing iron trough, after which this wire cloth is nailed to two suitable-shaped pieces of board, or pieces of sections, when a wire is attached to each piece of section, when the other end is bent at right angles, so that they will drop into holes bored along the upper edge of the body of the extractor. By having these holes in different places this wire cloth is adjustable, so that, where but few scraps are put in at each melting, they need cover but a small part of the iron trough. Having got out several lots of wax in varying amounts, I remelt it and cake it in 3-lb. cakes, straining it so as to take out all impurities, as I do so. In doing this I allow 2 oz. for the impurities, putting 3 lbs. 2 oz. each time into the extractor. For a strainer I use two thicknesses of cheese-cloth, fixing this cloth over a wire bent so as to form a hoop 5 inches in diameter. By drilling two holes at the right place in the front edge of the trough, and passing two wires around the strainer wire, and up through the holes in the trough, the strainer is drawn up so it will not be down in

the wax, and is held thus by bending the wires over the front edge of the trough. In this way I not only save all the wax made in the apiary, but I let the sun put it in the best of shape for the market, or my own use.

In conclusion I will say that very little if any thing about this solar wax-extractor is original with me, but was made to suit me from little items I picked up here and there regarding them. I think I got the most of my ideas from the writings of G. W. Demaree on the subject. The size given is plenty large for 100 colonies, but the dimensions can be varied to suit the wants of any one. G. M. DOOLITTLE.

Borodino, N. Y., Oct., 1890.

You will see by the engraving above, friend Doolittle, that we have made a little neater job. There are fewer pieces; being dovetailed at the corners, it is stronger; the glass-frame is easily removable, and the whole thing, when covered, is complete without any projections, save the supporting legs to hold it at an angle toward the sun. The size is a trifle different, as we made ours to take a 14x28 glass—a size that can be obtained at any hardware store.

Now, friend Doolittle, instead of going to work and giving so many pieces of so many different sizes, I would recommend the one who contemplates its construction to make a plain box whose inside dimensions shall be 14 inches wide, 29 inches long, and 7 inches deep. The sides of said box (not the ends) are to be rabbeted $\frac{3}{4}$ inch deep and about $\frac{1}{2}$ inch wide to receive the glass-frame. The cover should be a similar box, but only $1\frac{1}{2}$ inches deep, of the same dimensions otherwise, and is likewise rabbeted on the side rims. You will thus observe that the glass-frame 29 inches long and $14\frac{3}{4}$ inches wide can be let down into the rabbet into the box, and that the cover slips over the whole thing, and makes a complete and neat box. The legs are $17\frac{1}{2}$ inches long, and are pivoted with a screw, as shown in the engraving. The dovetailing is not essential, but as it costs us no more we make it so.

The pan is simply a trough made of Russia iron, one end of which is closed up, and the sides are bent over a little bit so as to rest on the rabbets in the sides of the box. The wire screen is fastened about $\frac{3}{8}$ of the way down, as shown in the engraving, or just far enough to admit of a Langstroth frame. I would suggest, that in telling how to make a hive or any other similar box, we give its inside length, depth, and width, and he who constructs it can then with less mental effort tell how to make it.

I have carefully tested your solar wax-extractor, and feel very sure it is very much superior to the one we have formerly advertised. It doesn't clog up, and the wax, when it melts, runs down an inclined plane, runs through the screen, and finally into the pan, and the pan is allowed to stand in the direct rays of the sun, the wax is kept liquid during the entire day, so that all foreign substances will settle to the bottom. E. R.

A VALUABLE LETTER FROM CUBA.

CUBA VS. CALIFORNIA.

Friend Root:—As so many readers of GLEANINGS have written me about Cuba as a bee-country, I can do no better than answer through its columns, so that all can have a chance at the same dish. It would be quite impossible for me to mention all the advantages and disadvantages in one paper. One writes, "How does it compare with California?" In some respects there is a similarity—that is, in the amount of honey, for instance, that is often secured from a given number of colonies; but then, there is a want of comparison, too, for California of to-day is not what it used to be for honey-producing, as the fruit and vine industries have made such rapid strides in the last ten years that the bee-ranges in many of the honey-producing counties have been turned to vineyards and orchards, while here there is nothing of the kind. The hand of push, of progress, of go-ahead, that is bound to succeed, the hand that has characterized and stamped the American people as the most energetic in the world, is crippled here—broken, as it were. Not a muscle moves in the direction of "get there on time." But the natural resources remain *almost* untouched by the hand of man, and they are something wonderful. As an evidence, I will say that, while the last year has been the poorest for honey I have ever seen here (on account of so little rain), yet our 550 colonies have passed through the dry season (or dearth of honey) with very little help. We have fed only ten pounds to the colony; and had it not been for the fact that we had 300 new colonies to make, I do not think we should have had to feed half that amount.

Bee-keeping here requires attention. To care for 550 colonies in California is only pastime compared with here, and the whole United States is the same. There is some season of rest for the bee-keepers, but here there is not. From November until March is our surplus season. Well, there is no rest about that. Then comes requeening, and the making of new colonies if you have any to make. The hot weather is then upon you; and if there are any queenless colonies that are at all weak, the moths will probably eat up the combs; and I want to tell you that it takes a pretty strong force to stand off the moth in this climate, where it never freezes, but "eternal vigilance" will keep them out.

Any one, to keep bees here successfully, must attend strictly to business. There is no time to go visiting, to hang around the corner grocery, or to sleep in the day time, but work and watch 365 days in the year, if there is no church to go to on Sunday, and there is not here. But for all the care necessary to success here, is it any worse than the life of the merchant? If he succeeds he must tend to business. How would it be with you, friend Root, if you or some competent person were not on duty all the time? How long would your business be self-supporting? I guess not very long. The same with bee-keeping here. It will pay if attended to. You don't see me running up the white flag. I tell you, that, if I do not succeed, it is my own fault. The conditions necessary to success are here; and if I do not avail myself of those conditions I have no one to blame. Of course, there are some requisites necessary to success, such as the right strain of bees, hives, fixtures, etc., suited to the wants here for a large business; but the bees, the right strain, are very important. We have the best results from the hybrids, one and two bands.

One correspondent asks, "What is the cost of starting an apiary of 550 colonies there?" That

is a hard question to answer. This establishment cost \$10,000. How much cheaper one could start such an apiary would depend upon the man's ideas of what is necessary. There have been some apiaries started here that I presume did not cost \$1000; but I think they have never amounted to much, or, at least, I have never heard that they did. If I start more apiaries it will not be with a view to see how cheap it can be done, but how complete an establishment for the care of 600 colonies can be made to successfully care for all the details, with as little help (man power) as possible.

There was one young man wrote me for my opinion of the two sections, California and Cuba, for bee-keeping, and gave his address as Orange Co., Florida, no postoffice. I could not answer with such an address as that. The letter would only go to the dead-letter office.

You will remember I told you last spring that I had a 5-to-1 gear for my Stanley extractor. Well, I have it now, and it works like a charm, when, before, the operator had to make his hand go around so fast, in order to properly dry the combs, that it was very tiresome indeed; and even then it could not be done to suit me. Now, it is no trouble with the 12-inch crank. You move the hand around slowly and deliberately, and the baskets are traveling as though they were afraid they would miss the train. The throwing-out of the honey now is a pleasure, while before it was a task that but few had the strength to perform. Yes, it starts a little harder; but when in motion there is no difference; but the difference in starting is more than made up by the slow motion at which the crank passes around. I shall do nothing wrong if I say to every one thinking of coming to Cuba to keep bees, that, if they wish to come, there is nothing in the way; that there is plenty of territory that is not occupied, and, in fact, the best part of the island, for bee-keeping, is still open, to be occupied by whoever wishes. With attention, more money can be made from bees here than in the United States; but let no one forget that there is no season of rest, from one year's end to the other, if he would do justice to the business, and make it pay. Many object to sticking so close to bees. That is all right; such people are not obliged to stick to bees. As for myself, I like my business, and I like to attend to it, and I have yet to see the business that thrives when it is neglected. The business is so unlike what it is in the United States that people fail to understand the difference without experience (and some not then). Here, in order to make the business pay, we are obliged to keep large apiaries; and, with large apiaries, the per cent of loss from colonies getting queenless is great; and if left queenless only a very short time, the combs are destroyed by moth, and many other little things that contribute to loss, where there are five or six hundred colonies together, that would not happen with a few colonies. All details need the closest attention. But with all the objections that come up against the large apiary I will take it every time, and give the one my best attention, rather than have five or six little bunches located in as many different places, as long as there is plenty of forage in one locality for the whole. This is the 23d of October; and with 550 colonies here in one apiary, the best are storing honey right along, and we are taking it away—a thing I never did in October before in Cuba, and you will remember that this is not one of the months we expect our bees to store surplus. This has been a very poor year. The Cuban bee-keepers in this locality have lost most of their bees. Very little rain indeed.

A. W. OSBURN.

Punta Brava de Guatao, Cuba, Oct., 1890.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

QUESTION 172. *Which will do the best work—a colony allowed to swarm (counting in the work of the swarm), or one kept from swarming by having its queen caged or removed?*

I believe one allowed to swarm.

Ohio. N. W.

A. B. MASON.

In an average season, one allowed to swarm.

Illinois. N. W. C.

MRS. L. HARRISON.

The colony allowed to swarm, if managed right, I think will give the best results.

Ohio. N. W.

H. R. BOARDMAN.

This depends. I should usually prefer no swarm if the colony kept actively at work.

Michigan. C.

A. J. COOK.

A colony kept from swarming does the best work, every time. But I want no queen caged nor removed.

Ohio. S. W.

C. F. MUTH.

The one allowed to swarm, if managed rightly. The management to keep from swarming is why the latter is not so good.

New York. C.

G. M. DOOLITTLE.

Ordinarily, where the working season is sufficiently long to allow the swarm to get into good working order for the main flow of honey, the swarming colony is best.

California. S.

R. WILKIN.

We are opposed to natural swarming, but we do not cage nor remove the queen. We give our colonies empty combs to prevent swarming. But the hives generally used in this country are too small for such a purpose.

Illinois. N. W.

DADANT & SON.

If there is a heavy fall crop, the swarmer might do best. In my locality I would risk the one made queenless, but I'd much rather risk one with a queen, if it took no swarming fever all summer.

Illinois. N.

C. C. MILLER.

I think the colony without the swarm. Use a hive large enough to accommodate the increase, and give them all the room to work in the one hive, with all the combs they can use for honey and brood, and then extract.

Wisconsin. S. W.

E. FRANCE.

That depends on what is meant by the "best work." If the question means what it says, the former. If the *most* work is meant, that depends on the season, locality, character of honey flow, etc.

Illinois. N. C.

J. A. GREEN.

This is a knotty question. I can't answer it, as there are so many variations in seasons and localities. I have experimented much in this line, and am not fully decided yet which is best. I hope to learn something this year more definite.

Vermont. N. W.

A. E. MANUM.

All depends upon the locality; that is, on the time of blooming of such flowers as you depend on for your surplus crop. I think that is the rule in most localities (counting the value of the increase), that the increase method is the

best. Now, remember I do not say this to any person having a practical, mechanical method of preventing increase which is safe and sure; but as no one has, so far as I know, I will let the answer stand.

Michigan. S. W.

JAMES HEDDON.

That will depend on the season and pasturage. If white clover is the only source of surplus, it is possible that the colony that does not swarm may gather the most honey; but if the honey season is a long one, with a favorable place for fall flowers, the colony allowed to increase will be far ahead.

Wisconsin. S. W.

S. I. FREEBORN.

I do not believe in caging or removing queens to prevent swarming. It has always seemed to me like adopting a worse evil than the one we fly from. For extracted honey we find there is no necessity for removing the queen. If running for comb honey, we would allow the swarm to issue, and manipulate so as to give the new swarm all the working force.

New York. E.

RAMBLER.

This will depend on circumstances—principally on the honey harvest, whether early or late, and whether you remove and return the queen at the proper time. Caging the queen in the hive is a lazy substitution, and will not kill the swarming fever. I have said that a swarm without a queen would work with greater energy than one with a queen, but having a desire to swarm. I repeat this, because I have been misquoted.

New York. C.

P. H. ELWOOD.

I do not practice the method referred to, and therefore can not say how far it succeeds and how far it fails. I suppose, however, that the relative crops of colonies which do not swarm, as compared with colonies that do swarm and colonies that are divided, is what the questioner is after. Where the surplus season closes early in July, the most may be expected of colonies not increased—yet with many exceptions. Where good heavy runs in August and September occur, the most may be expected from colonies that increase. One year of my bee-keeping, the yield per colony was three times the usual average. That year I increased 17 colonies to 72. The best yield was from a colony made into seven by division—they raising their own queens.

Ohio. N. W.

E. E. HASTY.

These answers are interesting, and I believe P. H. Elwood hits the nail on the head when he says that a swarm *without* a queen will work with greater energy than one *with* a queen having a *desire* to swarm. Granting that bees will work more energetically after they have swarmed, and are in their new home, it is very possible that the same bees have lost time just preparatory to swarming, and while the swarming impulse was upon them; and Mr. Elwood's point is, that, if it should be taken away from them entirely, they will average better. This is an exceedingly interesting and practical question, and if swarming can be controlled in some such way in out-apiaries, as Mr. Elwood and Hetherington do, it means that we can dispense with hired help to watch them, or, in the absence of such help, the loss from runaway swarms.

E. R.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

JUST AS MUCH HONEY STORED ABOVE THICK-BARS AS ABOVE THIN ONES.

Well, Uncle Amos, I have come to tell you about my thick top-bars, as I agreed to at the close of the season. I have taken off all the supers on the 29 hives that I told you about in August GLEANINGS, page 602. The different top-bars on the 18 hives that I spoke of in the same article do not satisfy me at all, so I will say nothing about them, only that they were a failure so far as preventing burr-combs is concerned; but with top-bars $\frac{3}{16}$ thick and $\frac{7}{8}$ wide, and spaced $\frac{1}{8}$ with the furniture nails, has given me entire satisfaction. There was not a particle of burr-comb, except on two of the colonies, and only a very little on them.

In your foot-note you ask me whether the colonies with thick top-bars stored less honey than the colonies with thin top-bars. Well, I am sure that I could see no difference. It is my opinion, from what experience I have had, that, if the colonies were strong, and there were a good flow of nectar, the top-bars, or even the honey-boards, would make no difference in the amount of honey stored.

On page 659, C. C. Miller wants to know whether there isn't danger of running fixed distances to extremes. I wintered two colonies last winter on their summer stands, with this close spacing, and they were in as good shape in the spring as any I had, and gave me good strong swarms. I use a device similar to the Hill, covered with burlap and chaff cushions. One thing that Dr. Miller speaks of is to tip the hive up and look at the bottom-bars to see how irregularly they are spaced. This is a point that we certainly have got to overcome if we use close spacing. I have been very particular to have my frames hang so that the spacing would be the same at the bottom as at the top; but I find that I have one frame in one hive that got a little out of "whack," and, as Dr. M. says, there was no brood reared on one side of the frame; but if I could get some of those wires that Dadant & Son describe, bent to fit my frames, I think they would fill the bill.

Maple Ridge, Mich., Oct. 21. FRED C. SMITH.

THE DOVETAILED AN OUTDOOR WINTERING HIVE; HOW IT MAY BE DONE.

Friend Root:—I am using a hive for wintering on summer stands, that I think is ahead of any thing I have ever seen, for reasons you will readily understand without explaining.

I use the common Dovetailed hive, and line each end with building-paper. I have the blocks and thumbscrews in the hive exactly like the Heddon. I use, also, eight closed-end frames, and hang them.

To prepare for winter I remove two combs and insert chaff dummies, one on each side, and screw up the thumbscrews tight. I have the closed frames pressed together tight for one end, wall-paper lining between them and the hive-walls. The chaff dummies are fitted tight to the end of the frames by pressure with a dead-air space between the dummy and hive-wall. A cushion laid on top of a Hill device, furnishes the winter preparation. Your bees are snug and warm for winter, and how they will build up in the spring! Now, this is good; it is cheap; there is no loose packing nor clumsy hives.

CLOSED-END FRAMES HANDLED AS EASILY AS ANY.

I would not use a hive without closed-end

frames. Objections to them have been made by men who never tried them or did not know how to use them. The closed-end frames have so many advantages that they will never be laid aside by any man who knows how to use them; and when hung from above, a man must be very careless or ignorant if he kills bees in manipulating them. I know this hive and closed-end frame is a good thing, and seems to be about what Ernest is trying to get at, so I send this description, hoping that it may be of some service to him in his search for a summer and winter hive.

J. RICHARDSON.

Moberly, Mo., Oct. 6.

Friend R., the plan you give has been given over and over again through our journals, especially years ago, about the time chaff hives were first inaugurated; but although such protection is a good deal better than none at all, during very severe winters the results have not been equal to such protection as was given by the chaff hive, or something equivalent to it. Of course, closed-end frames would be an advantage with such an arrangement.

PERFORATED ZINC FOR EXTRACTING, A SUCCESS.

Last year (1889) my bees swarmed a good deal. I hived them in 8-frame L. hives. They built, on an average, $1\frac{1}{2}$ to 2 frames of drone comb in the bottom, and nearly all drone in top story. I had no combs or foundation to give them, and they raised solid sheets of drones, at a considerable loss of time and honey.

This year I went over the yard, fitting in worker combs in place of drone in the brood-chamber, placing the drone comb in the second story, with a sheet of perforated zinc, Root's make, between, on 28 colonies. On looking them over soon after, I found two queens above, which I put below. One of the queens I found above, two or three days afterward. The others all worked well, very few drones below. In some hives the bees would clean out a part of one or more combs (drone) in upper story for the queen to lay in; but when honey came in fairly they would fill it up. In a few of the sheets the perforations were partly filled with wax; but combs in the upper story were not fastened down to the zinc where a $\frac{1}{8}$ space was used. I believe they are just the thing for hives for extracting, especially where the bees build all their comb; and they will pay expense and trouble of adapting them to the hives in one season's use.

KEROSENE FOR PROPOLIS, ETC.

I think the best and handiest way of getting propolis off the hands is to have a small can of kerosene handy. A few drops will "cut" the gum very satisfactorily. It is also good for rusty saws, etc. By running the bottom of the Benton queen-cage over a cutter-head, cutting $\frac{1}{16}$ deep and to within, say, $\frac{3}{8}$ of each edge, and tacking on a strip about $\frac{1}{8}$ thick by width between strips and length of cage, using about $\frac{3}{8}$ wire nails, the said cage can be used to introduce, the same as a Peet cage. To take off the bottom, pry up the bottom $\frac{1}{16}$ inch, using a stout knife; push the bottom back, when the nails may be easily pulled out. The strip or (bottom) will slide easily between the side strips, and may be used and put on the combs the same as the Peet. While, if any prefer to introduce by the candy plan, there is nothing to prevent by making cages this way: the wire cloth and top may be nailed on, and the bottom left until after the queen is caught before fastening. This idea may be old; but I, at least, have not seen it.

Port Orange, Fla., Oct. 14. JOHN B. CASE.

WATER FOR BEES: HOW TO MAKE THEM LET YOUR NEIGHBORS ALONE.

I will come to you and Mr. John Burr's relief about giving bees water, page 713. To keep bees from bothering your neighbors and yourself, and at the same time give the bees just what they want, give them salt water. As soon as the bees commence to fly and breed up they require salt; and I know if it is properly applied it will cure such diseases as foul brood. For watering bees, fill a nail-keg nearly full of sawdust; set it on a grooved board, with cleats nailed at each end to keep the water from running out. Place the keg one foot or so from the ground, under the eaves of some building in a warm and sheltered place. Throw in a handful of salt every other day; and if it does not rain, turn two or three quarts of water on the salt. In dry weather they will take more water; and if you have never tried it, or something of the kind, you will be surprised how many bees will work on it at all times of the day.

Bees go into winter with plenty of honey, but of poor quality. Look out for a loss this winter in New York. I have 600 packed for winter now.

W. L. COGGSHALL.

West Groton, N. Y., Oct. 4.

SPANISH NEEDLE AS A HONEY-PLANT.

Within is what is called here stickweed flower. This is not more than half of the top in length. I had to cut them to suit my box. These were gathered right after a hard rain. The bees were thick on them when I gathered them. You ought to be here to see those black bees hustle out before daylight, and come in so heavily loaded they drop all around the hive. Please give me the proper name of these flowers. I will send you some seed this fall. They commence to bloom about the 20th of August, and last until after frost, up to October.

Brush Creek, Ky., Sept. 10. D. H. WEBB.

Friend W., the plant you send us is the well-known Spanish needle—*bidens*. In localities it furnishes great quantities of honey. We have had no report before that bees worked on it directly after a heavy rain. It must be yielding tremendously in your locality. It has been said, that a bee-keeper should locate where there is very rich soil and very poor farmers, in order to get honey from this plant, for its favorite place is poorly cultivated cornfields. See what is said elsewhere about Spanish needle on the rich river-bottoms of the Illinois and Mississippi Rivers.

THE DOVETAILED HIVE: HOW TO MAKE A WINTER HIVE IN KANSAS.

Having just begun last spring to learn to take care of bees, and having purchased 10 colonies in Dovetailed hives, I have been watching for instructions for wintering. In this latitude there is so much mild weather that it would be difficult to keep a cellar at the desired temperature for bees. Then, too, there is sometimes extremely cold weather for several days, followed again by warm winds. I do not like the thin-shell idea of strengthening the credit of the Dovetailed hive—not if the thin shell is put on the outside; but to place thin followers on each side, inside the hive, and a chaff cushion on top, is about the simplest thing to do. The A B C book says four to six frames are enough; and even if seven frames are left, there is room for a half-inch follower on each side. This is just what I settled down to: I removed one or two frames from each hive; and to those needing more supplies I uncapped one or two frames of

honey and hung them over night in the second story, just drawing back the burlap at one corner, for the bees to get up. They did not fail to carry it all down in a single night, and a frosty night at that.

I have 13 colonies in the Mitchell hive, which is 25 inches long inside, and deeper than the Dovetailed. I shall cut these back as soon as I can drive the bees next spring into Dovetailed hives. They will make nine-frame hives, leaving room for a follower. I exhibited a Dovetailed hive at our county fair, and I learn to-day that it took the premium.

EZRA YODER.

Paola, Kan., Oct. 21.

LETTER FROM FATHER LANGSTROTH.

Dear Friend Root:—In reply to your letter, inclosing a check for \$50, sent to me by request of the N. A. Bee-keepers' Association, recently held at Keokuk, I would return my sincere thanks for their very kind and helpful remembrance of their old bee-keeping friend. I am still in a feeble and suffering condition, although much better than I have been for nearly two years. Thanking you for your many acts of kindness in the past, I remain

Yours affectionately,

L. L. LANGSTROTH.

Dayton, O., Nov. 7, 1890.

CALIFORNIA ROBBER-FLY.

I regret to say that the sand-bees and mosquito sent by J. C. McCubbin, Selma, Cal., were ground to powder, and so can not be identified. I wish all would send insects in strong boxes, tin or wood, wrapped in cotton, then they come in good condition. A small tin box, like a cap-box, will go for a cent.

The large insect which was carrying the bee is an asilus fly, new to me. I wish it were not broken. It is one of the robber-flies. I have illustrated several in my *Bee-Keeper's Guide*, from which figures this could be easily identified. These bee-killers are usually gray and sober colored. This one is ornamented with brown, and is quite handsome. I should like very much to receive a perfect specimen. There are several of these bee-killers in the South, and it seems that California is not exempt. I hope that Mr. M. will try again, when I shall hope for better success.

BATS.

Mr. Thaddeus Smith, Pelee Island, Lake Erie, Ont., Can., wishes me to name a bat which he sends me. This bat is large, quite whitish, so that it is called the hoary bat. The scientific name is *Vespertilio pruinus*. It is not very common, and is easily told by its whitish appearance, and a yellowish band across its throat. I was glad to get the specimen, as we had none in our museum. Bats often collect in great numbers in caves, where they domicile in summer and hibernate in winter. Bats are nocturnal, and feed on insects; so they are our friends.

CROWN BEARD.

Mr. Lewis K. Smith, Gainesboro, Jackson Co., Tenn., writes me regarding a plant which he says grows abundantly in his vicinity. The bees gather most of their fall crop of honey from it. He asks for name. I have never heard of this plant as a honey-plant before, I think. It is crown beard, or *Verbesina occidentalis*. It is closely related to beggar-ticks—*bidens*—and wild sunflowers. Indeed, it is next to the *Actinomeris Squarrosa*, which is much praised as a valuable honey-plant in West Virginia. No wonder that it affords honey. Many of its near relatives do so.

A. J. COOK.

Agricultural College, Mich., Oct. 27.

OUR HOMES.

Call unto me, and I will answer thee, and show thee great and mighty things, which thou knowest not.—*Jer. 33:2.*

The question oftentimes comes up, "Have we a right to expect that God will answer us when we come to him in prayer, asking him to direct us in regard to some matter on which we are undecided?" We often feel at a loss to know just exactly where duty calls us, or, in other words, we wish to know just what God would have us do in regard to certain things. This matter has been on my mind more or less through all my experience as a Christian; and sometimes I have not only been puzzled but considerably troubled because those who seem devoted and willing make sad mistakes. In looking back through my own experience I have, however, been led to decide that, where we go to God in prayer about a thing, and then make a mistake, the fault is ours, and not that of the Judge of all the earth, nor is any thing amiss with any of his promises in his holy word. We are very anxious to do a thing. We pray over it, and then watch for some indication that God approves of this very thing. We delude ourselves in the belief that we have prayed over the matter in question, and that God said it was right, whereas *inclination* swayed our better judgment to such an extent that *self* said it was right, and not the promptings of the Holy Spirit. The trouble is, even while we prayed we were not in a spirit of entire submission to his holy will. We should be very careful in such matters. The attitude of our heart should be, "Here, Lord, am I, ready to obey, and listening for that still small voice to direct me. I am willing to sacrifice property, to bear toil and pain, if I can only be sure that such a course is exactly what thou wouldst have me to do." After having done this we need to be very careful that we are entirely submissive and unbiased. We need to be sure that our inclination does not at all enter into the final decision. If we do this, I am sure the promise in this little verse of our text will be fulfilled, and that we shall seldom if ever have just cause to regret taking the course we did.

When the time came around for the International Convention, it seemed almost folly for me to think of deserting my post. Our new factory was just roofed. The doors and windows were not in. Machinery was to be located, and important matters were to be decided, not only day by day, but hour by hour. Things were to be located that would be exceedingly hard to move if a mistake were made. Expensive men were on the ground waiting to be directed. How *could* I be gone five full days? I decided, for a couple of weeks before the time appointed, that it was not my duty to go. A good many would be thrown out of employment if I were absent. In talking with my pastor about it he gave me an idea, that at first I accepted as a jest or a piece of pleasantry; but afterward I decided there was an important truth in it that I specially needed. His suggestion was something like this: "Why, Bro. Root, you can solve the problem this way: Let your men have a vacation while you are gone; and if they can not well afford it, just keep their pay going all the same." While I am about so as to see most of my hands every hour or two, I can so direct them that their work is done properly. If I am absent, a good deal will necessarily be done in a wasteful or unprofitable way. This is true of any man who neglects his help, or who does not provide competent overseers. The friends here at home are exceedingly ready and willing

to do as I wish; but the trouble is, when I am absent they do not *know* my wishes, and can not well know all the plans I have in mind. Therefore, in order to go away I must make up my mind to accept, as a matter of course, more or less unprofitable work, and perhaps also have more or less useless labor performed. As a rule, I think every man's first duty is to look after his own affairs. Why, even the Bible enjoins that. In Proverbs we read, "Seest thou a man diligent in business? he shall stand before kings, he shall not stand before mean men."

Three or four days before the time appointed, I began to pray very earnestly on the subject, asking God to tell me where duty lay; and I remember telling my wife that I felt sure my prayers would be answered—that is, it would be impressed on my mind whether I ought to go. For several days it seemed as if no light were to be given in regard to the matter. I could not see that the Holy Spirit dictated or impressed my mind either way. If it would not sound irreverent, I could have told the honest truth by saying to my wife, "So far God has said nothing to me about it." I should not like to use such an expression, however, for fear that many of my good friends would think me cranky. In fact, I should fear that I would be a little troubled about any of my friends if *they* should reply in just that sort of language. During the very wet fall that we have had, my wife and children have often asked me anxiously what the barometer said about the weather. A great many times I have replied evasively, or said nothing. But they often say, "Why don't you tell exactly what the barometer does say?" I reply, "For the simple truth that it does not say *any thing at all*. It neither goes up nor down, and I suppose we must conclude that the weather is to remain—at least for the present—just about as it is now." They have all learned to have *faith* in the barometer, for a great many times I have said to them, positively and decidedly, "The sun is surely coming out; and from the manner in which the mercury rises, and the rapidity with which it goes up, you will certainly see clear sky before noon, and I shall be much disappointed if we do not see it come out in a couple of hours." When I have time to keep my eye on the barometer, so as to watch it and give it a thump every hour or two, it is very rare I make a mistake. Now, friends, you have a good illustration right before you. Can we depend on the promptings of the Holy Spirit in the same way, or in a like way that we depend on the movements of the column of mercury? I think we can, and it gives me pleasure to say this. I have been thinking over it for several days, whether it were right and proper for me to tell you this, and to state it just as I have said it above; and I rejoice to feel, right now while I am talking, that the Holy Spirit says in my heart, "My child, you are safe and right in saying just what you have said. It pleases me to have you exhort your readers to *have faith* in just this way." Shortly before it became time to make preparations for my absence, I began to feel very plainly that God called upon me to go. The Holy Spirit seemed to direct that I should make arrangements according to the best of my human wisdom for work while I was absent, and then to drop care and anxiety, and leave home with an untroubled spirit, asking constantly for direction as to what I was to do. We have an illustration in the book of Acts. You will remember that Cornelius was sent to Joppa, to find Peter, who lodged with a tanner by the side of the sea. This man was to tell Cornelius what he ought to do. I have often thought of this passage. Does the Holy Spirit ever send us on like errands? I believe it does. Now,

please do not imagine, dear friends, that I had any idea in mind that there was any special great thing for me to do away off in Keokuk, Iowa. I only felt that it was God's wish that I should be present with the rest of the brethren, and do what I could to help matters along, and possibly to do something in a quiet and natural way for Christ Jesus.

No doubt this prompting of the Holy Spirit came through natural events and human agencies a good deal. Three different friends wrote they were looking forward with great pleasure to the time when they would shake hands with their old friend A. I. Root at the coming convention. Then when I thought of being absent, something seemed to tell me that I was doing wrong, and it began to lie as a heavy weight on my conscience; and when I considered the matter of changing my plans, and of going after all, peace and happiness began to come into my heart. For quite a time after leaving home I did not feel any enjoyment at all; but I decided that I would do my duty as well as I knew how, whether I enjoyed it or not. And I think, dear friends, this is one of the very best ways to secure the peace of God. Make up your mind that inclination must give way to duty, peace or no peace, and God will send the reward in his own time.

One of the first disappointments was to find that, when we arrived at Elyria, the Lake Shore train was two hours late. We did not know whether Dr. Mason expected to attend or not; but I invested 25 cents in a telegram. This telegram had the effect of waking him up, and of bringing him to the depot, even after he, like myself, had decided not to go. When we were within perhaps a hundred miles of Keokuk, a stranger sat down near us who eyed me very intently for some time. I finally asked him if he was not one of the bee-keeping friends on the way to the convention. He replied that he was, and added, "Are you not A. I. Root?"

I nodded assent. Then he said, "My name is Draper."

"A. N. Draper, of Upper Alton, Ill.?" said I, interrogatively.

He nodded, and we were old friends at once. Friend D. used to write for the *American Bee Journal*, before GLEANINGS had an existence. He had followed me, even to covering my beehives with stable manure, as I did years ago; and then he afterward put his bees in a cold-frame, as a good many others did in those old times. He risked all he had in the venture, then gave up bee-keeping in disgust, as he lost all. But, like a good many others, he came back again to it. Pretty soon another friend who lives on the banks of the Illinois River, Mr. J. M. Hambaugh, of Spring, Ill., came in. This latter friend had secured about 10,000 lbs. of Spanish-needle honey, gathered from the lowlands along the river. In his market, the honey from Spanish needle is now selling more readily, and is giving better satisfaction, than even white clover. It is of a beautiful amber color, and I think it is often sold as goldenrod honey.

The convention was one of the best I ever attended. The attendance was not only large, but our Western friends came and handed in their dollars in order that they might become members, more generally, I think, than in any other convention I ever attended. Perhaps I might mention right here, that one of the troubles in our conventions is in this very line. A good many attend every session, take great interest in the proceedings, and sometimes take part, to a considerable extent, in the debates; yet when the call is made for the necessary funds to keep up the necessary expenses, in many localities there has been a considerable

hanging back. Dr. Miller, Dr. Mason, Prof. Cook, and others, have urged so hard that every one should hand in a dollar that sometimes we have almost had hard feelings in regard to the matter. If we move our national convention all over the United States, or, at least, over a great portion of it, as we have been doing, it happens, as a matter of course, that a great part of the members (and oftentimes the presiding officers) are made up of people who never attended before, and perhaps who may never attend again. This seems a little unfortunate; and yet if all parts of the United States are equally represented, it must be so to a greater or lesser extent. During this last session, arrangements were made whereby we might have a certain number, at least, who would be members year after year, whether they could be in attendance or not. This is secured by making anybody a life-member on the payment of \$10.00. If I am correct, the editor of the *American Bee Journal* was the first one to pay \$10.00 and become a life-member. Ernest and I have also agreed to become life-members, and I said at the convention that I thought the United States should furnish at least 25 who would pay a like sum, and hereafter be members for life. Now, then, who is there among our readers who is ready to stand by us for the purpose of making a permanent institution of the North American Bee-keepers' Society, as it is to be styled, in order that it may stand on a permanent basis, and not be left to be blown about by the wind, and dry up and die like autumn leaves? It is proposed to have it incorporated according to the laws of the United States, and it seems to me this would be a very sensible and wise proceeding. Further particulars in regard to the matter will be found in the *American Bee Journal*, as also a full report of the proceedings of the convention, which we do not give here, as we do not wish to have our pages contain something that most of our readers will see in the *American Bee Journal*.

I hope I may digress enough right here to urge every reader of GLEANINGS to subscribe for the *American Bee Journal* at once, if he does not now take it. Its editor has perhaps done more to keep up our conventions, report their proceedings, and labor for the general interest of the bee-keepers of America than any other one among us. The field occupied is so different from the one covered by GLEANINGS that you will not find much repetition if you take the two.

Now for the promise in our text. I soon began to realize why it was that God wanted me to go to Keokuk. A good many of the friends who were there had taken GLEANINGS almost since the time it was printed by windmill power. They knew me better than they knew their next-door neighbors, many of them, and they wanted to see me and shake hands. Perhaps some who have followed me all these years came more to see me than for almost any thing else. Please remember that I do not say this boastfully, but to show you that I should have been sadly out of place, and lacking in friendly, brotherly spirit, if I had allowed anything to keep me away from such a gathering. I did not realize it fully until I came to read my paper. As it is hard for me to speak to a large roomful, I told them, before I commenced, that I should consider it a great favor if they would come up and occupy the front seats, so that we might have it more like a family gathering. Our good friend Mrs. Harrison started the movement by picking up her chair, and bringing it quite close up to the speaker, when there was a general move to following her example.

During the reading of my paper (see Our Homes, last issue), when I came to speak of

God's gifts to bee-keepers I digressed from my reading long enough to mention the Spanish-needle honey I had been told of (samples were on the table at my side) on the banks of the Illinois River, and suggested that God's gifts were many times lying near our own doors, unknown and unappreciated. A lady in the audience suggested there were untold acres of the same plant lying along the *Mississippi* River also. Somebody who lived further down stream gave us another corroboration of the statement, and pretty soon so many facts came in to support the spirit of my paper—have faith in God—that the president tried to call them to order. They had got to going, however; and in their eagerness to supply your humble servant with the facts he wanted, they forgot president, essay, and every thing else. Finally the president good-naturedly called a halt. Said he, in substance, "Why, who ever heard of such a thing as interrupting an essay to give your separate experiences? Let Bro. Root finish his paper, and then we shall be glad to have you discuss the matter to your hearts' content."

Some of them looked somewhat astonished, and perhaps a little put out, because they could not tell their story right then and there. But instead of feeling annoyed myself, it gave me a new thrill of joy to see how anxious these friends were to furnish me any information I called for in any particular line of our work. It touched me, too, to see how soon they felt acquainted with me, and treated me as if I were really "one of the family."

Later on, when they came to discuss important matters, I was surprised and astonished to see how eager and full of enthusiasm these Western friends were to understand more of the different questions that puzzle us in bee-keeping. As an illustration: The president asked for a show of hands in regard to the matter of using foundation—how many used it in full sheets? how many used only starters? how many practiced Hutchinson's plan of using only starters for hiving new swarms? how many used foundation in section boxes? Our good president, R. L. Taylor, seemed to have a happy faculty of bringing out all these points, and in getting every one in the room to have something to say in the matter, and at the same time not have valuable time wasted.

Some facts in regard to the value of sugar compared with honey for winter stores interested me greatly. President Taylor himself gave us the following most important item. Quite a number of colonies were fed on stores of sugar syrup, and an equal quantity were provided with stores of honey. The colonies were weighed, both in the spring and fall; and those having honey consumed nearly if not quite *twice* as many pounds of feed. I have been for years past fully satisfied that stores of sugar syrup are more wholesome, and a more concentrated food than any honey; but I was not prepared to find so great a difference. A great amount of questioning and experiences were given in this line, and the whole evidence seemed to be almost invariably in favor of sugar. A convention is the only possible place in which such a matter can be thoroughly discussed, and important facts like this settled. Bee-journals are good, and have their office, but we must have conventions also. I felt ashamed of myself for having ever entertained the thought that I might be excusable in staying away. At one of our temperance meetings some years ago, a reformed man told a little story of his soldier life. He said a young boy, who had enlisted contrary to the best judgment of his friends and relatives, once told his comrades that he was afraid he might show the "white feather"

in a coming conflict. Said he, "Boys, if you see any indications in me of any thing of the sort, I just want you to take me by the collar and straighten me up, and hold me to my post." Our reformed friend remarked that he wished the Christian temperance people to take hold of him in the same way, if he got back; and my feeling during that whole convention is just expressed in the above. If I should again show any such foolish, short-sighted disposition to shirk and stay at home, I hope some of my good friends will take me by the collar, and straighten me up, reminding me of this passage in this present paper.

I think I never saw more facts of importance brought out in so short a time. The bright and expectant faces, the brief, simple testimonies, and the general feeling of brotherly love, and desire to help each other, were really wonderful. Before I knew it I was enjoying myself most intensely. Those thrills of joy that I have told you about, began to come into my heart, wave after wave. There were not very many present who had read the bee-journals, and experimented with bees, as long as I have. Perhaps *none* had read so much voluminous correspondence, and this enabled me to furnish important connecting links here and there. There was so much interest manifested that the president found it hard work to get them to adjourn at dinner time. After the adjournment, of course a great many gathered around the Roots, both old and young. Ernest's visit through York State had made him acquainted, not only with the York State people, but with friends away out west as well. A good many were inviting me to go home with them, or to look at something. But a white-haired German friend, Weyend by name, in a sort of comic way captured and ensnared your old friend completely, by a few brief sentences. His invitation was worded something as follows:

"Mr. Root goes with me. I can show him artesian wells, where the water comes out so as to make a little lake."

He had been reading GLEANINGS, and he knew well where I was deeply interested, and was ready to take advantage of it. He continued:

"Yes, there are beautiful fish in the ponds around the wells, and I will show you where the water goes down the bluff and carries a water-motor that runs a dynamo."

When he spoke these words he looked at Ernest in a comic sort of way, as much as to say, "You see I am going to have Ernest too;" and in a little time a party was organized to go and see these wonders in the suburbs of Keokuk. If you look now at the words in the latter part of our text, you will see there a promise—"and show thee great and mighty things which thou knowest not." I wish I could give you a picture of our good friend Weyend. May be we will some time; but for the present we must content ourselves with a pen-picture. He is an excellent type of a good-natured, jovial, enthusiastic son of the "fatherland." His quaint, peculiar ways, win friends at once, and a sort of dry native wit soon sets his companions into fits of laughter that are almost uncontrollable. For instance:

"Why, Mr. W., you are taking us off top of a great hill. Surely the artesian wells are not up here, are they? What should put it into the head of any man to think of drilling a well on top of this great bluff?"

These wells belong to a wealthy starch-manufacturer, Mr. J. C. Hubinger. Friend W. explained:

"Why, Mr. Hubinger he has got lots of money, and he wanted a well right up there, and when he wants any thing he wants it *bad*!"

"No doubt he wanted it bad; but what assurance had he that he would find water to come even to the top of the ground, on such a great bluff as this—more than 100 feet above the waters of the Mississippi River?"

"Why, Mr. Hubinger he *got* to have it; and when he *got* to have a thing it *must* come, so he kept on drilling."

We soon came to one of the wells. There were three in all, and each one of them was sending out its treasures of water into beautifully paved and cemented reservoirs at our feet. One of the wells was in process of drilling; and as I approached the driller I asked, "How much water comes out of the top of this well in a minute?"

"About 900 gallons."

"How far down are you?"

"About 1820 feet."

I felt anxious to see what sort of rock came up, so I asked, "How often do you use the sand-pump?" thinking we might wait and see the operation, and see what would come out. To my surprise, however, he replied, "Why, we don't sand-pump at all. The stream of water which you see washes out all the sand and pounded rock; so all we have to do is to keep right on drilling until the drill is pulled up to sharpen it."

Now, friends, here is something intensely interesting. These vast streams of water that come out with such force as to go to the top of this bluff come constantly from fissures in the rock they are drilling, and these fissures are so frequent that all debris is washed out. We descended a bank, so steep that it made Dr. Miller puff and blow, and found, many feet below, almost on a level with the river, a *hundred-horse-power* turbine water-wheel. Another new water-motor was being put in place to give additional power. These water-motors carried the latest improved dynamos, and great wires ran up to the city to furnish electric lights. The artesian wells spout forth their treasures through the day-time, which is stored up in those large reservoirs, or miniature lakes, they might be called. When it gets dusk, the great valves are opened, and the turbines with their immense power propel the dynamos that send the stream of electricity up through the town.* Is it not wonderful? and does it not verify the promise of our text?

The next day we visited the Dadants, and saw their factory for the production of the beautiful foundation that rivals any thing else made in the world, and I had another treat. The Dadants have perhaps the finest factory for foundation in the world. Their output during 1890 was something like 85,000 lbs., while our own was only about 30,000 lbs.

"But why in the world, friends, do you not use steam power when you are doing so large a business?"

Our good friend C. P. replied:

"Mr. Root, there is just one thing that makes us hold on. A company is already organized, with a capital of two millions of dollars, to take the Mississippi River at the rapids you observed, and make it turn water-motors that shall move dynamos to send electricity all over the surrounding country, to furnish power wherever it is needed; and we would rather have a big wire, and have the power, rather

than to have a steam-engine and be obliged to haul coal away out here."

So you see, dear friends, what there is before us in the future.

You may perhaps know that a company has been incorporated under the laws of New York, and they have already begun the work of digging a very deep canal parallel with the rapids of the Niagara River, for the purpose of taking advantage of the great descent of the river here for about half a mile above the falls, and ending near the base of the cataract. When the full capacity of the fall is employed it is believed that it will be equivalent to 700,000 horse-power, and this at no expense save for repairs, as the supply is perfectly uniform the year round. To do these great things, however, we must work together. No man can accomplish any thing by being a Robinson Crusoe. All these great projects and movements are the result of the combined efforts of great numbers of earnest thinkers and workers. Friend Weyend gave us a bright illustration of his friend Hubinger, the starch-man. I do not know whether he is a Christian or not; but he shows an element of Christianity, in one sense at least. He goes down into those steep bluffs a quarter of a mile or more in pursuit of Nature's pent-up waters. They have utilized them by the most efficient water-motors known, and finally they set the water-motors to driving these wonderful dynamos, a project which is a result of the thinking and stirring brains of the present decade. Friend Weyend's comical "got to have it" expresses the energy and determination of the man. And is not the thought on a line with the Bible promise, "Seek, and ye shall find; knock, and it shall be opened unto you"? But to do this we must be in intimate partnership with our fellow-men. Conventions made up of people interested in special pursuits are on the highway to these attainments, especially where these conventions are opened with prayer, and interspersed with songs and hymns, as was every session of the convention at Keokuk.

Call unto me, and I will answer thee, and show thee great and mighty things which thou knowest not.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

That art on which a thousand millions of men are dependent for their sustenance, and two hundred millions of men expend their daily toil, must be the most important of all—the parent and precursor of all other arts. In every country, then, and at every period, the investigation of the principles on which the rational practice of this art is founded ought to have commanded the principal attention of the greatest minds.

JAMES F. W. JOHNSTON.

THE OHIO EXPERIMENT-STATION REPORT ON STRAWBERRIES.

This is sent free to every resident of the State of Ohio on application. Address Experiment Station, Columbus, O. We presume it will be sent to others for a couple of stamps, although we do not know. If any of you wish a report by disinterested parties in regard to all new strawberries offered during the past year or two, you want this report. Not only does it chronicle the tests on the Experiment Grounds at Columbus, but Prof. Green visited many of the leading strawberry-growers of the State, while the berries were fruiting. You will remember that he had just left Matthew Crawford's at the time I came on the grounds. It almost makes one smile to see how nearly their decision agrees with mine. For instance, in their Summary No. 2, we read:

The following varieties have been thoroughly tested, and are suited to the wants of those who

*Out on the hill before me, our big windmill is standing idle. It has filled its tank, and has been days and weeks waiting for a job. Well, all that is needed to let this windmill use its surplus power for lighting our house is a little water-motor and a dynamo to match. It will easily pump water enough during the day to run dynamos enough to light all the private dwellings in "Rootville."

FACTS! FACTS! FACTS!

'The Bee-Keepers' Directory, 125 pages, price \$1 00. **Thirty Years Among the Bees**, 82 pages, price 50 cts. **The Am. Apiculturist**, one year, price 75 cts. The above paper and books contain all the information necessary to produce honey by tons, and to rear queens by thousands. All mailed for \$1.25. Sample copies of Apiculturist free. Address

SPECIAL NOTICES.

POULTRY-NETTING ADVANCES DEC. 20.

Bear in mind, that only a little over two weeks remain in which you can buy wire netting at the present low prices. The 51st page of the new catalogue shows what the price will be next year. Notice the list of remnants on another page, which is subject to 10% discount before Jan. 1.

ORDERS FOR MACHINERY.

Some few orders for machinery have been somewhat delayed on account of the interruption and large amount of extra machine work incurred by moving into our new building. We are glad to say, however, that our workers in iron and steel are now nicely housed in a large airy room about three times the size of their former quarters, and will soon be in shape to turn out promptly all kinds of machine work.

A SECOND-HAND PLANER AT A BARGAIN.

We have on hand for sale a 24-inch heavy pony planer, made by Graham, of Rochester, in good repair. It cost new \$240; was used about three years in our works when we sent it back to the works and had it rebuilt new at an expense of \$50 and freight both ways. We used it only four or five months when we were obliged to put in its place a large double-surface planer to do our work. We offer the above machine, all ready to run, free on board cars, for \$150.

OUR PREMIUM LIST.

Some of you may be wondering what is keeping our premium list so late this year. The fact is, we shall not have any, but send you our catalogue instead. We shall offer special premiums from time to time during the coming months. For the present we wish to say that you may select any article in our catalogue as a premium; and each subscription you secure for GLEANINGS will count 25 cents toward the price of it, provided that in your list of names you have as many new subscriptions as renewals. Remember, the remaining numbers of this year after the subscription is received are sent free to new subscribers.

DISCOUNTS FOR EARLY ORDERS.

By the new catalogue you will notice that the 4% discount we have been allowing the past month is extended to December instead of dropping to 3%. A good many are taking advantage of these early order discounts, and are sending us large orders. We are also shipping a number of carload orders to distant points. We have just shipped a carload of hives and sections to friend Ball, of Reno, Nev., who sent us the car of comb honey.

We are also loading a car of supplies for the Beekeepers' Association of Maricopa Co., Ariz., from whom we received a car of honey in August, and are daily expecting another. We have orders in for three or four more carloads for various points. We expect to load a car for Portland, Ore., within a month; and if any of our readers in Oregon or

Washington wish to secure carload rates of freight as far as Portland they should send their orders in at once. We hope, also, to make up one or more cars for Southern California within the next six weeks or two months at the outside; and if any in that section want to avail themselves of this opportunity they would do well to write or send their orders very soon.

NEW ENLARGED EDITION OF OUR CATALOGUE.

We have given our illustrated catalogue and price list a thorough revision, and added eight more pages of matter. In order that our readers may see what we have done, and be sure to have a new catalogue to order from, we are mailing a copy to each subscriber of GLEANINGS. If you fail to get it with this, or soon after, drop us a card and we will mail another.

I will briefly mention a few of the alterations, additions, and changes in price. The matter has been re-arranged a good deal; and in order that you may easily find any thing that you want, we have added a comprehensive index on the inside of front cover. The catalogue was formerly arranged with a view of making articles come in alphabetical order. This could not be strictly followed, as kindred articles, of necessity, must sometimes be mentioned together, though not beginning with the same letter. We have given up the alphabetical order, and arranged in a natural order, which you will notice as you turn over the pages. Notice the additional matter in the introductory pages, inducements to order early, and discount for so doing.

The following articles have been advanced in price: Perforated zinc and honey-boards, all kinds; Simplicity feeders; a few of the hives have changed in price. Tin separators, tin pails, tin plate, and galvanized poultry-netting are advanced. A number of new articles have been added, which we will leave you to discover.

The discounts for large cash orders have been abolished, and the discounts for early orders taken their place. You will observe, however, that the early-order discount applies only to such articles as we manufacture, found on pages 10 to 27 of the list. Much of the matter is entirely re-written. Some instructions are given in the matter of feeding and wintering. Further changes, especially in the Counter Store list, are anticipated. Any suggestions from our patrons that will lead to making the catalogue more helpful and convenient to order from, will be appreciated.

KIND WORDS FROM OUR CUSTOMERS.

GLEANINGS A PROFITABLE ADVERTISER.

I have been a constant advertiser in GLEANINGS for over four years, and can honestly say it is the best medium I ever used. C. M. GOODSPEED, Skaneateles, N. Y., Nov. 17.

MORE ADVERTISING THAT PAID.

I am well pleased with the results of my advertising in GLEANINGS. I am all sold out of queens, and sending back money nearly every day. I received enough orders to take all the queens I had left in four days after my last ad't was out, and I had quite a large number of them too. ELMER HUTCHINSON, Rogersville, Mich., Oct. 27.

A BIG BARGAIN FOR \$1.00.

SPECIAL CROPS, one year, \$1.00. MONTREAL FAMILY HERALD and STAR (weekly), \$1.00. GOLDEN CENSOR (Rockford, Ill., weekly), \$1.25. All of above one full year for \$1.00. Special Crops and either one of the others for 50 cts. This offer is good until Dec. 26. Renewals accepted same as new subs. Address C. M. GOODSPEED, Skaneateles, N. Y.

In responding to this advertisement mention GLEANINGS.

FOR SALE.

50 STANDS of bees; two Italians, others hybrid and blacks in 10-frame Simplicity and 8-frame Dovetailed hives. Price \$4 each.

J. HAMMOND,

Buena Vista, Scioto Co., Ohio.

In responding to this advertisement mention GLEANINGS.

Wants or Exchange Department.

WANTED.—To exchange apiary of 150 colonies of bees. Will take any kind of farm stock, goods or groceries.
ANTHONY OPP, Helena, Ark.

WANTED.—To exchange warranted Italian queens to be shipped early in June and July, 1891, for solo alto horn or tenor B-flat trombone. Write and give particulars to
JAMES WOOD,
22-23-d North Prescott, Mass.

WANTED.—To exchange forest trees, for strawberry-plants, grapevines, and all kinds of small fruit-trees or offers.
W. G. MCLENDON,
Gaines' Landing, Chicot Co., Ark.

WANTED.—To exchange Italian bees in L hives for beagle hounds, or will exchange fox-hounds for beagles.
J. B. MITCHELL,
23-24-d Hawkinsville, Pulaski Co., Ga.

WANTED.—To exchange Perfect Hatcher, 176 eggs, cost \$75.00; and brooder, 300 chicks, cost \$38.00; been used at fairs a little, for Italian or hybrid bees.
23-d ELIZABETH DIMICK, Burns, Alle. Co., N. Y.

WANTED.—To exchange one 6x9 self-inking press, with type, for 10-inch fdn. mill and wax-extractor, or better offers; also a 6-inch fdn. mill, for wax.
53-24-d L. L. ISENHOWER, Reading, Pa.

WANTED.—To exchange new hearse for bees, in good L hives, or comb honey.
23-d J. H. TATMAN, Connerville, Ind.

WANTED.—To exchange a Breed's Universal Weeder, used one season, price \$12.00, for new Simplicity or Dovetailed hives or offers.
23-d ELMER E. SHARP, South Greece, Monroe Co., N. Y.

WANTED.—To exchange bee-supplies for empty combs. Bee-friends, let us hear from you.
23-d J. B. MURRAY, Ada, Hardin Co., Ohio.

WANTED.—To correspond with parties who wish to exchange beeswax for supplies.
GEO. RALL, Frenchville, Trem. Co., Wis.

WANTED.—Apicultural offers in exchange for plain and fancy job printing.
23-24-d C. W. DAYTON, Clinton, Rock Co., Wis.

WANTED.—To correspond with parties having potatoes, onions, apples, and honey for sale. Prompt attention given to correspondence. Consignments solicited. Prompt returns made.

EARLE CLICKINGER, 121 So. 4th St., Columbus, O.

Job Lot of Wire Netting.

CUT PIECES AT A LOWER PRICE THAN FULL ROLLS.

Having bought from the factory, at our own price, five or six hundred remnants, as listed below, we are able to give you the choice of a great variety of pieces at the price of a full roll or lower. Full rolls of netting are 150 ft. long, and when they are out we have to charge nearly double the full-roll rate, because it is so much trouble to unroll, measure, and cut, and run the risk of having a lot of remnants on hand. No doubt it is in this way that the following remnants have accumulated. It costs a good deal to get all this in shape so we can easily pick out from the lot the piece you want. But to move it off quickly, we put the price down so you can all have a chance at it. Remember first come, first served. In ordering, therefore, name a second or third choice, or say that we may send the nearest we can if the piece selected is gone. On 5 pieces deduct 5 per cent, on 10 pieces 10 per cent. On all orders sent before Jan. 1, 1891, deduct 10 per cent. These remnants are shipped only from here. If any of you want to secure some, and don't want them shipped till later, when you will order something else, so as to save freight, pick out the pieces you want, send remittance with the order, with request to lay by till called for, and we will mark them as belonging to you. We prefer to ship them right out, however.

LIST OF POULTRY-NETTING REMNANTS.

Width in In's.	Size of Mesh.	No. of Wires.	Cts. per Sq. Ft.	Length of each piece. Multiply by the width in feet to get the number of square feet in each piece.

HONEY COLUMN.

CITY MARKETS.

ALBANY.—*Honey.*—Receipts up to date 1900 cases of comb honey, and 212 packages of extracted. The market is very quiet at present, and prices remain unchanged.
CHAS. McCULLOCH & Co.,
Nov. 19. 339 Broadway, Albany, N. Y.

CINCINNATI.—*Honey.*—There is a good demand for all kinds of honey. Arrivals are fair of all but comb honey and Southern extracted. Small lots only of each are arriving and disposed of on arrival. California honey seems to be as highly appreciated in our market as the best clover honey. We quote choice comb honey nominal, at 16¢@18¢. Extracted honey at 5½¢@8¢ on arrival. *Beeswax*, there is a good demand at 24¢@26¢ on arrival for good to choice yellow.
CHAS. F. MUTH & SON,
Nov. 12. Cincinnati, Ohio.

BOSTON.—*Honey.*—Fancy white one-pound combs selling at 19¢@20¢; fair to good, 17¢@18¢. No 2-lb. combs in this market. Buckwheat or off-colored honey not wanted at any price. Extracted selling at 7½¢@8½¢. No beeswax on hand. Demand good.
BLAKE & RIPLEY,
Nov. 19. Boston, Mass.

RIVERSIDE.—*Honey.*—Comb honey all shipped out of Southern California, and nine-tenths of the extracted. Latter selling in car lots to-day; white, 6¢@6½¢; light amber, 5½¢@6¢.
GRIFFIN & SKELLEY COMPANY,
Nov. 12. Riverside, Cal.

ST. LOUIS.—*Honey.*—We note an active inquiry for strained and extracted honey in barrels at 6¢; cans, 7½¢; comb, white clover, 18¢@18½¢; dark, 15½¢@16½¢. *Beeswax*, prime, 25¢. D. G. TUTT GROCER CO.,
Nov. 19. St. Louis, Mo.

SAN FRANCISCO.—*Honey.*—Extracted honey is very firm and advancing, with a heavy demand for Europe as well as for the East, and we quote now 6¢@6½¢ for eastern shipment. Comb honey is scarce, and wanted at 13¢@14¢ for 1-lb. comb honey, and 10¢@12¢ for 2-lb. comb honey. *Beeswax* is scarce, and firm at about 23¢@24¢.
SCHACHT, LEMCKE & STEINER,
Oct. 22. 16 & 18 Drum St., San Francisco, Cal.

DETROIT.—*Honey.*—The demand for comb honey continues good, and brings 16¢ readily if a fair article. Extracted, 7¢@8¢. *Beeswax*, 27¢@28¢.
M. H. HUNT.

Bell Branch, Mich., Nov. 20, 1890.

ST. LOUIS.—*Honey.*—We quote choice white-clover honey in 1-lb. sections, single tier, 18¢; fancy, 20¢; double tier, 17¢@18¢. Dark and broken to fair stock, 12¢@15¢. Extracted, in cans, 8¢@10¢; dark, 6¢@7¢; barrels, 5½¢@7¢, as to quality. *Beeswax*, prime, 25½¢@26¢; dark, less. The demand for honey is good, and the stocks here are very light.
W. B. WESTCOTT & Co.,
Nov. 24. St. Louis, Mo.

FOR SALE.—3000 lbs. light extracted honey in 60-lb. tin cans; and 800 lbs. nice comb honey in 12-lb. crates. Delivered on cars at 10¢ for extracted, and 18¢ for comb.
S. A. SHUCK, Liverpool, Ill.

FOR SALE.—One barrel of extracted honey, gathered mainly from false boneset and heartsease. This honey is well ripened and of fine flavor. Will take 8¢ per lb., f. o. b. here. Can put it up in 60-lb. square tin cans, at 8½¢ per lb. Cans are boxed two in a box. Correspondence solicited.
R. B. LEAHY, Higginsville, Mo.

WANTED.—Extracted honey, either white clover or linn. Send sample and quote lowest cash price.
WALTER S. POWDER,
175 E. Walnut St., Indianapolis, Ind.

FOR SALE.—One keg of No. 1 fancy clover honey; net weight, 111 lbs. \$10.00 buys it delivered on cars at Alamo. Address O. H. TOWNSEND,
Alamo, Kal. Co., Mich.

WANTED.—White comb and extracted honey; state price, package, etc. B. WALKER, 1774b
Capac, Mich., or Prairie du Chien, Wis.

FOR SALE.—Choice honey in sections, cans, and C. pails. Send for price list to OLIVER FOSTER, 12-14db, Mt. Vernon, Ia.

WANTED.—Southern honey. Will pay 5½¢ cash on arrival for good Southern honey.

22-23-24-1d CHAS. F. MUTH & SON,
Cincinnati, O.

WANTED. One or two thousands pounds of nice comb honey. Write giving amount on hand and price wanted. A. D. ELLINGWOOD, Berlin, N. H. 17fdb

FOR SALE.—50,000 lbs. of extra fine sage honey in 60 lb. tin cans. Also two carloads of light amber honey, for sale at 6¢ per lb., f. o. b.
L. E. MERCER & SONS, Ventura, Ventura Co., Cal.

WANTED.

I want to purchase at once, a large lot of

Light - Colored Combs of Honey

IN SIMPLICITY FRAMES.

Must be built upon wired foundation. Each frame, with honey, to weigh not less than three pounds. Correspondence solicited.

GEO. D. POWELL,

81 & 83 Third St., Brooklyn, N. Y.

MANUM AT HOME.

THIN OR THICK TOP - FRAMES IN VERMONT:
THE PROSPECTS FOR ANOTHER SEASON.

"Walk in, Charles. You are just the chap I want to see. I have been wishing some one would come in to chat with me. I have not had a good talk on bees since Mr. Root was here. I wish you had been here that day. You would have been interested in his talk on wide-thick top-bars and closed-end frames. Why, he had, as it were, every pocket stuffed full of wide end-bars, and a bundle of wide-deep top-bars under each arm, which he had collected while journeying through the State of New York; and, judging by the way he clung to them, I concluded he intended to take them all home with him."

"Well, how came he to become so greatly interested in so much surplus lumber?" asks Charles.

"Well, you know there has been much said in GLEANINGS of late on this subject, very many claiming that deep top-bars are a sure preventive of burr-combs; and many of the advocates of "deep top-bars" have attempted to show by their well-written articles that they are a success, and our young editor has caught the fever, and has got it bad. How long a run he will have, depends altogether upon what kind of remedies he takes, and in how large doses."

"I have never used top-bars any thicker than $\frac{3}{8}$," says Charles, "and I can hardly see the need of their being any thicker, unless it may be to prevent sagging; but I have no trouble with mine sagging; and surely with $\frac{1}{8}$ -thick bars there is $\frac{1}{8}$ of an inch to each frame of lost room; and, besides, there is just so much more space from the brood to the sections, that the bees have to travel over, to say nothing of the extra expense in lumber and work. Now, Manum, after talking with Ernest and reading the different articles on the subject,

what is your opinion as to the advantage the thick top-bars have over the thin, or $\frac{3}{8}$ bars? Do you think they will entirely prevent burr or brace combs being built?"

"Well, Charles, I will say to you just as I did to Ernest, that I have never used thicker top-bars than $\frac{3}{8}$ (mine now are all $\frac{3}{8}$), hence I do not consider myself prepared to decide, much less to advise. But I have had some experience with various kinds of hives and bees in different locations and in varied seasons, and I have pretty much come to the conclusion that the cause of the building of burr and brace combs is traceable to the strain of bees and the management or attention given the bees during any honey-flow, but more especially a late flow of honey. Of course, an improper space between the top of the frame and the bottom of the honey-board or bottom of sections, as well as the improper spacing of combs, has much to do, I believe, with burr-combs. But my experience of last fall, with a late flow of honey, leads me to believe that the one great cause of so much cry over burr-combs is due to a late flow of honey, which stimulates the bee instinct to fill up every vacant place or crevice at the approach of cold weather; hence these brace and burr combs are built to keep every thing secure and in a rigid position. This late flow, coming, as it does in most localities, after the surplus receptacles are removed, and being, as a matter of course, somewhat cramped for room, they have the very best of opportunity to exercise their bee-instinct to hedge in, much as we Northerners do for the winter, during our Indian summer. This fact we had the best of opportunity to observe last fall; for, you will remember, quite a number of my hives, as well as your own, were pretty well stuck up with burr-combs, especially the strong colonies that were full of honey. Therefore I am of the opinion that deep top-bars will not prevent the building of burr-combs during a good late flow of honey, or during any flow of honey when there is no other place to store it than in the brood-

chamber. However, there are very many extensive bee-keepers who use and recommend them, as well as closed-end frames. Notwithstanding that, as yet I do not feel the need of adopting them. They may be very essential in some localities, for surely some of our brightest lights say they are a success. I am, therefore, of the opinion that we Vermonters do not know it all yet. But, Charles, I can not help believing there is a little too much stress put upon the superiority of thick top-bars over thin ones."

"Have you got your bees all fed up for the winter?" asks Charles.

"Yes, all fed and packed, and my bee-work is done for this season. By reducing my number of colonies to a much less number than I have had for a number of years, I was able to feed them up to 25 pounds each, with only 14 barrels of sugar."

"Why! I thought you always fed up to 30 pounds," says Charles.

"Yes, I have usually; but, you see, when I came to examine my purse I found it rather thin. So I concluded to risk them with 25 pounds. That will winter them, and I can feed them in May, should they get nothing from soft maples and willows."

"What is the prospect for another year, judging from the present outlook?"

"Well, Charles, I never felt more hopeful in my life than I do this fall. Every thing, to me, looks very promising. Surely clover never looked better at this season of the year than it does this fall; and next year, being our full basswood year, it does seem to me that we ought to get another boom; and, with this hope uppermost in my mind, I am going to prepare for it this winter, in order to be ready for whatever nature may have in store for me. I feel so confident that we are to have an extra good honey crop next year that I am going to prepare and have in readiness 128 sections to each colony that I now have; that will be eight clamps, of 16 sections each, to the colony."

"Well, surely, Manum, you are counting on a large crop, sure. I think 100 sections to the colony would be enough."

"Yes, Charles, I am; and perhaps I am making too extensive preparations; but I believe it is well to be ready, and to get ready during the long winter, so as not to be obliged to sit up hot summer nights, when I am very tired, to prepare sections to meet the demands of a rush in the honey-flow. Be ye ready is the word."

Bristol, Vt., Nov., 1890. A. E. MANUM.

I should have been very glad to have met your friend Charles, but perhaps we can talk it over yet. I think I can explain our apparent differences. You Vermonters, or, at least, those bee-keepers round about you, use the Manum frame, the size of which is very nearly the crosswise Langstroth. Your top-bar is only about two-thirds the length of the top-bar on the Langstroth frame; hence I am not surprised that you and your friend should not be troubled with sagging of $\frac{3}{8}$ bars, when those of us using the Langstroth frame are. Dr. Miller, whom I have just visited, opened up a number of colonies for me. He has used exclusively, for years, top-bars $\frac{3}{8}$ inch thick; but you could scarcely find in his apiary a bar of that thickness that had not sagged more or less, and I think you will find about that state of affairs in most apiaries using the thin bars of Langstroth length, where the same is not supported by di-

agonal wires and a tin bar; and the majority of apiarists, if I am correctly informed, do not so brace their top-bars. To sum it up, your top-bar $\frac{3}{8}$ would be about equivalent to a Langstroth top-bar of $\frac{3}{8}$; and it begins to look as if $\frac{3}{8}$ inch thick, and a full inch wide, would answer.

There is no doubt that the strain of bees has something to do in the matter of building much or little burr-comb. We have observed the same thing in our own apiaries. The point is, we want to make *all* strains of bees quit that unnecessary work.

When I visited your place I was surprised that you did not have burr-combs on your top-bars, to the extent we do. It is quite likely that your bees do not build as many as the average Italians; but I think you told me that you used only $\frac{1}{4}$ -inch bee-space, and your bars were an inch wide. Either one of these factors alone, outside of any disposition on the part of the bees, would tend very materially to diminish the building of brace-combs.

Next time I visit you, friend M., I hope your friend Charles will be present. Possibly I am now over-enthusiastic, and the next time I visit you I may have changed my views a little. I don't wish to ever get to that point where I *won't* be set right if wrong. E. R.

THE RIGHT BEE-SPACE.

THE BURR-COMB QUESTION, AND THE SPACING OF FRAMES.

Referring to the burr-comb question, I do not understand why Mr. Elwood's inch-wide by $\frac{3}{8}$ -thick top-bars with distances "fixed" with closed end-bars are any better than the same bars would be with distances fixed with a spacing-stick or measure. The secret, probably, is in the inch-wide top-bars with $\frac{3}{8}$ spacing and no sagging. This fall my bees seem to be shoving up the quilts, and building brace-combs between the quilts and brood-frames, leaving little passageways for themselves. Measuring the ones just the right height for the bees, I find them an exact $\frac{3}{16}$. From this I should conclude that the right distance between the brood-combs and supers is $\frac{3}{16}$ of an inch. The distance between the top-bars should be twice $\frac{3}{16}$, or $\frac{3}{8}$, the old Langstroth bee-space. Then with the $1\frac{1}{8}$ spacing, give us the 1-inch top-bar, and we have the $\frac{3}{8}$ space between the bars.

The sections in T supers can be held square with an extra set of T tins between the tops of the sections, the same as the bottom. The combined crate has given me the best satisfaction so far for a super, on account of the bars with insets to suit the sections. I presume the section-holders would do as well, although I have not tried them yet.

EGGS IN THE MANUFACTURE OF ROYAL JELLY.

Two or three experiments this summer incline me to the idea that bees use eggs in the manufacture of royal jelly for queen-cells. I have not yet been able to prove or disprove the idea. I wish somebody with more time would try it.

A drone is a son of his mother, but not of his father. In fact, he has no father. Although he has no father, yet he is a grandson of his

grandfather. He is only a half-brother to his mother's daughters. According to the above theory, it is important that we know the good qualities of the drone's grandparents when we wish to rear a special set of drones.

A queen lays a while, then takes a rest. I suppose she goes to "clucking," like an old hen. When she gets to "clucking," then she swarms like honey is coming in plentifully. Some queens, like old hens, "cluck" more than others.

Bonney, Pa., Oct. 14. PHILLO S. DILWORTH.

It doesn't matter how you fix frames, as far as the burr-comb question is concerned. The point is, *convenience* of the one or the other method. I feel very sure that frames fastened with separate and removable spacing-sticks can not be handled as rapidly as the Hoffman or closed-end frames. A visit to one of the large apiaries using either one of these frames will show you the difference.

I believe you are pretty nearly right in regard to bee-space; though $\frac{3}{16}$ is a little *too* small, a quarter-inch, a little scant, if any thing, is about right.

Bees do assuredly make way with eggs at times, but it remains to be proven whether they use them for food. This has been before advanced. Cheshire says the royal jelly is a secretion from glands in the head of the nurse-bees.

NOTES OF THE SEASON.

SOME VERY PRACTICAL SUGGESTIONS FROM H. R. BOARDMAN.

We have had another season of failure in the honey crop, but it has not been without its lessons of valuable instruction. This may compensate in a small degree, although it will not help us much in buying bread and butter this year. "What are we to do under such discouraging circumstances of continued failure?" I have been frequently asked. I can answer only for myself. I have already begun, with renewed energy and determination, the most careful preparations for the next season, determined to do my part more thoroughly and faithfully than it has been done, and I have yet confidence in this kind of work, even in a poor season. So long as the almost universal report shows that the bees were not in the condition they ought to have been at the beginning of the honey season, it is quite evident that some share of the responsibility for short crops rests with the bee-keeper, and is not chargeable wholly to poor seasons. Then the results of a colony here and there that had sufficient stores to keep up brood-rearing to the beginning of the honey harvest, are suggestive of the remedy. Yet I might as well admit, that, with all the energy and care we may throw into the business, the future of bee-keeping has no very flattering outlook in this part of the country. But even with all that seems discouraging, when I look about me and see the sharp competition for bread and butter in every department of life, it becomes evident to me that I *could* do no better at any thing else I might undertake, and perhaps I *should* not do as well.

BURR-COMBS.

The discussion at the Cleveland convention, upon thick top-bars as a means of preventing burr-combs in the bee-space above them, set me to thinking upon the subject, and especially the question asked by some one present—"Why do

bees build burr-combs?" and I have set about trying to discover some reasonable answer to the question. I find, in looking over the back numbers of the bee-journal, that favorable reports accompanied close spacing, and that unfavorable reports accompanied wide spacing. I went into an examination of my hives and supers that had been used, of which I had an abundant supply, and, almost without exception, these showed the burr-combs on the tops of the frames to be only a continuation of the combs built from below up through the bee-space by shallow or rudimentary cells built on the sides of the top-bars, and thus contracting the bee-space between the top-bars to that of the combs below. The same thing occurs at the sides of the frames, and burr-combs are built in the same manner between the side-bars and the sides of the hive whenever the hive becomes crowded, as I had ample opportunity of observing on some old $\frac{3}{4}$ -inch side-bars. The break-joint honey-board placed between the brood and surplus chambers intercepts these combs that are built upward from the edges of the top-bars, but does not prevent them—simply catches them in a bee-space provided for the purpose.

I said, if the frames were closely spaced it would at least prevent the bees from building up between the top-bars for lack of room, and deprive them of these starters from which to build these objectionable combs in the space above the frames. I accordingly arranged about 25 colonies, selected at random in four different apiaries, by spacing nine frames in a hive where I had used but 8. The hive is 12 inches inside. This would make the distance of the frames from center to center a little less than $1\frac{1}{2}$ inches. I do not undertake to show this to be just the right distance for spacing, but it approximates it, and answers the purpose of my experiment. In old colonies thus treated, the combs were trimmed down. In new swarms, natural combs were built only on starters. Most of the frames used were $\frac{3}{4}$ wide by $\frac{3}{8}$ thick; a few were an inch wide. I was agreeably surprised at the results of the experiment, as showing the advantages and benefits of close spacing of the frames. I will give the results as they appear to me from the experiment.

ADVANTAGES OF CLOSE SPACING.

1. It prevents, or very much reduces, the tendency to build burr-combs above the frames. In some colonies, tested where a close bee-space was preserved above the top-bars, as well as between them, *no burr-combs* were built at all; but where a wide space was allowed above the frames, more or less combs were built.

2. It secures the combs built of uniform thickness, smooth and even with the frames; consequently,

3. It makes them available for brood to their extreme edges.

4. It increases the capacity of the hive without enlarging it, in my case, one comb.

5. While the capacity of the hive is increased for brood, it is diminished for bees, and therefore crowds them out into the surplus apartment; and for the same reason,

6. It enables the bees to cover and protect more comb surface, and consequently to rear more brood and to build up faster.

7. Where natural comb is built it prevents the building of drone comb to a great extent. It will be seen that, in close spacing, the building of natural comb has some decided advantages, as the bees adjust or space their comb-centers throughout all their slightest undulations, in a more perfect manner than it is possible to do it by any artificial means. The great importance of this is apparent.

One important test yet remains—that of

wintering—which I shall make and watch with care during the coming winter.

THICK TOP-BARS.

I am not satisfied that thick top-bars alone, without close spacing, will have much effect in preventing burr-combs, although the difficulty of building the combs up between thick top-bars is increased in proportion to their thickness. Therefore thick top-bars and close spacing may be more efficient in producing the desired result than those of medium thickness, say $\frac{3}{8}$ inch. But before lumbering up all my hives with such bungling fixtures I should want to know beyond any question that some very decided advantage was to be gained by it. My frames are $\frac{3}{8}$ full all around. I was quite certain that I gained some advantages in having them so heavy. I have been told many times that they were too heavy—too much waste wood in the hive; that the extra thickness made them clumsy and awkward. But it is some relief now to find out that these frames which I have used all of these years were *not* too thick, but they prove now to be much further out of the way by being too thin. The Irishman who said, "Of all the axframes give me the middle one," quoted a very safe maxim. My advice would be, in introducing these extra-thick top-bars, "Go slow in making *all* such changes until the facts have been established by the most careful experiments." These any one can make in a small way without wasting very much hard-earned money.

FIXED FRAMES.

In close spacing, uniformity and accuracy become very important. There is just room enough, and none to spare, for each comb; and the result of crowding one comb out of its place in the least would result in an infringement upon the one next to it, shortening the cells, and making it unfit for brood. We might, with much care, space the frames so they would approximate uniformity at the top. But please tip up your hive, and look at the bottom of the frames if you really care to detect the errors of spacing in hanging frames. I made a spacer this season for my inexperienced help, which did the work very well and quickly; but when I came to examine the combs at the bottom of the hive afterward, I almost became discouraged with hanging frames. Close spacing, I am sure, would necessitate the use of some style of fixed frames which have some good features to recommend them.

I have moved bees quite extensively for several years, to catch the local honey-flow. In doing this, the frames all have to be examined and secured. During this work this season I assure you that many times the convenience of fixed frames was forcibly suggested to me.

BEE-ESCAPES.

Who doubts their being practical? Certainly no one who has had much experience with the simplest form of wire-cone escape for getting bees out of the supers, and knows how to use them. I use them entirely for removing all of my surplus, and have used them for several years. I know better how to use them than I did a few years ago, therefore with me they have become more practical. I use the one illustrated and described by me in GLEANINGS about two years ago. I doubt whether any improvement of importance has been made upon it since. It is so simple that any one can make it, and no one would think of taking off surplus without, after learning its value. I use it now, substantially as described by Mr. Reese.

JAPANESE BUCKWHEAT.

A piece of ground sown with Japanese and the old black variety of buckwheat this season,

side by side, shows the old variety to be much superior for bees, as it blooms fuller and remains longer in bloom.

MOVING BEES.

I read the very thrilling experience of friend Baldensperger, in moving bees on camels, with intense interest. It brings to the surface some vivid recollections of a similar kind. Although I never moved bees on camels, friend B. can count on my sympathies. I have some methods that are new and novel in this work, so far as I know.

H. R. BOARDMAN.

East Townsend, O., Sept. 20, 1890.

I have read your article with general interest. Perhaps bee-keepers have been depending too much on the season rather than on themselves.

You are so habitually careful in your observations and deductions, that your notes on the subjects touched upon are doubly valuable. You are drifting in the right direction; viz., fixed distances and dispensing with burr-combs. As to the latter, close and *exact* spacing, with an increase in thickness of the ordinary bars, are important. As to fixed distances, I believe that you and a good many others would use fixed distances *if* you could be convinced that they would not retard your present rate of frame manipulations. I may be over-sanguine, but I feel quite sure that *time*, and not a very long time either, will do it. Your first experience with them won't be favorable, but when you learn the "hang" of them you will be pleased.

About the bee-escape: I am also sanguine enough to believe that its real value is not sufficiently recognized. Mr. Manum uses it very much as you do, and he can take off a whole crop of honey from an apiary in three hours.

E. R.

SPRING DWINDLING.

MRS. HARRISON SAYS IT IS NOT AS BAD IN THE CELLAR.

Womanlike, I want to put in a word in reference to bees, that are wintered in the cellar, dwindling more in the spring than those that remain out of doors. My experience is, that they do not dwindle as much. Where bees are wintered on the principle of the good old golden rule, "Do unto others as you would that they should do to you," whether men, horses, or bees, their vitality will not be injured by cellar wintering. When our bees were removed from the cellar it was thoroughly cleansed and whitewashed. The brick floor was scrubbed, and the dirty water was not allowed to soak away, but wiped up and carried out, and fresh water used. If there were any discharges from the bees on the surface not whitewashed, it was scrubbed off. Ever since, the fresh air has been circulating through the sub-earth ventilator and open window above. The cellar is built in dry sandy soil, and there is no dampness—if any thing, it is too dry.

When the bees are carried into this clean, healthy cellar, the ventilation is kept to suit conditions, and dead bees are not allowed to accumulate and decay, but are swept up and carried out. If the bees get noisy toward spring I infer that they are thirsty, and either wet cloths are put at their entrance, or snow-

balls, and they quiet down. We winter our bees as an Englishman takes his beer—"alf and 'alf." One spring, the bees out of doors carried in large loads of pale yellow pollen the 2d and 3d of March; and it seemed too bad that the bees in the cellar could not have any of this fresh new bread. The spring proved to be a cold, inclement one, and bees could not fly for six weeks; and when the bees were removed from the cellar they were the strongest. We usually sell a few colonies every spring, and say to our customers, "Pick out your bees," and invariably they have chosen bees that wintered in the cellar.

BEET SUGAR, AND WHAT MR. THOS. WILLIAM COWAN SAYS OF IT.

Some one remarked, at the late convention, that white sugar is white sugar, whether made from sugar-cane, beets, or sorghum. It may be so, but I very much doubt it. Diamonds and charcoal are both carbon; but, are they the same? British bee-keepers have had experience with beet sugar; and if sugar is sugar, why does Mr. Cowan say that beet sugar will not do for winter feeding, but cane sugar must be used? I never knew of his having a sugar-cane plantation. MRS. L. HARRISON.

Peoria, Ill., Nov. 12.

My good friend Mrs. H., your reasoning is good in regard to cellar wintering, and I hope practice corroborates it; but with our open winters south of Lake Erie, as we are, I am not sure that horses and cattle would be in greater vigor kept in basement stables, than if they had the run of the open air during mild weather; and in our localities bees certainly seem to have more vigor when they have a flight at least every month in the year.—I feel a little sorry that this matter of beet sugar being inferior has come into print at all, for it is surely a great big blunder. Before answering you I tried to hunt up a copy of a government report, telling of the progress made by the beet-sugar industry, and stating that the sugar consumed in the United States was now over 60 per cent made from beets. If the sugar from the beet industry differed in any respect whatsoever from that made from cane (of course I refer to white sugar), our government surely would have mentioned it. Will Prof. Cook please corroborate what I say?

CONTROLLING INCREASE.

THREE METHODS.

Two years ago, when the honey-season proved such a failure, I had my bees at a distance from home; and, deciding to bring them back in the fall, for two reasons I aimed to keep down increase within certain limits: viz., to have the fewer to team, and the fewer to put into winter quarters; as the capacity of my prospective cellar, which was not yet excavated, was going to be very limited. I was then working with the Jones single-story hive principally; and as, in the locality there was just enough honey came in during the season to provide liberally for brood-rearing without occupying any room for storing, the queen had full sway of the hives, and the bees multiplied "prodigiously," as the Antiquary would have said.

I had strong compunctions against controlling the increase by pinching the heads of good queens; and so, when I had all the bees desired, I resorted to the plan of hiving swarms back into the old hive without a queen, having picked up the queen, which is always clipped, and placed her with two or three combs and adhering bees, in an empty hive, which was placed at an angle alongside the other, and finally doubled up with it a little later on, when the swarming season was over. This was done when I had made all the addition to stock wanted, and when the honey-season was so well advanced that I had ceased to look for any more surplus honey.

All I had taken or did finally take that season, amounted to 400 lbs. from some 60 hives, spring count. I considered this way of preventing increase only a make-shift plan, of course; but the way I have managed the matter this past season has, I believe, a good deal more to commend it. I am still a learner—a novice you might say—but that tough old schoolmaster, Experience, has been knocking some things gradually into my head; and among them is this: That, with a two-story hive, increase can be controlled to a much better advantage, and, I believe, the prospects for surplus honey improved. I don't like the idea of resorting to the old barbarous habit of sulphuring the surplus bees at the end of the season, as some suggest. To me it seems at least unscientific, if not cruel, and I think there is surely a better way.

This season I was changing my frame from 12½ inches deep, 10¼ wide, to 10¼ deep, 12½ wide, and the transferring was attended to right through the honey-flow, just as I could best crowd it in, and this reduced me to the following methods, which I found to work admirably:

1. As stocks got strong enough I added an empty super with, say, half a complement of frames of the new style, filled either with foundation or transferred comb, and the number of combs was added to gradually till the full quantity was made out. Two division-boards, of course, were used meantime. In only about one case in thirteen where I did this did I have a swarm, though the bees were remarkably strong. Our honey-season was a very poor one, however, and the queens, having so much scope for the exercise of their function, may on this account have been satisfied to stay at home.

The stocks in these hives were, at the end of the season, when breeding was over, shaken out of the lower story, which was removed, the bees being left to winter on the new-style frame of the upper story, which now takes the place of the original hive. The lower-story combs were then freed for extracting and transferring for next season. Part of the yard was attended to this way, and the other part as follows:

2. When a swarm would issue it was hived on the old stand on foundation, in the new-style hive, and the old hive placed on top.

When the brood had well hatched out, the queen-cells having been removed at the right time, the combs were extracted and transferred, then placed back on the swarm, in a super without a bottom-board, the quilt on the under hive being the only thing separating the two lots of bees. The upper-story entrance was left open for a few days.

The day after extracting and transferring frames, the separating quilt was pulled back an inch from the front, to let bees gradually mingle, and next day they might be removed altogether, and the upper entrance closed at nightfall with a strip. The bees would mingle

in the most harmonious way, and the upper story be made the receptacle for all surplus.

By this plan it was optional whether to leave the old queen in the lower story or do away with her and let her duties be taken up by a young one coming forward alone; but as I was satisfied with most of the queens already there, I carried on my rearing of such young queens as I wanted, elsewhere.

By following these methods I avoided undesirable increase, and assured good strong colonies for the fall flow, and for winter quarters, and had no call to resort to the inhuman practice of brimstoning. Next year I purpose to use a honey-board to confine the queen below.

Galt, Ont., Can., Nov. 7. R. W. McDONNELL.

The first method of preventing increase—that of placing the swarm in a hive at an angle to the old one is essentially the one advocated by Mr. Heddon several years ago. It does not always work. The two other plans are modifications of Mr. Heddon's plan of transferring. It is pretty generally conceded, that, if the queen is given unlimited breeding room above and below, in extracting, the bees are not apt to swarm.

A PLEA FOR OUR BRETHREN OF THE MEDICAL PROFESSION.

BY N. A. HUNT, AUTHOR OF TOBACCO MANUAL, ETC.

Dear Friend Root:—I was rather sorry to see the article headed "Medical Facts," in *GLEANINGS* for Nov. 1. Its influence, I fear, must be bad on many. We all know, of course, that not a few who practice medicine, even some who graduated at our best medical schools, for various reasons are not fitted to practice medicine.

Up to the time of the late war, and for some years after it, great numbers, especially in the West, took up the practice without any special preparation. Some I knew, who, having failed in other business, got a pair of saddle-bags and started out, thinking to make themselves physicians by practice. Happily that state of things has well nigh come to an end. When I went to Southern Illinois, in 1844, having myself had a medical education, I naturally took much interest in the success of physicians, and observed their modes of treatment. My ministerial duties gave me a good opportunity to do so. On the south of me the only regularly educated physician lived at Golconda, 50 miles distant; on the north I could reach a regularly educated physician by going 30 miles. But physicians were plentiful, nevertheless.

I have, for more than 50 years, been familiarly acquainted with physicians—Allopathics, Thompsonians, Eclectics, Homeopathics, and I have also, in an especial manner, tried to acquaint myself with the cold, tepid, and hot water system. As in religion (as you know, Bro. Root), experience is worth more than theory; so with me. Experience and observation in medicine have vastly more weight than mere theories.

Now for experience and observation, as it has come under my eye, in medicine. When I was about a dozen years old, one afternoon I went chestnutting and ate too freely of the nuts. Early in the night I began to vomit and purge. The doctor was sent for, but it was daylight before he reached me—pulse scarcely discernible, and nearly all sensibility gone. By remedies in his possession he restored me.

I have eight children living. Nearly all of

them, at some time in their lives, have been in critical conditions—something must be done, and done immediately. My youngest son, a few years ago, in spite of all my remedies and all the skill that I possessed, was fast sinking. I sent for another physician. He came, and took a course that I had not thought of—indeed, was ignorant of. It turned the scale, and my son recovered. During the last few months one of my daughters was thought to be lying at death's door. She was first taken with the grippe, then suffered a long run of typhoid fever, and, lastly, tumors formed internally. We had three physicians, of note, in the last extremity. Five surgical operations were performed on the tumors, and for two weeks nothing was taken by the mouth but ice-water; all nourishment and medicines were administered by enema. She is now well.

One fact I wish here to relate, not that it has any thing to do with the question I am discussing, but it should have weight in the discussion of the liquor and tobacco questions. After my daughter was fairly convalescent, we felt that the opiates, that had been used to a large extent, must be stopped. In the night I heard her in great distress, as it seemed. My wife got up, went to the sick-room, and stood by the bedside, where stood the trained nurse and one of my sons. She was crying and pleading bitterly for the morphine—an example of the drunkard, tobacco-user, and opium-eater. My son was resolute, and, in spite of the cries of his sister, whom he loved dearly, and the wishes of the nurse, he said, "No! it's time to stop the anodynes."

Some years ago a next-door neighbor was taken down with pneumonia, and wanted me to treat him. As I had carried him through a similar attack a year or two before, I consented. By the third or fourth day I saw that my remedies did not reach the case. I advised the family to send to the county-seat, where lived an eminent physician. He came, and, in kind, administered the same remedies that I had, but in much larger doses. The man recovered. It requires an accurate estimate of remaining vital forces to know when it is best to give double doses. I am sure I have witnessed wonderful success, in many instances, by increasing the dose double and treble the ordinary prescribed amount. But great skill is required in doing it.

About twenty years ago, on a visit to the East, I called to see a brother in Keene, N. H. When I got there he was unwell, and continued to get worse. On the third day after my arrival, and when I had calculated to start on, I felt that something more ought to be done than the young physician who was attending him was doing, and asked permission of the family to try to find an older physician in the city, and one of more experience. Such a one I found, and on the following day I felt it safe to pursue my journey. When I returned, two weeks later, my brother was up, and able to attend to business. For more than fifty years I have recognized not only the difference between the different schools of physicians, but the different treatment of physicians of the same school. Instances lie before me, in my mind, almost as thick as the manna did, six days out of seven, for the children of Israel to pick up as their daily food. The only question is, which to select from the common mass, to give a correct idea of what the practice of medicine should be, such as can be understood by the common reader. Leaving specific cases, we will turn to specific diseases.

Diseases change in form as they occur at different times, and under different circumstances. Scarletina passes about, sometimes proving fatal in very many instances; at other times it is no more fatal than the measles ordinarily is

So with yellow fever, diphtheria, and, indeed, with most other epidemic diseases. The last time yellow fever appeared in the South, taking Jacksonville, Florida, as an example, only one in twelve cases proved fatal. It used to be said, when I was a boy, that in ordinary fevers, such as they then had in New England, that five out of six would recover, with good nursing, without medicine. I lived about 30 years where malarial fever prevailed in various forms, from fever and ague to continued bilious-typoid. Our sheet-anchor remedies were some preparation of mercury and quinine. Four years ago I visited again the region of malaria, Illinois and Missouri, the southern part of both States, and, contrary to my expectation, I was taken down with malarial fever, identically the same that I had had so often 30 years before. The old remedies were used, blue-mass and quinine.

Before we quite dismiss the subject, whether physicians have a needed place in society, I want to call attention to surgery. Surgery belongs to the physician. None but a physician who understands anatomy, *materia medica*, and the vital forces of the human system, should use the "knife." In surgery, many valuable discoveries have been made during the present century. What middle-aged man ever heard of operating on ovarian tumor in his boyhood? A few years ago a physician started from Philadelphia, and in his trip to Minnesota and back he performed *ten* such operations. I happened to be acquainted with one of the ten. In all, I know three whose lives have been saved by removing such tumors. One of the three has been operated on three times for the same malady. I knew a girl thirty years ago who had had a large hole eaten through her cheek by the reckless use of calomel, as they said. The girl, as by instinct, kept her tongue in the hole (no doubt it felt better stopped than open). She was a sight to behold. A year or two ago I saw her again, and the cheek had no hole in it. She was a fine-looking lady. A surgeon had cut a piece of flesh from the arm, and caused it to grow into the cheek. Of course, the arm was fastened up to the cheek, and the flesh of the arm was not entirely discovered till its adhesion to the cheek was secured. Who will undervalue such surgical skill?

Once, the patient in a surgical operation had to endure all the pain that the nervous system could inflict: now, we have found out how to suspend the feeling of the whole body, or a part of the body, for a time, and we can cut or manipulate at will, with little or no distressing pain to the patient while we are doing it. Is any thing gained to the human family by these late discoveries in medicine and surgery?

Then in regard to the compounding of medicines—how crude our medicines were sixty years ago, compared with what they are now! Now a physician can carry in his vest-pocket, in efficacy, what would have taken saddle-bags to carry when I was a boy. I know not where to stop exalting the medical profession, when in suitable hands, and the better part of man, the spiritual part, is enlisted in the work. Were I a young man, with the views I now have of the relation of God to man, and the correlative duties of man to God, I can't see how I could better follow the footsteps of my Redeemer than by doing what I could for my fellow-man in this life—when sick, restoring him to health; when mangled and bleeding, binding up his wounds, and, in so doing, I could more effectually minister to the spirit, to fit it for the *other* state of existence.

In concluding this article I wish to say that no small part of a physician's duty is to in-

struct the people while they are in health, or comparatively so. An *ounce* of preventives is often worth a pound of cure. Eat and drink moderately such things as ought to be eaten and drank. Such things as, in their nature, are not calculated to sustain and build up the system, let alone, intoxicants and narcotics are of the latter class. If used as medicines, when the disease is subdued, stop the remedies. There is not an intelligent physician in the land, but will tell you that the use of liquor or tobacco tends to unnerve the system, and makes it less able to resist disease, and less capable of throwing off disease when it has once invaded the system.

N. A. HUNT.

Mapleton, Minn., Nov. 12.

Friend H., GLEANINGS did not mean to reflect by any means on the regular practicing physician. You are right in saying, however, that it requires wisdom and judgment in deciding *what* physician to employ when there are a great many. It is sometimes said, that "doctors disagree." May be some of you have heard the expression before. Well, is it not true that doctors are coming more into harmony than they have been? I confess it gives one's faith a severe shock when he consults different physicians, and they all contradict each other. In our town it is getting to be quite customary for physicians as well as ministers to counsel together; and it seems to me as if it gave us a glimpse of the "good time coming." Why shouldn't all the physicians of a small town, say like our own, unite together in giving counsel when the life of a beloved citizen is in great danger? By all means, let us have faith in the neighbors round about us. Of course, that does not mean the traveling ones.

RAMBLE NO. 33.

LAKE GEORGE.

Who can alight on as happy a shore
All the world o'er, all the world o'er?
—TENNYSON.

The peculiar charms of Lake George are found in several points, among which are beautiful scenery, clear and pure waters, and bracing air. The weary toiler in some rut of life's drudgery, for a brief season dwells upon this happy shore, and soon forgets the ache and the pain, exchanging them for the elastic step and the joyous laugh that throws dull care to the winds.

Every one who participated in the bee-keepers' camp at Lake George in August will attest to the happy time there enjoyed. The Rambler tried to be the first on the ground, but Nig was not so fleet of foot as the little sail boat of Larabee Bros., favored by a booming wind, and they distanced us by about an hour. We were, moreover, loaded with a variety of fishing-tackle that would puzzle the brains of Ike Walton himself. Brodie Higley, our 17-year-old companion, and the youngest bee-keeper of the camp, had borrowed all the fishing-tackle in two neighborhoods, and had every thing from a fiddle-string to a clothes-line, and was bound to clean out Lake George. Bros. Lockhart welcomed us, and we had a cordial hand-shake all around; and, pitching our tents, our camp began to assume quite a business air. We retired early, after the fatigues of the day; and

the waves lapping monotonously on the dock, a bull-frog melodiously blowing on his mouth-organ, and Brodie's nasal music, soon lulled the Rambler to a sweet repose.

The next day we perfected our camp, and appointed ourselves a reception committee of the whole, and received Mr. Barber, a bee-keeper who owns 40 colonies—save one. At evening we received our fisherman Brodie, who had industriously tried all of his fishing-tackle, and reported one minnow and three pickerel—save three pickerel.

The heavy clouds that had been skirmishing around all the afternoon finally got down to business, and the floods came. We all felt that something unusual was going to happen, and, sure enough, several Vermont ladies poured in upon us—Miss Douglass, Miss Wolcott, and Miss Andrews. After the excitement had subsided we all sought our respective lodgings.

The next day all nature was smiling. We donned our smiles also, and received Bro. E. R. Root, Mr. and Mrs. Knickerbocker, Messrs. John and Cyrus Andrews, and their natty little steamer; Miss Van Orden, Mrs. Fisher and son, Mr. Batchelor and friend. That evening was beguiled with song and story until the "wee sma' hours."

Quite a number of topics of national importance were discussed. Having an editor with us, editorial chirography was freely criticised. We were expressing our opinion of an Eastern editor's pen-tracks, when Brodie, who had been taking a private nap in the corner, shifted his position, and murmured, "Yes, it looks like pickerel tracks." We all smiled more or less audibly, and it was resolved that the Rambler go fishing on the morrow and teach his companion how to catch pickerel. It was also unanimously resolved that the type-writer is a blessing to bee-keepers.

At this point Bro. Larrabee took the floor, and declared war on England for opposing the McKinley tariff bill. He said Vermont could easily wipe out England. He had invented a bee bomb-shell that would scatter consternation wherever it fell. He had read about two or three bees breaking up a camp-meeting. A few Vermont swarms would rout a whole army; or we could take Cuba, or any other land. We were so impressed with the magnitude of this

ness we had some little discussion over the matter. Some one suggested that we allow time for his name to get to him, and call him ten minutes earlier. Another wished to abbreviate and call him Knick—no, that will degenerate into Old Knick. Say, we'll call him George—that's it! and it solved the difficulty—George was always prompt.

Bro. Root bade us farewell that morning, and set face toward Vermont. After the farewells had been spoken we turned our attention to fishing for pickerel, and came in, after a successful cruise in Dunham's Bay, with 19, the Rambler, with the largest, and we thereafter dined on pickerel. The Hawkeye in the hands of W. Larrabee caught us as we landed.

On Friday our Vermont friends all departed. Farewells were spoken; regrets and locks of hair exchanged; and, as a last kind act, we waved our bandanas. Breaking camp is always a pathetic scene to us. Somebody is sure to forget something, and come tearing back after it. One lady forgot her b—bu—button-hook, and it became necessary to say good-by all over again. A second good-by, said by one party on the run, and out of breath, never has the *eclat* of the first one.

BRODIE GOES IN SWIMMING.

After the final departure, Brodie and the Rambler finished the day with a fishing-trip—caught three pickerel; got stranded in a storm on Jacob's Rock; and, to make the final episode as interesting as possible, Brodie suddenly left me and went down to visit McGinty. But he was remembered by the Hawkeye and the

RAMBLER.

THE GREAT LOCUST OF FLORIDA.

LOCUSTS IN GENERAL.

The immense grasshopper, or locust, sent by E. J. Baird, Orlando, Fla., is a giant locust. It is a female, and actually measures over two inches in length. The wings are shorter than the abdomen, while the antennæ are very plainly jointed, and taper to the end. Beneath, the pro-sternal spine is very large. The color of this Jumbo locust is yellow, orange-yellow, and black. The tegmina, as the upper wings of grasshoppers are called, are striped with red. The under wings, which in all grasshoppers are the important organs of flight, are marked with red and bordered with black. These wings fold up as we fold up our paper fans. They are powerful as organs of flight, and, in the migratory locusts of the Orient and our Western States, often bear the insects hundreds of miles. It is well known that locusts are great eaters, and often destroy nearly all vegetation. The locusts of which we read in Scripture were longer than this one, but not so robust. We have the Syrian locusts in our museum. They are interesting, not only as the insects that destroyed Pharaoh's crops and brought famine in the olden times, and in later years, but as the diet which in part supported John the Baptist. Our Katie is at present a Sabbath-

WE DINED ON PICKEREL.

theme that we again sought our couches. The Rambler had a fitful slumber. Bro. Root was so impressed he arose at 4 o'clock and went out on the mountain-side and sat on a rock. All the rest were very somnolent until a late hour. The breakfast-call, however, brought all hands around except Bro. Knickerbocker. As Bro. K. is always prompt in his queen busi-

school teacher. She asked for these great insects a few Sundays ago, to show her class. She said they interested her pupils greatly.

It would be interesting to know whether this Florida locust is very destructive. If very numerous they must be, as it would take no little herbage to fill so corpulent an insect. Birds are great enemies to the locusts, and usually keep them from doing much harm. Other insects also feed on locusts; but occasionally they become so numerous even here that they are exceedingly destructive. Usually the oat crop is the greatest sufferer from these gormands. The locusts can be poisoned, but this is laborious; and we may well protect the birds, or, out west, set trees to attract the birds, and thus escape the raids of these terrible destroyers. The name of the insect is *Dictyophorus reticulatus*.

A STRANGE BEETLE.

Mr. H. W. Mitchell, Hawks Park, Fla., has sent me a strange beetle for which he wishes a name through GLEANINGS. The beetle is dark brown, very large, nearly $1\frac{1}{2}$ inches long, and an inch broad. It might well be called the "rhinoceros" beetle, as it has three long curved horns on its thorax. These make it look very savage. The real name is *Strategus antvius*, Fab. It belongs to the same family as the common June beetle, which it resembles slightly, only this is broader in proportion to its length. It has similar habits. That is the larva which has six legs, lives in the ground, and feeds on roots. The beetle does little if any harm. It eats foliage a little, but not seriously.

Agricultural College, Mich. A. J. Cook.

Friend C., we are not only interested in locusts, but I for one am very glad to know that Katie is now a Sunday-school teacher. As the years go swiftly by, we forget that these little ones are constantly growing old; and it is a glorious thought, too, when we can think that they are growing old in the service of Christ Jesus.

ANOTHER OUTSIDE WINTERING CASE.

TRIED FOR FOUR YEARS, AND A SUCCESS.

I see in your foot-notes, in reply to Rambler, page 743, where he mentions Mr. Wm. B. Stephens as wintering his bees outdoors, packed in outside cases. Now, I have been practicing the same plan for the last four winters, with all the success that could be desired. I now have 70 colonies packed on their summer stands, and I do not anticipate the loss of one per cent during the winter. My cases are made to admit a packing 4 inches thick on the bottom and on each side, while on the top it is 6 inches. I make them in two sections for convenience in packing and unpacking, and the bottom is made a trifle smaller than the inside of the case which rests over it its thickness, and rests on the corner-posts, which are $1\frac{1}{2} \times 1\frac{1}{2}$ inches. My hives are made with an entrance the whole length of the end-board; and in order to make the same free from the outside of the case to the inside of the hive I take a board 4 in. wide, and as long as the hive is wide (outside measure), and nail a piece 1 in. wide by $\frac{3}{4}$ in. thick, just far enough from each end and across the board, so that, by letting the ends project a little, they will slide into the entrance close up to the side boards, and hold it fast. These cross-sticks must be long enough to receive the alighting-board, which is to be nailed on the other side of the cross-sticks from the other board, so that

the edge of the first board furthest from the hive will be just opposite the edge of the alighting-board next to the hive. I nail my case-bottoms to pieces of scantlings, and my hive-bottoms to pieces of 2x4, which, when placed on the bottom of the case, leaves a space for packing, as above stated. Now cut a piece from the center of the front end of the bottom case, as long as your hive is wide, and as deep as the distance from the top of the cross-pieces to the entrance-board to the lower side of the case bottom, and set on the lower section, and pack it. Then put on the other section, and pack that, and you will, in my opinion, have the best security for bees that can be devised.

Lanesboro, Pa., Oct. 27, 1890. P. L. NORRIS.

The reason for proposing an outside wintering shell or case was to get something cheaper than a double-walled hive; but I fear, from the description of yours, it would cost as much or more than a double-walled chaff hive. We want something that will not cost over 35 cents at wholesale, and all in one piece. I have no doubt but that your case would winter the bees successfully. E. R.

ERNEST'S NOTES OF TRAVEL IN VERMONT.

AT J. E. CRANE'S, MIDDLEBURY, VT.

I took the steamer up the lake to Ticonderoga, a town of 4000 inhabitants, at the head of the lake. A short distance out is the celebrated old fort bearing that name. As I retired that night at the hotel I promised myself the pleasure of seeing at least the site and a part of the wall of that old historical spot. Next morning I took the train, and was told that the fort was on the right-hand side in plain sight. I thought that I should surely be able to pick it out when I got to it; but, lo and behold! the first thing I knew I was three or four miles beyond it, and had not seen it.

My next point was Middlebury, Vt., the home of a prominent and extensive bee-keeper, Mr. J. E. Crane. As I neared the place I began to notice the big hills that I had left back in York State, and over in the distance the Green Mountains. I alighted at the depot, and inquired my way to Mr. Crane's. When I had arrived almost there, a handsome residence was pointed out to me, with ample lawn and commodious barn and shop. I inquired at the house, but found Mr. Crane was out in the back yard, in his garden. Like some other bee-keepers, small fruits are one of his hobbies. He began to talk about the different varieties, assuming that I understood all about them; but I had to confess, that, despite all the opportunities I had had, I knew little or nothing about such things. He seemed a little surprised, but I told him that I did not dare to get much interested in any thing outside of bees; for if I did, I might lose interest in my real pursuit.

In the front part of the garden were a few hives. Most of his bees—500 or 600 colonies—were in out-apiaries. The hives were of the Manum type, although he was using the L. frame. He did not see but that he wintered his bees just as well as his friend and neighbor with a frame more nearly square. We repaired to the barn, wherein was his bee-shop and honey-storage room.

Our friend Mr. Crane has been rather more fortunate than most of his neighbors whom I visited. He obtained, I think, 11,000 lbs. of honey. The season had been a little better than with his friend Mr. Manum, only eight or nine miles distant.

Among the things in the shop that interested me particularly were the clamps, or honey-crates, for holding sections. There were also samples of the original thumb-screws that had been used for clamping up the sections some ten or twelve years ago. It seemed that Mr. Crane wanted some sort of arrangement to clamp up his sections; and I believe he suggested something in the nature of a screw. Mr. Manum, his appliance-maker and bee-keeping friend, soldered a brass thumb-plate to a common screw, and these they both used. But they, subsequently, used wooden screws, the same that Mr. Heddon has since adopted. But Mr. Crane has discarded them for a wedge. He thought it was more convenient, and did away with the unpleasant projections in the form of thumb-screws outside of the case.

HIVES WITH THE ENTRANCE THROUGH THE BOTTOM.

Among other things that interested me greatly was an old bottom-board. It had a square hole in the center, and an alighting-board under it. The bees, to enter the hive, pass under the bottom-board up through the aforesaid hole into the hive. Mr. Crane believed he was original in the use of such a bottom-entrance hive, he having devised this a great many years ago. There were many nice things about it; but, taking it all in all, he had discarded it for the ordinary entrance in front of the hive.

Perhaps I might remark, in passing, that Mr. Elwood, Mr. Manum, and Mr. Hetherington, use bottom entrances—that is, the bees pass directly *under* the hives. Mr. Elwood, when the bees are to be moved, closes the hole with a slide and the bees are shut in. For outdoor hives that are to be left on their summer stands

CRANE'S HONEY, READY FOR MARKET.

in double-walled hives, this sort of entrance is certainly a nice thing. It is quite impossible for the snow to bank up in any way so as to close it. For a single-walled cellar hive, the bees have only to be carried into the cellar, the slide withdrawn, and the bees have ample bottom ventilation. If I am correct, this is the way that Elwood, Hetherington, and L. C. Root give bottom ventilation in their cellars.

Another thing that interested me particularly was Mr. Crane's method of packing honey for market. He had a few thousand pounds already prepared for market. I photographed a pile of it standing in the barn, which I herewith present to you.

He puts all his honey in cartons, also neatly lettered. A certain number of cartons filled with honey just fill a case. They are not glassed, but the sides are left open, and the cartons are ample protection for the honey. The cases are made of beautiful white poplar, and are lettered by stencil in black and red, with a handsome monogram, and an old-fashioned straw bee-hive tastily arranged in the lettering. It is all carefully graded, and named according to the grade. The pile I photographed above was about the handsomest lot of honey for market I ever saw. I am sorry the print doesn't give it more justice. While I was admiring his honey, a little girl came out to the barn to see her papa. He seemed to be very proud of her, and well he might. When this little one came into his family he named her Theodora, from two Greek words, meaning "gift of God." I thought, "How nice it would be to have her sitting by two or three of those pretty crates of honey, out in the bright sunlight!" We arranged some crates, and by this time the boy came out. We stationed the two by the side of the cases, and with the Kodak I took two or three shots; but as it was near the end of the film it was not a good picture or else I should have been glad to introduce all our readers to little Theodora and her brother Philip, the latter named after Mr. Elwood.

We now went into the house, and I met Mrs. Crane. Into the parlor we repaired, and Mr. Crane said he would like to show me something he was interested in. He produced a box containing a large collection of stereoscopic slides, illustrating different phases of the temperance question, showing the effect of taxation, license, and prohibition. During his spare winter months he devotes his time to the cause of temperance, and lecturing on the subject. Perhaps some of our readers may know of him through the columns of other papers.

After dinner, Mr. Crane kindly offered to take me across the country to Mr. Manum's, who lives eight or nine miles away. We ascended some pretty big hills, and had some fine views of the surrounding country, and the fact seemed to impress me more than ever that a good bee-forage is generally found in mountainous or hilly countries. After a very pleasant drive and visit we reined up before Mr. Manum's house. You know the rest as given by Mr. Manum, recently. He was in his bee-shop, and, of course, the first thing I did was to get inside of it and look at all the fixings. "What is this? and what is that for? Oh! this is what you described in GLEANINGS. Ah! I see," and so on.

MANUM'S BEE-CANDY, ETC.

Mr. Manum has already told you that my stay was short, and so, of course, I put in the time about as fast as I could, asking questions after the manner of the above. There was his swarming-arrangement that he had described in GLEANINGS. He has a little frame for hatching queen-cells, the same as was described and illustrated on page 629 last year. He showed me a pan of his bee-candy. Why, it *would keep four years*, and still be soft, and good food for bees. I may remark in passing, that we are now experimenting with it, with the view of adopting it next year for mailing queens in the Benton cage. The trouble with the Good candy is, it is apt to get hard when it goes into a cold climate. We have had some lately that became as hard as a brick, and the bees actually starved to death, as was shown by inspection of the cages returned. Mr. Manum adds a very small quantity of *glycerine* to the sugar and honey to prevent this. To save you the trouble of referring to back numbers, I will give the formula:

Eight spoonfuls of coffee A sugar; one of wheat flour; one of glycerine; two of granulated honey. First mix the flour with the sugar, then add the glycerine and honey. Let it simmer on the stove until the sugar is dissolved, and then remove to cool.

MANUM'S CLAMP: THE ADVANTAGES OF COMPRESSION.

Of course, I was interested in his clamp, as he calls it; and surely it is a clamp. It is simply a small case for holding 16 sections, and the same are pressed together with thumb-screws and a follower. Messrs. Crane and Manum both use a similar arrangement; and I am satisfied, from what I saw at their places, that it is certainly an advantage in compressing the sections. In the apiaries I visited I noted *particularly*, that, where *compression* was used on the sections, there was a most *decided lessening of the propolis accumulations* on the sides of the sections coming in contact. The time saved in scraping afterward will more than save the expense of compression. We regard the wedge and follower so important that we have put it in all the supers for the Dovetailed hive.

Not the least advantage of the follower and wedge, or the thumb-screw, as the case may be, is the facility in removing sections; by simply loosening the thumb-screw or wedge, the sections are ready to be slipped out of the case.

MANUM'S LEATHER-COLORED ITALIANS.

That evening, while Mr. Manum was doing his chores, I strolled out among his bees, and raised the covers over his hives, and, although the air was a little chilly—enough so to make the bees a little irritable—I pulled up the covers and looked down upon the bees—yes, those leather-colored chaps that know how to gather honey. They were as gentle as kittens. I would not have blamed them at all for showing a little fight for coming upon them at such an inauspicious time. In fact, their general appearance is much like that of bees from imported queens, and their temper was strikingly the same. I do not say this to puff up our imported stock, but simply that Mr. Manum, through a careful selection of years, has raised a lot of bees possessing strikingly the characteristics of those reared in mother Italy. One thing that struck me as I was looking over those bees from those hasty glances, was the fewness of burrs-combs. This matter has been already touched upon in this journal by Mr. Manum and myself elsewhere; see page 839.

MANUM'S CHAFF HIVE.

Although Mr. Manum had carefully described his hive, with appropriate illustrations in GLEANINGS, some time ago, I never understood before that he uses virtually an outside protecting shell over and around the ordinary brood-nest—single wall. His "brood-box," as he calls it, is made of $\frac{3}{4}$ stuff, and sits right down on the large bottom-board for the outside protecting-shell. To enter this hive, the bees pass under the bottom-board through a hole. The outside shell is simply a large case having a hinged cover, leaving some three or four inches space around the brood-box, or, as we might call it, an ordinary single-walled hive. Common planer shavings are poured in around the brood-box until they are level with its height. When the bees are packed for winter, an ordinary cushion sits down over the whole.

In very many respects I like Mr. Manum's hive. If he should so prefer, he can remove his bees in the ordinary single-walled hives, and afterward bring along the outside shells. In other words, he is not obliged to lug along a great big hive in order to carry an ordinary-

sized colony. He simply lifts out its inside, and then he can lay the narrow outside cases in a large wagon having a hay-rack, or any thing suitable for carrying something so bulky.

It was getting dark, so I could not pursue my investigations further, hoping to reserve the rest for the morrow. That evening Mr. Manum and I had one of those unconventional bee-conventions all by ourselves. His son Fred, who has charge of one of his apiaries, was present part of the time. When I asked where he was, his father smilingly said, "When I have visitors, and we begin talking about bees, he is up and off."

I have no doubt that Fred is as I used to be. Before I forget it, I might say that he is a young man 21 or 22. He is quite an expert apiarist, and is one of those fellows who like to have every thing neat and tidy, but he does not like to talk bees everlastingly. His father seems to have lost none of his old enthusiasm; and as each new subject was brought up, his face would light up with pleasure, for he always has something practical to relate. We did not sit up and talk *all* night—no; we went to bed at a late hour, and the next morning we were ready for business. But, oh dear! it was raining, raining, raining, and it looked as if it would continue all day, and it did. We employed the time profitably. I think, by talking; but, how I *did* want to go out into that apiary again! Finally, along in the afternoon, with umbrellas and gossamers, we went out into the yard in spite of the rain, and then I had a chance to see those leather-colored bees a little more plainly. I asked Mr. Manum what he thought of the golden Italians. They are too short-lived and delicate for the business—at least for him. He did not object to their being yellow, but, as a general thing, the bees that do the best work are after the darker order.

As was explained by Mr. Manum, he had designed to take me among the bee-keepers of that section, but it rained so furiously that that was out of the question, and I bade my friend good-by, expressing the wish that I might come again and make my visit a little longer.

I found Mr. Manum to be all that I expected, from his writings. He is progressive, ingenious, systematic, and thoroughly practical. I said "systematic." He is extremely so; and this may account in no small degree for his success. From what I saw of him I should judge he has a very pleasant faculty of getting along with his boys, and making them do just what he wants them to do, with few or no rebukes. In fact, there is nothing I should like better than to work a season with him myself.

As I am about to close I regret that more bee-keepers can not have the time and money to visit each other more than they do; and I hope, therefore, that I can make these notes more of a permanent feature than I have done heretofore. If there is any thing that our readers wish to know, that I have not sufficiently touched upon, please write, and I will either give further particulars or ask the bee-keepers directly concerned to answer it. This finishes my notes of travel on my eastern tour. Next time I hope to tell you something about the Dandants and Dr. Miller.

KEEPING RECORD OF HIVES.

HOW FRIEND MUTI-RASMUSSEN DOES IT.

Friend Root:—During this honey season I have kept track of the work in the apiary by using your slate tablets in connection with small stones in different positions on the hive-covers. On the side of the slate, turning toward the hive, I note any thing that has to be pre-

served for the permanent record of the season; as, when super was put on, when emptied, etc., which gives me at the end of the season a complete record of the doings of each colony, to be entered, if desired, in the record-book, which will enable me next year to decide which queens to breed from, which colonies must be requeened, etc. On the side of the slate facing outward I simply write in large figures the date when last I opened the hive; and the stone or stones on the cover tell me of the last work done, or the progress or condition of the colony when last examined.

This system would be perfectly satisfactory if only the constant change of date in writing could be avoided. The permanent record must, of course, be written, and for this reason I would continue the use of slates, though in a more limited degree. But the ordinary work with or examination of hive or super can be recorded by the position of the stones, of which each bee-keeper can form a code of his own, while the date could be changed without the necessity of writing, by using a *date-card*. I have thought of using your queen-registering cards for this purpose; but the trouble is, that the date figures are so small that one has to stoop low to read them. I would have the figures so large and plain that the bee-keeper can read them without difficulty, as he walks along in the rear of the hives; larger, if possible, than those on the sample card. As the seasons vary in different parts of the world, the abbreviated names of *all* twelve months should be printed in the other circle. The date-card should be about the size of an ordinary postal card, and should contain only the two circles for the months and dates, and a place for the number of the hive—nothing else. I presume that pins can be obtained, long enough for the larger circle. Black pins would be best; hairpins cut in two might answer the purpose.

Where one has a large number of colonies to go over in a day it is quite an item to be able to avoid much writing, particularly when the hands are soiled with honey or propolis.

I think these cards will prove a boon to the bee-keeping fraternity, if you will get them up and keep them in stock, at, say, a cent each, 75 cents per hundred, \$5.00 per 1000, or whatever you can make them for. I myself would use 150 or 200 each season. If you think favorably of it, please get them ready for next season's use.

In regard to the position of the stones, I will give my present system as used, while the supers are on the hives, viz.:

7	6	5
8	9	4
1	2	3

Rear.

- 1, emptied first time.
- 2, emptied second time.
- 3, emptied third time.
- 1 (2 stones), emptied fourth time, etc.
- 4, doing nothing.
- 5, sections not yet capped.
- 6, ready to come off in about a week.

- 7, ready to come off in a few days.
- 8, super put on (see date).
- 9, look at the slate.

This may be varied to suit each individual, and the same marks may have other meanings when no super is on the hive. To me the system has been of great benefit, as I could read at a distance the record of each hive, and it would have been perfectly satisfactory, if I could have had the use of the date-cards.

I have used the stones for several years, and am aware that others are using them also; but the date-cards are a new idea of my own, and I hope ere long to see them in general use.

WM. MUTH-RASSMUSSEN.

Independence, Cal., Aug. 4.

Friend M., I am glad to see you developing our old queen-cards that I was so enthusiastic over when they first came out. Since you suggest it, we can easily print these cards the size of a postal card, and we can also print the numbers on from 1 up. Black pins can be had at the millinery stores. Just ask for mourning-pins, and you will get exactly what you want. Now, before we set up the type to print these, we should like to know how many want them at the price you mention. We can make the numbers large, plain, and black; put them in packets of 100 and print them on waterproof paper or cardboard, at the price given, providing 100 or more will take a pack of cards.—Your idea in regard to the stones is very suggestive. It reminds me one of that queer science called "mnemonics."

THE BEE-ESCAPE PREFERRED BY H. L. JEFFREY.

THE OLD PERPENDICULAR CONE THE BEST.

I send you a draft of a bee-escape we like best. The sides and ends are 5 inches deep. The ends are $\frac{3}{8}$ inch thick, and are rabbeted out $\frac{1}{8}$ inch deep. The sides are $\frac{1}{2}$ inch thick. The escape-board is also $\frac{1}{2}$ inch thick, 13 inches wide, 19 long. It is to be let down into the end rabbets, leaving it $\frac{3}{8}$ below the top edge when in place. Make 8 holes in it 2 inches in diameter, and bend the upper edge to 3 inches. Make the cones so that they will be about $2\frac{1}{2}$ inches deep when formed with a scant half-inch at the apex. Fasten these from the upper side, then make another set of cones, that will be 3 inches deep, from a square of wire cloth, and have it about an inch larger in diameter than the inner cone, and make the egress $\frac{1}{2}$ inch in diameter. Nail this on the under side by turning up the corners. If thus made there will be a full inch space below the cones above the top of the frames, and plenty of room for nearly a swarm of bees on the under side of the escape-board. The wire cloth can be cut 5 inches square for the cones. By using the deep rims and 3-inch cones, two or three crates can be placed upon the escape at one time; but if only one crate is

[THE FORM OF ESCAPE USED BY JEFFREY.]

taken from the hive at one time, an escape with a $3\frac{1}{2}$ -inch rim and $1\frac{1}{2}$ -inch cones will do. But give me the deep one every time. I have used two sorts, one with the board flush with the top of the rim for crates, with bee-space under side; and for the crates with boxes flush with the bottom, the escape has the top bee-

space. I am indebted to Mr. Reese for this escape.

H. L. JEFFREY.

New Milford, Ct., Nov., 1890.

Our engravers have made the super too deep. If half the depth, its proportion would be about right. There is no question but that this escape will work. In our special number, some time ago, on bee-escapes, it was shown that a space *below* the escape, of *two or three inches*, was a decided advantage. There has never been any question as to whether the original Reese would work; but because it stuck up in the way, the "horizontal" was devised by Mr. Dibbern. His pear-shaped model has worked very nicely with us, and is much less liable to be damaged than the perpendicular Reese. The latter form is cheaper to construct.

STRAY STRAWS.

EDITED BY DR. C. C. MILLER.

Charming fall weather.

It seemed lonesome without the Michiganers, Prof. Cook and editor Hutchinson, at Keokuk.

Henry Alley believes in closed-end frames, and will hereafter use 7-frame hives.

Alley wants to spot the fellow who invented pulverized sugar and honey for shipping-cages.

A prominent manufacturing concern takes control of one of the bee-journals Jan. 1. "Which one?" I won't tell.

The name "International American Bee-association" has been changed back to "North American Bee-keepers' Society." Good! It's to be incorporated.

Is it because Doolittle raises capital queens that he always says "Queens" in his book, or did his publisher run out of lower-case q's?

I took 27 colonies into the cellar Oct. 28. The last of my bees were not taken in till Nov. 8. Four are left out for experiment.

Elwood, the new president of the N. A., is a man of weight—some 200 pounds of it. And that's not the only kind of weight he has.

Hutchinson thinks an editor and publisher should keep out of the supply-business—if he can. Can he? The *Review* isn't very old yet. It's a good paper, though.

Delegates of affiliated societies sat on the platform at Keokuk. If ever the society becomes truly representative, it will have to meet in a hall whose floor is *all* platform.

My bees don't hang in such large clusters under the bottom-bars as they did last winter. They seem as heavy with honey and as strong in bees, but perhaps they are not.

The Ontario Bee-keepers' Association not only sends a delegate to the N. A. convention, but pays his expenses. Canadians can't brag with us, but sometimes they beat us in having something worth bragging about.

President Taylor and Vice-president Secor are alike in one respect, both having faces so barricaded with beard that they look as solemn as undertakers. But there's lots of fun back of the barricade.

Does the roaring of a particular colony in the cellar mean any thing wrong? Doesn't every colony have a periodic rousing-up, to turn over in bed, take a lunch, or something of that sort?

Samuel Crishman, superintendent of Rhode Island Experiment Station, after several years' trial, recommends Simmons' dry-sugar feeding

in spring—C' sugar, put in a feeder where the heat and moisture of the hive are confined.

In his paper at Keokuk, Rev. W. F. Clarke says I called him "long-winded," and makes the secretary his authority for it. I don't know that I ever *said* so. Is one of them a mind-reader?

The old vice-president and secretary of the N. A. were re-elected, but E. R. Root beat me for treasurer. That's always the way. Whenever I get at any thing that has money in it, I always lose my job.

What's the reason that that \$5000 has been kept so still? I mean that \$5000 to which Prof. Cook referred in his essay at the North American convention. Ought not the bee-journals to tell us all about it?

Isn't there a fading-out of the strong advocacy for upward ventilation? A good many of the former upward ventilationists, myself among the number, now want every thing glued up tight on top, in winter. It's lots handier. But larger bottom ventilation has come.

Is it true, as a general rule, that, the nearer you get to a lot of bee-keepers, the brighter they seem? I had no idea there were so many bright bee-keepers within hail of Keokuk. I was disappointed in not seeing Dibbern and some others there.

Three-sixteenths of an inch is what the *Api.* calls a bee-space. That's the least space I believe in which a bee can stand up straight; and if any one attempts to make it less, so the bees will have to get down on their hands and knees, there'll be trouble.

UNITING.

Considerable testimony is given in the *British Bee Journal*, to show that bees may be readily united by simply dredging the bees of both colonies with flour, whether they be on or off the combs. Some say they have practiced it for years. It's easily tried.

The *C. B. J.* reports two cases in which a cluster of bees without combs or stores has hung a good many days in the fall "without visible means of support," but bright and lively. It raises the question as to whether it may not be a good plan to keep bees in this condition "between the close of the surplus-honey harvest and the putting of the bees into winter quarters."

H. Alley and E. L. Pratt agree that colonies heavy with stores at the close of the honey season consume these stores, and are no better off in the fall than those that were light. Alley says, "We have come to the conclusion, that, at the end of the honey-flow another season, we shall remove nearly all the honey from the brood-combs, and thus compel the bees to make their own living from day to day. . . . It strikes me that this plan for retarding brood-rearing and also in economizing the consumption of stores, will be successful. If necessary to feed back in the fall, the honey will be on hand for the purpose." This is closely in line with D. A. Jones' swarm hanging with no combs. It may lead to something.

Can't GLEANINGS put the name of each writer at the *beginning* instead of the *end* of his contribution? It isn't pleasant to wait till a man is through talking before you see who he is. Also, it would be a comfort if "A. I." or "E. R." were signed to all the editorial comments. It's a bit confusing sometimes as it is.

The *Apiculturist* commends A. I. Root for paying \$50.00 to Benton for the benefit of his experiments in shipping-cages. I wonder whether Bro. Root's opposition to patents doesn't arise from a desire to crush out the government and monopolize the business. In several cases I think he has paid more for in-

ventions than a government patent would have brought.

THE THICK-TOP-BAR BOOM.

This gets an encouraging pat on the back from the *Apiculturist*; and C. B. J. Heddon doesn't say any thing about it lately—lying low till he sees the collapse of the whole thing, when he may repeat his Chicago statement: "When you throw up a brick, and it stays up without ever coming down, then you may expect to dispense with slatted honey-boards."

THE INTERNATIONAL BEE-ASSOCIATION.

NOTES BY ERNEST, CONTINUED FROM PAGE 809.

W. Z. Hutchinson, on account of ill health, was not able to be present; but Dr. Miller read, in clear and distinct tones, his paper, entitled

APICULTURAL JOURNALISM.

Mr. Hutchinson touched upon the growing tendency of the times toward *specialism*. With the need of specialty in production, came the need of specialty in periodicals; and why not in bee-journals? He did not believe it paid to "mix in" other specialties. He would give attention to quality, and would keep out the trifling experiences of beginners. The author's name he would have at the head of the article, so as not to be obliged to turn over the leaf to see who the writer is. He opposed the idea that *all* should write briefly so that all may be heard from. A long article he would welcome just as much as a short one, provided the former contained valuable matter in proportion to its length. Advertising matter in bee-papers he thought should pertain to bees. He would not have his advertisements from bee-men overshadowed by buggies, patent medicines, trusses, etc. He would have the journal stopped at the time paid for.

At the conclusion of the paper quite a discussion arose. Dr. Miller wanted the buggies and other *useful* things, because it helped to make a better paper. Mr. Newman argued that the advertisements of useful articles, whether pertaining to bees or not, were the life of a periodical. A bee-paper could not be supported without them. The opinion seemed to be abstracted from the paper, that Bro. Hutchinson would cast *all* bee-journals from the same mold. It was insisted that each journal should retain its individuality, and that, for any one of them to follow exactly the policy Bro. Hutchinson outlined, would be detrimental to their best success.

Dr. Mason read an essay on the apiarian exhibit at the Columbian World's Fair in 1893. He gave some correspondence between himself and the Exposition Management. He would have all the exhibits from the whole world grouped together; then the exhibit from each nation and State by itself, with a superintendent to assign location and space, with a general oversight over all. It would add much interest to the display to have the name of every article placed upon it, so that an unsuspecting public would not call beeswax maple sugar, extracted honey maple syrup, extractors churns, etc. If possible, there should be an apiary on the grounds, and with a large display of growing and blossoming honey-plants. He recommended that the bee-keepers of the several States should apply for an appropriation. After reading the paper, a committee was appointed, composed of Dr. Mason, R. McKnight, and T. G. Newman, to confer with the authorities of the World's Fair in regard to space, etc., for the necessary exhibits of honey and apicultural appliances.

R. McKnight gave us some good suggestions

at this point. He had had long experience in this line. A great deal of money is needed for exhibits, and this ought to be furnished by the different States and provinces. He thought the bee-keepers of each State should ask for appropriations from their legislatures.

Dr. Mason said that, at the International Exposition at New Orleans, the State of Ohio gave \$500 to a bee-keeper to take charge of the State exhibit, and he proposed to ask the State of Ohio to give \$1500 for Ohio's bee-exhibit at the Columbian Fair.

Dr. Mason was recommended by the society as a suitable superintendent of the exhibit for the United States. Certainly there can be no one better qualified for that place, within our own borders, than he. He is interested as no one else is, in apicultural exhibits, and he is the man to have charge of the matter.

THE INTERNATIONAL BEE-ASSOCIATION—ITS PAST AND FUTURE.

This was the subject of a very interesting paper by W. F. Clarke. He referred to Mr. T. G. Newman as being the historian of this society, and the splendid work he had done for it. Prof. Cook was the father of it, and he thought we owed as many thanks to him as to its historian, for he was not only the author of its being, but he had helped to make its history. One of its first works was to elevate father Langstroth to the pedestal of honorable distinction. At the outset of the organization an attempt was made to start a rival association; but by judicious management the two were amalgamated, and father Langstroth was made president of the combination. The presidency next fell to the late Moses Quinby. Of him he said, "If there ever was a just man on earth, Moses Quinby was one. His services to bee-keepers are second only to those of Rev. L. L. Langstroth." He would emphasize the influence the association had in keeping reputable bee-keepers at the front. He would urge that the association be more representative in character. The only defect in it was, that there were too few "wise men of the East" present; and but for the kindness of the Ontario Bee-keepers' Association he himself would not have been present. They had sent him as a delegate, and paid his expenses, and they proposed to continue to do so. He held it up as an example for State associations.

At the close of the paper Mr. Newman emphasized Mr. Clarke's point, that the association should be *representative*, and that State and Territorial associations should send delegates, and *pay their expenses*. Bee-men generally can not afford the outlay for themselves. This matter was touched upon elsewhere in our last issue, and I hope our associations will take the matter seriously into consideration. Let there be a delegate from each State to our national associations, and, by all means, pay his expenses. It seems to me that a State society that can not do it is not in a very flourishing condition financially. I believe some one in the meeting suggested (perhaps it was Mr. Newman) that, if the money could not be procured through the society, the individual members themselves chip in and send their delegate.

AMENDMENTS TO THE CONSTITUTION.

In some of our earlier sessions there was considerable discussion in regard to the constitution, and its need of revising on some points. Mr. Newman, upon consultation with a few of the officers, introduced several amendments, one of the most important being the change of the name of the association. It had been, heretofore, International American Bee-association; but it was objected, that "International" was too big. Heretofore the territory of Canada

and the United States only has been included. It was objected, also, that we are not an association of bees; therefore the old name, North American Bee-keepers' Association, was recommended and adopted.

FOUL BROOD.

Foul brood was the subject opened by a voluntary contribution by Allen Pringle, president of the Ontario Bee-keepers' Association. He detailed what Ontario bee-keepers had already done in securing the passage of a foul-brood act, and of an inspector, under the pay of the government, the details of which we have already given in our columns. He gave the method of cure which we recommend in the A B C book, and have from time to time given in these pages.

After the paper the convention discussed, pro and con, its cause. Some argued that it might start from chilled or decayed brood; but I think it was proven that the disease can not start from this source. It might be a favorable medium; but unless the germs were there in the first place, it could not propagate. Some thought it was *not* necessary to scald the hives; but your humble servant told them that he left 40 hives without scalding, and every one of the number, in six months, imparted the disease. There is no practical method of disinfecting, except by boiling every thing having been in contact with the disease, except, of course, the bees. They, if they consume the diseased honey in their sacs, will not again transmit the trouble.

FULL SHEETS OF COMB FOUNDATION VS. STARTERS IN THE BROOD-CHAMBER AND SURPLUS RECEPTACLES.

This was the subject of Eugene Secor's essay. He started out by saying that one swallow does not make a summer, and one experiment does not establish a theory, always. He did not pretend to know a great deal about the subject, but for several years he has used full sheets of foundation in the brood-chamber. The advantage was, that he had secured all worker combs; and the disadvantage was, that it increased the cost of every colony. Then he decided to let the bees build their own combs. Last summer he met a setback which he had not experienced before. The nectar was so scarce that the bees built scarcely any comb up to the opening of basswood. That came in such sudden abundance that some of his best colonies built almost entirely drone comb below. If he had foreseen this, and had provided them with full sheets of foundation, he was not sure but that the bees would have gnawed it full of holes, and filled it full of drone comb. With the present high price of foundation, and the price of bees, he was somewhat doubtful about the advisability of using more than a starter in the brood-chamber. With comb honey in sections he would use full sheets of the very thinnest and best foundation. In extracting supers he liked full sheets.

A lively discussion followed the reading of this paper. Dr. Miller was asked about wiring foundation, and he replied by saying, "I don't know." When we wire foundation, he said, we have it in the middle, and can handle frames more easily. When a vote was taken, it was shown that 28 used foundation, and 25 did not. They kept on arguing until it was suggested that we were off from the question. The question, "How many use full sheets in brood-frames?" showed that 30 voted yes, and that 20 used only starters, and only 3 none. A good many others did not know what they did want—that is, they had not settled whether they want to use full sheets, starters, or no foundation at all. As to the matter of building worker or drone comb

without foundation, Mr. Axtell said he uses special colonies. He takes out all the combs, and makes them build another entirely new set; and by selecting those with young queens he gets worker comb. If they build one or two combs they will build drone-cells. Mr. B. Taylor corroborated this.

FIXED DISTANCES.

Along about this stage of proceedings, "fixed distances" was discussed by your humble servant. As I have already given my ideas on this subject, I will not repeat them here; but I was surprised to see that there seemed to be in the convention a recognized need of fixed distances. Seventeen, by a show of hands, used fixed distances of some sort, either in part or in whole; 35 used hanging frames altogether.

THE QUESTION-BOX.

This was introduced about this time.

Can first-class honey be produced in sections without separators?

A good many answered yes.

What is the best method of preventing bees from sticking the upper stories of hives to the lower ones with propolis?

Use close and tight-fitting joints. A little piece of grease rubbed on the places of contact will help very materially to keep propolis off.

What shall we do with our swarms of bees when not wanted?

"Return them to the old stand," Dr. Miller said.

Is there any difference in color and quantity between honey extracted from light-colored combs and that extracted from dark?

Dr. Oren answered no. He had used combs 15 years old, and the honey harvested from them is as nice as that from new combs.

Is spring dwindling worse in the cellar than outdoors?

The general consensus of opinion seemed to be that it was. During severe winters, bees do better indoors, and in mild winters outdoors.

What is the objection to a house-apiary?

Mr. Hambaugh replied that he had used one, and abandoned it.

THE REQUISITES NECESSARY TO SECURE A HONEY CROP.

This was a paper by Prof. Cook, and in his absence it was read by Mr. Newman in his characteristic clear voice. After regretting his absence, Prof. Cook referred to the difficulty of handling such a theme, and that it was not of his own choosing, and mentioned the fact that Dr. Miller would say, "I don't know." This came in very "pat" right here, because, during the convention, the doctor's "I don't knows" were a subject of banter. Getting down to the theme, Prof. Cook urged the necessity of successful wintering, and giving good protection to bees in the spring. His experiments during the past few years have proved conclusively that protection pays an exceedingly good profit. Chaff hives will do, but he prefers an outer case and excelsior packing. We must have prolific queens. He was not sure but it would pay to requeen an apiary every year, or at least every second year. Strong colonies when the season opens up, are another requisite. And then he came to the question, "Why do the flowers refuse to secrete nectar?" He would like to quote Dr. Miller's modest sentence—"I don't know." He said, that last year we had the rain and warmth, so the usual conditions were not lacking. The only explanation he could offer was, that, the year before being so terribly dry, the young plants were so blighted that they could not recover, so they were unable to perform their usual functions. He cited the fact that a young calf or colt partially starved never fully recovers.

At the close of the essay Dr. Miller said, that, whether Prof. Cook's theory were correct or not, the result would be the same. His outlook during the past season had been good—neither too wet nor too dry. Some one asked, "What was the cause of the failure?" Dr. Miller promptly responded, "I don't know." The doctor managed to bring in this modest sentence very adroitly a number of times, and each time laughter and general fun was the result. A good many stated that they had all the favorable conditions, and yet nectar was wanting during the past season.

ARE ITALIANS OR HYBRIDS PREFERABLE IN AN APIARY RUN FOR HONEY?

This was the topic of an essay by C. F. Muth. He gave good proof that Italians are superior. They are more handsome, they are gentle, and give as good results as any, in honey. According to his experience, the Italians give him the largest crops. And the pure stock are always best supplied with winter stores after the winter season.

As the time was limited, discussion was cut off, and we listened to the report of the General Manager of the Bee-keepers' Union. Mr. Newman showed, by nearly a score of instances, that the Union had always been triumphant. It had either won the suit, or had brought such influence to bear that the enemies of the bees dropped the matter without litigation. The most important thing of all, it seems to me, was that the *late* cases against bee-keepers have been killed by a recent decision of the Superior Court of Arkansas. The Bee-keepers' Union has nearly a score of *precedents*, and the valuable aid which this gives to the industry of bee-keeping in all future litigations can not be overestimated.

The following officers were elected for the ensuing year:

President, P. H. Elwood, Starkville, N. Y.; Vice-president, Eugene Secor, Forest City, Ia.; Secretary, C. P. Dadant, Hamilton, Ill.; Treasurer, E. R. Root, Medina, Ohio. The next place of meeting is to be at Albany.

In conclusion I can not refrain from saying that this meeting was one of the best, if not the best, in enthusiasm, good-natured banter, in attendance, in the *practical* character of the discussions, in the character of the *men* and *women* who went, and last, but not least, in the *business* done, and recommendations made, in the history of the association; and I hope this is only a side-show of the good times coming, when the association shall be incorporated under the laws of Illinois, and when the membership, instead of its present floating character, shall be permanent, with a long list of life-members, and annual members who keep up their dues, whether able to be present or not.

HEDDON'S HONEY.

WHAT MADE IT SELL SO FAST?

Mr. Root:—You remember the little advertisement I placed in your paper a short time ago, offering my this season's crop for sale. Well, sir, it is all gone; and as I suppose you do not charge any thing for back-action advertisements (I know we do not in our newspaper), I want you to let me say in this article that my crop this year, of about 20,000 lbs., is all gone, and I hope all my customers will see this and not put themselves and me to trouble and expense by ordering from me this season. If cards of thanks are in order, allow me to thank those who have patronized me, and, at the same time, perhaps I can do your readers and my brother

bee-keepers some good by telling them how I came to sell my crop so quickly.

First, I have learned how to (and do) take pains to produce and care for my extracted honey, after taking out, in such a manner that it is ripe and fully equal to any comb honey in flavor and consistency. At least, this is what I *aim* to do, believe I do do, and nearly all of my customers who have expressed themselves on the subject (and most of them have) say I do; and when they once sell this honey to their customers, they clamor for more; and nearly all other extracted honey found upon the market will not fill the bill, because it is not rich and smooth like thoroughly ripened honey. To be sure, it costs a little more to produce it this way, but not so very much either, when one knows just how to do it.

Another point is, that, notwithstanding the short crop and scarcity this season, I have *kept the prices down*. This has given me a broader sale, and consequently a better chance to introduce my goods, which I have found in all lines of business it pays to have of such quality that they advertise themselves. Just here let me say to all supply-dealers, no matter what line of goods, I believe the cheapest way to advertise and build up a trade is to furnish such goods as will give the best satisfaction clear to the end.

I believe I have touched upon some of these points in my former articles; but as new bee-keepers are coming into the field, and you are getting new subscribers among the old ones, if you desire I will furnish you an article on the subject soon, giving a full account of how I manipulate the bees and hives.

Dowagiac, Mich., Nov. 14. JAMES HEDDON.

EXPORTING QUEENS.

G. M. DOOLITTLE TELLS US WHAT HE HAS DONE.

A letter came to hand a few days ago, from New South Wales (so I take it from the print on the postage-stamps). The name of the sender is so poorly written, together with the post-office address, that I am not sure what it is; and as the writer says he is a reader of GLEANINGS, I will, with your permission, Mr. Editor, answer through the columns of GLEANINGS. Before doing so, however, I wish to say a word or two regarding this matter of writing addresses when sending letters. The *address* is the most important thing in any letter. No matter how important questions may be asked, or how many goods you may order, you can not obtain what you are after unless you fix it so that the one who is to accommodate you can make out where to send what you want, so it will reach you. If your address is not printed on your envelope or stationery, you should take *extra* pains to write your address plainly, even if it takes you longer to write that address than it does the body of the letter. One thing occurs to me just now: Write your address the first thing in beginning your letter. By so doing you will not forget it, as some are prone to do, and, what is of more importance, you will write it much plainer if written on the start than you will afterward. Many of the letters which I receive I can read very well for the first few sentences; but as the writer warms up, or gets tired, as the case may be, he pays less and less attention to his penmanship, and the last end winds up with little less than a scrawl, name and all. I will say no more on this subject, for fear I may get to scolding, except to say, that, when you get to a point where you have to answer many letters daily, if you ever do, you will look at things in a different light along this line than you do

where you write a letter only as often as once a week or once a month.

In the letter alluded to above, I find the following: "It has just come to my knowledge that you have successfully exported queens to Australia; and as I am anxious to obtain some of your stock, would you let me know if the information I received is correct?"

I am sorry to say that the information is *not* correct. Some five or six years ago, a party living in New Zealand wished me to send him some queens. I wrote him that it was very doubtful about my getting them there alive; but I said if he would stand half of the loss, if the queens failed to come alive. I would try the matter by way of experiment. To this he agreed. There is only one proper time to try this experiment from this State, and that is in October, this being as late as we can risk shipment here, on account of cold, and as early in the spring as they can well be received in Australia.

When the proper time arrived, I prepared the queen to be sent, to the best advantage as I considered it, and started her. She was just 37 days *en route*, and reached there alive, so that she "kicked around a little," according to the information I obtained from my friend, but soon died. As he wished to try again, we did so; but instead of the second going in 37 days, she was 72 days on the way, and, of course, died long before she arrived. In thinking of these long journeys in the mails, it must be taken into consideration that the life of the worker-bee, under the most favorable circumstances, is only about 45 days during the summer months; and when we come to place them under as unfavorable conditions as they are while confined to the narrow limits of a queen-cage, it is not surprising that they should not live out their allotted time. After the workers all die, the queen does not survive a great while, so that I consider it an impossibility to get a queen to New South Wales alive, with only the set of workers that are placed with her to start with, especially as the letter I am answering was 54 days on the way. If, after the queen had been on the way about 20 days, some practical apiarist could receive it, open the cage, and put a fresh escort in for the queen, seeing at the same time that the candy was fresh and in abundance, and after the next 20 days the same thing be done over again, I think there would be no doubt but some queens might be sent alive from here to Australia. During the last year I have received queens from Italy for parties in California by mail. I placed them in fresh cages, and gave them fresh bees, thereby getting them through in fine order, when only failure had been the result of former trials. I have also assisted parties from the West in getting queens over to Ireland in the same way.

THE NAMELESS BEE DISEASE.

After speaking some good words about an article of mine in GLEANINGS, and telling how one of their "great lights" in Australia agreed with me, the writer goes on to tell how, at a meeting "in this colony," called for "the advancing of the interests of bee culture, etc.," it was "asserted that the nameless, or shaking bee disease, is nothing but a species of intoxication, arising from the consumption of fermented pollen and honey by the bees," and asks, "What do you think about it?" He seems to think, that, if there was any truth in this assertion, the drones would have the disease as well as the workers. This would be so if the trouble were in the fermenting of honey; but if it was fermented pollen, then the drones would not have it, for, as far as my experience goes, mature drones never eat pollen nor have any thing to do with it. I should not like to express a positive opinion in the matter; but this one

thing I have noticed: That in all cases of the nameless disease which I have seen in my own neighborhood and elsewhere, it always disappears with cold weather, and does not again appear till warm weather comes to stay, whether the queen of a colony is removed or not. I also had one case where the removal of the queen did no good, as the disease kept right on till cold weather came, when it disappeared. This showing, only in warm or fermenting weather, would give a little coloring toward the fermentation theory. G. M. DOOLITTLE.

Borodino, N. Y., Nov. 15.

Friend D., I am very glad to know that you have done so much in this line. I came to the conclusion, long ago, that the limit of time that a queen might be out of the hive with a single escort is just about where you put it. In regard to the nameless bee disease, you may be right; but we have almost always, if not always, cured it by giving a new queen.

EIGHT VERSUS TEN FRAME HIVES.

IN FAVOR OF LARGE HIVES.

In Oct. 1 GLEANINGS you call upon the California bee-kings to give their experience with eight and ten frame hives. While I am not a bee-king (a drone) I have had much experience with the two sizes of hives, my apiary of nearly 400 stocks being about equally divided between them. I produce only extracted honey, and all my remarks relate to the production of that article.

Until the past two seasons I kept bees in a very poor locality, where a good honey-flow was unknown. There I thought the eight-frame hive was plenty large; but after experiencing a good honey-flow I concluded that the ten-frame was too small, and twelve would be about the right size. In California we do not storify and extract at the end of every season, *a la* Dadant, but extract every week or ten days. While eight frames give brood space enough for most queens, an eight-frame super will not hold as much honey as a strong stock can gather in a week during a good honey-flow; and, if extracted oftener than once a week, the honey is unripe and inferior. Two supers are too much room, and a nuisance besides. Some of my best stocks would fill every cell full in less than a week, and would of necessity be idle until extracted from. In these cases the ten-frame hive, having two combs more to fill, would have from 10 to 12 lbs. more honey. A twelve-frame super would have been about right for many of my hives. These large supers are objectionable, however, as, when first put on in the spring, and before being occupied by the bees, they make the hive almost too cool; and too use dummies or fillers with them is another nuisance.

I believe the old discarded Long-Idea hive is the proper thing for extracted honey in California. It is the best non-swarmling hive extant. The most prolific queens can find a cell for every egg they can lay; and, when extracting begins, as many of the combs can be used for storing as are required. When building up in the spring, by the use of a division-board the hive can be so contracted as to meet the requirements of any stock, and the remainder of the combs are where they will be protected from moth, mice, and robber-bees, and right to hand when wanted. The hive, however, will require a little more lumber than a two-story hive with the same number of frames, and I believe the heat in them will be greater. WM. G. HEWES.

Newhall, Cal., Nov. 6, 1890.

For extracted honey, and in your locality, you are doubtless right. Recognizing the needs of just such as you, we offer in our catalogue both the eight and ten frame hives — the latter at a slight additional cost. But the vast majority of apiarists and localities demand the eight-frame size; indeed, J. F. McIntyre, of your State, gives some pretty conclusive arguments for the smaller hive. See page 674.

THE CLARK SMOKER.

THE SMALL VERSUS THE LARGE TUBE: BEST FUEL.

We have used the Clark smoker for several years entirely. We like it on account of throwing the smoke with so much force. It has had two serious objections, however. It would drop creosote, and leak fire. You may say, "Clean your smoker." I did clean mine. In fact, I spent so much time cleaning that I am pretty sure Dr. Miller thought me very fussy, although he was too kind to say so. But still the black sticky stuff would drop over my clothing and on our nice white sections when we least expected it, and proved very annoying indeed. Especially was this true if the smoker was heated very hot. This year we have used the improved Clark with the large tube, and have not had one particle of trouble with creosote, and you don't know what a comfort it is, unless you have been bothered in the same way. The large tube needs very little cleaning; still, it is better to clean it occasionally. A stick pushed through the tube has been recommended as a means of cleaning it. Of course, the stick must be green, so that it will bend readily. We dislike it, as, in this way, all the dirt will be sent into the bellows. A heavy wire, curved about the same as the tube, the point flattened and bent, forming a little hook, makes a very good tool to clean it with.

Another improvement is a piece fastened on the smoker in such a way that the lid slides inside of it, making it very close and snug, so that no fire can leak out. There was one objection to this, however—there was not enough draft to keep it burning. To obviate this, Dr. Miller punched several small holes in the lid, not large enough to emit sparks, but sufficient to give air enough to keep it burning, and it worked like a charm. In using the Clark smoker without the improvements, I had a great deal of trouble about burning my clothes, often large holes being burned before I discovered it. This summer I have not burned a single dress, and only one apron, and that was the result of my own carelessness, as I had left the lid open. The feeling of security is worth a great deal. Mr. Root has my heartiest thanks for the improved smoker.

Another point in its favor is the increased durability. One with the large tube will, I think, outlast three of the others. We have used two throughout the season, and they are as good as ever, with the exception of the one Dr. Miller stepped on, which is slightly demoralized.

For fuel we use, mainly, turning-lathe shavings made from hard wood. Some time ago Mr. Root sent us two barrels of excelsior, which was very nice indeed. It does not last as long as the turning-lathe shavings, but is very good to light with, as it catches so quickly. The two mixed make a very good fuel. The very best thing to light a smoker with that we have ever tried is a small piece of saltpeter wood. On a very windy day the matches will go out almost

as soon as lighted; but if the least bit of a flame touches the wood it will burn, and not die out either. It certainly is a great saving of time and patience. We do not like to get along without it, and keep a small box of it at each out-apiary. Perhaps some one may like to know how to prepare the saltpeter wood. It is very easily done. Take $\frac{1}{2}$ lb. of saltpeter; put it in a jar with a gallon of water. After your saltpeter has dissolved, break your rotten wood in small pieces, and throw into the jar. Let them soak for a day or two, then take out and thoroughly dry, and it is ready for use. Try it, and see how you like it.

EMMA WILSON.
Marengo, Ill., Nov., 1890.

Perhaps I should introduce our friend who writes the above valuable article as Dr. Miller's assistant, his sister-in-law. The saltpeter wood mentioned above was given in our journals a good while ago, but I am afraid only a few of our bee-keepers have been providing themselves with it. It certainly is a very great aid in starting a fire quickly. It seems to me, friend Emma, it is a little surprising that the smoker you speak of sustained injury because the doctor stepped on it; and, by the way, is that the way he is in the habit of tramping around over things when he gets in a hurry? Your suggestion of hard-wood turned shavings for fuel is also a good idea. I was intending to write this up after my visit at your place, but I fear I forgot it.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

QUESTION 173. *Taking a series of years, will a colony do better to have its brood-nest contracted at harvest time, or to remain without contraction the year round?*

I do not know.

Illinois. N. W. C.

MRS. L. HARRISON.

We never contract the brood-nest at any time.

Wisconsin. S. W.

E. FRANCE.

With the average bee-keeper, without contraction.

Ohio. N. W.

H. R. BOARDMAN.

Much depends upon the bee-keeper. Contraction, when wisely practiced, is best.

Michigan. C.

A. J. COOK.

We never contract the brood-nest at harvest time. It does not pay. We contract a little in the fall and in the spring.

Illinois. N. W.

DADANT & SON.

"Do better" at what? If for quantity of honey stored, contract, unless the "harvest time" is protracted.

Ohio. N. W.

A. B. MASON.

For extracted honey I would say, do not contract the brood-nest except, possibly, for 30 days in the last part of the main honey-flow.

California. S.

R. WILKIN.

I rarely contract the brood-nest, except in case of weak colonies in spring, and when hiving a new swarm.

New York. C.

G. M. DOOLITTLE.

We have practiced contraction for a good many years, and believe a little of it is a good thing. Too much is worse than none.

New York. C. P. H. ELWOOD.

I do not know. As a rule, I do not think there is much advantage in contraction, except for newly hived swarms. Then it pays.

Illinois. N. C. J. A. GREEN.

It would require more experiments than I have made to give my answer much value. My opinion and practice favor a small brood-chamber not contracted when surplus begins.

Ohio. N. W. E. E. HASTY.

If one wishes to secure all the white honey in sections, it can be more readily done by contracting. I would advise contracting as much as possible for winter.

Vermont. N. W. A. E. MANUM.

Taking a series of years, or one year, I am very firm in the belief that the contraction of the brood-chamber at the right time in the honey-harvest is the most profitable manipulation a comb-honey producer ever did.

Michigan. S. W. JAMES HEDDON.

Contraction of the brood-nest is good only in early spring, for the purpose of making the bees breed up. It is advisable at no other time of the year, excepting, perhaps, for safe wintering, if the colony is weak in the fall.

Ohio. S. W. C. F. MUTH.

I don't know. For a single year more honey can be thrown into a super (theoretically at least) by contracting; but when you say "a series of years," that may alter the case. My observations of late years have made me less sure that contraction has any value.

Illinois. N. C. C. MILLER.

In running for extracted honey I leave the brood-nest the same size the year round; for as long as there is any prospect of honey to be gathered, I want plenty of bees to gather it; and when the honey fails, the bees will do their own contracting as far as brood-rearing.

Wisconsin. S. W. S. I. FREEBORN.

At present we are opposed to contraction. It induces swarming. When running for comb honey it leaves the brood-chamber bare of honey for winter stores. In our out-apiary run for extracted honey, contraction caused swarming in nearly every instance, while hives left with no restriction to the queen did not swarm. We do not believe in close contraction.

New York. E. RAMBLER.

The above reports seem to indicate pretty clearly that contracting about or just before the harvest time is not so much practiced now as it used to be when most of the readers of GLEANINGS had only a few colonies, and could look at every colony night and morning, to see when it needed more room. Our friend Dean, formerly of River Styx, near here, used to be one of the champions in this line; and for building up colonies it certainly worked wonders so far as crowding the bees and the honey into surplus-receptacles was concerned. The recent demand for eight-frame instead of ten-frame hives seems to be in line with the idea.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

N. A. B. K. A.: HOW TO PROVIDE FOR PERMANENT FUNDS: A GOOD SUGGESTION.

Friend Root:—As you said at the Keokuk meeting, that you would undertake to get twenty or thirty life-members to the association, and as we must try to manage to save a certain capital for the association, I suggest that we make it a point to have the funds thus gathered invested in some safe interest-bearing investment, the interest only to be used by the association. In this way we can perpetuate the good work and create an interest. I would even go further; for, as the yearly subscribers are usually sufficiently numerous to pay annual expenses, it seems to me we ought to set aside also the affiliation fees of the State, Territorial, and local associations. In a few years we should have a capital large enough to enable us to offer prizes and premiums for competition, and we should raise an interest much greater than formerly in our meetings. Would you be so kind as to take the matter in hand, and discuss it in GLEANINGS? We must do something to get out of the old rut.

C. P. DADANT.
Hamilton, Ill., Nov. 7.

All right, Secretary Dadant. We will back you in all your suggestions as far as we can. Now, then, who among the readers of GLEANINGS is willing to pay up and stand by us in the effort to make the North American Bee-keepers' Association a permanent institution? It will cost you \$10.00, it is true; but after that you can attend the convention for forty years, if you live so long, and not pay any thing. I have in mind quite a few of our readers who, I think, might, could, and should stand up. Let us hear from you. Who will be first? So far as I know, the editor of the *American Bee Journal*, and Ernest and myself, are at present the only life-members. Who will stand with us?

TO THOSE CONTEMPLATING GOING TO THE ALFALFA FIELDS.

Friend Root:—There is some inquiry in GLEANINGS about whether it would be profitable to move bees to the alfalfa fields of the Southwest. I would not advise it on that source alone. I had two years of experience in Utah, in the Great Salt Lake Valley. I had at one time 44 colonies, and I do not think I ever got any honey from the hay-fields, although there were hundreds of acres near. Where it is raised for hay it is cut as soon as it gets in full bloom, and before it secretes any honey. Where it is raised extensively for seed it is different, and one may usually depend on a fair yield. It is of excellent flavor, but a little inferior to sweet clover. Sweet clover grows promiscuously all over the Salt Lake Valley, wherever there is moisture enough for it to get a start, and I think that is what makes Utah honey the finest flavored in the world.

A. MCCAY.
Olympia, Wash., Nov. 15.

WILL FREEZING HURT FOUNDATION?

Where foundation is kept dry, will freezing, light, or air, injure it in any way for use next year?

JAS. A. ADAMS.
Grimm City, Mo., Nov. 10.

Friend A., the freezing will do no harm at all, providing some inconsiderate person does not

attempt to handle it while it is cold. I do not know of any thing that vexes me much more than to see people who have had experience enough to know better, undertake to move a lot of foundation when it is almost icy cold. Of course, it flies to pieces like thin glass; and then after they have done a lot of mischief they sometimes undertake to repair it, and in so doing they break a lot more of it. Never touch foundation, nor even hardly look at it, when it is in a cold room. Air and light have the effect of bleaching and hardening thin foundation; and as this makes it a little more difficult for the bees to work, it is generally considered better to have your foundation shut up in a box, protected from air and light as much as possible during the winter time.

BOTTOM VENTILATION, AND THE TOP SEALED TIGHT.

Some five years ago I commenced to experiment along this line. The family carriage having received a new top, I utilized the old leather by using it instead of burlap to cover the brood-nest, cutting it to fit on all sides neatly, using this on four colonies, two strong and two weak, using burlap on all others. The leather was laid flat on the frames. They all came through without loss; but those with leather for covering built up much earlier in the spring, and were ready for sections in advance of those covered with porous material. These results being nearly uniform for four seasons, I am this fall using either leather, rubber cloth, or oil cloth double, first laying three half-inch strips reaching across four frames, then this covering pressed down neatly; over this, six to eight sheets of newspaper, then the chaff cushions. This is my plan, with the entire apiary of 25 stands. I leave the entire entrance open (Simplicity entrance), and shall expect good results.

Guys, Md., Nov. 13.

WM. S. ADAMS.

Friend A., your leather is, to a certain extent, porous. I know by experience that it is not to be compared with rubber. My feet rebel at once against any kind of rubber casing; but I can wear dry leather boots very well, unless the weather is quite hot. In hot weather they (my feet) insist on cloth shoes, and will not be quieted with any thing else. I should think that leather would be a splendid cover for bees, if it can be had at reasonable prices.

ONE OF THE CACTI.

I send you a flower by mail. It seems to be a honey-plant as well as a beautiful one. The honey was running out of it when I got it. They tell me that every flower had drops of nectar. Will you please name it, and tell where its native place is?

J. M. KINZIE.

Rochester, Mich., Nov. 10.

Prof. Cook replies as follows:

The flower above is one of the cacti. It is a large, brilliantly colored, bright scarlet blossom, and forms a strange contrast with the leafless stem that bears it. These plants come from the arid, sandy regions of Arizona, Southern California, and Mexico. I am glad that they are honey-plants. It is reported that our "jack-pine plains" of Northern Michigan are localities where bees do exceedingly well. It is more than possible that the strange cactus regions of Arizona may be worthy a similar repu-

tation. Who will inform us in the matter? It is worthy of remark, that the wonderfully beautiful "night-blooming cereus" is also a cactus. Its blossom is large, white, and exceedingly beautiful.

A. J. COOK.

Agricultural College, Mich., Nov. 15.

KEROSENE TO KEEP BEES AWAY FROM WATERING-TROUGHS.

I use a kerosene-barrel for watering stock, and am not troubled with bees. I provide a suitable place for the bees to drink, and pump fresh water in their trough every morning. The secret of it is, bees dislike kerosene oil nearly as bad as our editor dislikes tobacco.

Eau Claire, Wis., Oct. 25. C. B. JACKSON.

Thank you, friend J., for the compliment. If you have a kerosene-barrel, of course you have the smell of kerosene always around your watering-trough. The idea is a good one. It now occurs to me that we used half a kerosene-barrel for many years for watering our cow, and I have never seen a bee near it.

WHEN TO MOVE BEES A SHORT DISTANCE; LICE ON IMPORTED BEES.

I have 16 chaff hives in the garden, around the fence. I should like to move them about 125 feet, where the rest of the apiary is. Can it be done without any loss of bees? If so, when and how?

My friend C. received from Italy a short time ago a queen and attending bees that had red lice on them, or something that looked like a wood-tick. The lice were sticking on their shoulders and under their wings. The abdomen of the tick was short and round, and a brownish red color. What are they, and are they injurious to the bees?

JESSE MCNEELY.

Putan, Pa., Nov. 8.

When the weather turns cold, move the bees where you want them. After bees have been confined a few weeks they will readily return to their new location. The lice you speak of are often found on imported Italians, particularly on the queens. In fact, we rarely have an importation without seeing some of them. They are called the Italian bee-louse. They do no real harm, although we always remove them from the queens.

LONG FLIGHT OF BEES; IS IT TRUE?

This strip of paper states that bees fly 14 miles. Do you think it is so?

F. TOMPKINS.

Lawsville Center, Pa., Nov. 10.

The following is the clipping referred to:

INSTINCT OF BEES AND ANTS.

How insects, especially bees and ants, find their way back home is one of the marvels of natural history, says a farmer in the St. Louis *Globe-Democrat*. My wife keeps bees, and my little boy has a taste for entomology, and is always making experiments of one kind or another with them or other insects. He has been trying to find out how far away a bee can be taken and not get lost, but has not yet succeeded. I live in the country, fourteen miles from the courthouse, and during the summer that boy has been in town with me a dozen times, and on each occasion he brought some bees along in a little tin box. He colored their wings with violet ink, so that he would know the insects again, and let them go in the heart of the city. The first time he did it he released six bees at the Biddle Street market, and I believe they got home before we did, because they were all on hand attending to business the next morning, just as though they took a fourteen-mile journey every day. Occasionally a bee fails to come back, but in nearly every instance they return in a few hours. Once

he let five, whose wings had been colored red, out of their box at six o'clock in the morning, on the corner of Fourth and Biddle Streets, while his little sister watched the hives at home. One arrived, tired almost to death, and dropped at the door of the hive a little before two o'clock, and three more came before five o'clock in the evening, all apparently much fatigued. His experiments with a nest of large black ants have been equally satisfactory, for some marked ants have found their way home, after being released, more than a mile distant from the hollow tree in which they lived. How they do it is a question, but they generally do, and so it is likely the travels of both ants and bees are much wider than is generally supposed.

Friend T., I feel quite sure that the above extract is not true. It seems to me strange that our newspapers will get hold of such false statements, when careful facts from careful observers are scattered all through our bee-journals. Perhaps it might be well to hunt up that boy and see whether any such experiments were ever really made. The most reliable experiments that we ever made in this line, I believe, were made by our friend H. A. March, of Fidalgo, Washington.

WHAT KIND OF BEES ARE THEY?

They are very yellow below their shoulders, but their head and shoulders are black, not quite as large as Italians, and splendid robbers.

Ernest's notes are very interesting, also many other things in GLEANINGS. Almost every number brings items worth many times the subscription price.

A. P. FLETCHER.

Proctorsville, Vt., Nov. 8, 1890.

It is hard to tell, from your description, what the bees are. The fact that those mentioned have very black shoulders (thorax) leads us to believe that they are old Italian bees that are tired of honest toil, such bees having learned that stealing sweets is faster and apparently more profitable. These wear the fuzz off their shoulders in crawling through holes and narrow crevices to steal. Young Italians are not given to robbing, and it is only the old bees that have learned the trick, usually.

AN APIARY OF BLACKS AND ITALIANS: THE LATTER SECURED 30 LBS. PER COLONY, AND THE FORMER NONE.

I see a great deal said about the Italians. They are the best with me. I have 38 colonies: 18 of them are black, or nearly so. I did not get a single pound of surplus from the blacks; but from the 20 Italians I took 600 lbs., or 30 lbs. per colony, of nice honey, and left them in as good or better condition than the blacks. I am going to put Italian queens in all of them next spring. The past season was very bad for honey, so we sold all of ours as fast as we took it out. I have bought 480 lbs., and I shall have to buy more if I keep it for my customers.

J. F. TEEL.

Elmont, Texas, Nov. 8.

A DEMAND IN CALIFORNIA FOR PERFORATED ZINC AND A REVERSIBLE HONEY-EXTRACTOR.

There will probably be a demand for queen-excluders in California until all apiaries are supplied, and a good strong reversible honey-extractor should sell well. I have seen extractors in this county that cost \$50.00 each, and were not well made either. I shall be pleased to receive a sample of your new perforated zinc.

Fillmore, Cal., Oct. 27.

J. F. MCINTYRE.

BEES AND NEIGHBORS.

I am a poor man, and have a lot of $3\frac{1}{2}$ acres, and am crippled at that. I had my right foot amputated about a year ago. I am in debt quite a bit. I once thought I couldn't get through. Alas! a kind friend lent me money and took a mortgage of \$180, and gave me good time; and if I can only keep up the interest, all well. This is a great help for me. If I can only live and support my family, which are three besides myself, and pay my interest, I am well satisfied. I then took a notion to go into the bee business, so I got 23 good colonies, and I should like to have about 100 in all, then I could get along well. I can't work by the day. Hands are plentiful without a cripple, to work by the day. Now, the question is this: Can a neighbor do any damage to me by the law for keeping so many bees? My bee-yard is about 10 rods from his dwelling. He says they will hurt the grapes. Now, what shall I do? I surely can't keep them away. Our nearest town is Middlebury. We live three miles from it, but there are three lots here close together. The other is owned by an old widow woman. She won't say any thing. How far away should my bee-yard be from the highway? It is at present about six rods from the public highway. My bee-yard joins his lot.

EDWARD GEGAR.

Middlebury, Ind., Nov. 10.

If it were not for the general prejudice of ignorant people, your bees would do well enough where they are. On the whole, we would move them to the back yard; or, at least, a hundred feet from the street. Bees will not injure sound grapes; but they will attack those injured by birds or insects. Still, even this amounts to but very little. We have for years kept bees, and had grapes growing in the same yard, and we have little or no trouble. If you explain the matter kindly to your neighbor, occasionally presenting him with a nice section or jar of honey, he will let the matter pass. In view of your misfortune he ought to be a little lenient, any way. If he should be ugly, you can have the aid of the Bee-Keepers' Union, providing you are a member. Thos. G. Newman, of 246 East Madison St., Chicago, is the General Manager.

HAS BEE CULTURE BEEN INJURED BY THE USE OF PARIS GREEN, ETC.

I returned from Michigan a few days since, after a good visit with my people, and particularly with my brother, who keeps bees. He was very enthusiastic on the subject of bees—in fact, so enthusiastic that I brought a five-frame swarm all the way in my hands. I have a cotton plantation, and believe I could buy a few bees, and, with proper study, I could make it profitable. I had previously heard of marvelous yields of honey in this locality, but I was not personally acquainted with any of the bee-keepers. I find, upon partial investigation, that this has been a favored location, but that all have become discouraged, and are anxious to sell out. They say that, since the use of Paris green for killing cotton-worms has become general, their bees are killed, and all chances of profit destroyed. Have you, in any number of GLEANINGS, or elsewhere, any thing to throw light on the subject? I do not want to give up the bee enterprise if there is any way to get around the poison question.

W. H. BRISTOL.

Shreveport, La., Nov. 7.

Friend B., I do not think the bees have suf-

ferred very much from the cause you mention. There was some apprehension about Paris green when it was first used; but, so far as we have been able to learn, lack of attention has very much more to do with it than any injury resulting from poisons used to kill insect enemies. Of course, we don't know how it may be in your neighborhood; but if you look into the matter carefully, we think it will be as we state.

HOW TO MAKE A WATERING-PLACE FOR BEES.

I use a ten-gallon keg; bore a hole near the bottom, put in a faucet, then take a soft pine board about 2 ft. long, and with a hatchet I hack it all over on one side to make it as rough as possible. Set the keg on a block (a box will do) about 18 inches high. Now place one end of the board just beneath the faucet, and the other end in a very small trough. Fill up the keg; cover it well, so that no bees may fall in; turn the faucet so that it will drip just to suit. With this arrangement near they do not trouble me much in the watering-trough, except on a very hot day, when a little coal oil rubbed in the trough just above the water will keep them away. They will not go into a trough that is painted with coal tar inside.

Our honey season is over, with an average of about 30 lbs. per colony. Bees did fairly well, considering the dry season. Ed. E. SMITH.

Carpenter, Ill., Nov. 7.

Thank you, friend S., for your excellent suggestion in regard to a watering-place.

AN OUTSIDE CASE FOR WINTERING.

I see several inquiries in reference to outside winter cases for the Simplicity and Dovetailed hives. For this winter I have packed all my single-walled hives by making a case, out of rough inch hemlock lumber, the top of which is first covered with boards from old glass-boxes; then a covering of heavy manilla paper, well tacked, and coated with two or three coats of good thick paint. The case is made large enough to allow putting old newspapers or heavy paper over the hive when it is dropped down over. As the hives are 10 inches deep, I made a cover of ten-inch stuff. This made a good winter double-walled hive, and I think it will be as good to winter in as chaff hives. I have packed 30 colonies so this fall, and will report success. For the first time in years I had to feed ten or twelve colonies; but with a modified Miller feeder it was little trouble, as I could feed from 10 to 15 lbs. in 24 hours.

T. G. ASHMEAD.

Williamson, N. Y., Nov. 10, 1890.

BEE-STINGS FOR RHEUMATISM: A PHYSICIAN'S STATEMENT BEFORE THE FRENCH ENTOMOLOGICAL SOCIETY.

Dr. Al. Labourene, at the meeting of the French Entomological Society, held on March 13, 1889, gave a short abstract of a paper published in 1888 by an Austrian physician, Dr. Terc, who seems to have made extended experiments for a number of years. Dr. Terc asserts that a person stung by bees acquires thereby a relative immunity from the consequences of subsequent stings; in other words, that the virus of the bee-sting acts like a vaccinal inoculation against its own poison. The immunity lasts about six months, sometimes less, probably according to the number of stings inflicted on a person. Persons suffering from acute rheumatism require a larger number of bee-stings to feel the usual effect of the poison; but as soon as, by inoculation of a sufficient amount

of virus, they have acquired immunity against its effect, they will be free from rheumatic attacks as long as this immunity lasts.

A. J. BLANKINSHIP.

Eldorado, Ills., Nov. 16.

TWO DIVISION-BOARDS.

I notice what Mr. H. L. Jeffrey (pp. 771, 772) has to say regarding two division-boards. I deem the subject of very great importance to us bee-keepers. I have used two division-boards and paper packing, for many years, with the very best results. For beginners, your advice in the A B C, if I remember well, must be followed. Get your bees in good trim for winter in time—in this part of the country, say the middle of October. The bees need time to fix up for winter. Gluing, patching, etc., must be done; and for all this, give your bees plenty of time in fall. The less you handle your bees in fall, the better for them.

The Dovetailed hive, with closed-end frames, is still the very thing many of us looked for.

HOW BEES MAY BE INDUCED TO WORK IN SECTIONS.

During a good honey-flow, remove the queen from one of your best colonies. Also remove or destroy all queen-cells. In a day or two, give to this queenless colony a hive with nothing but section frames, save one, which will be a brood-frame with queen-cells just started. The other brood-frames from the parent hive may be given to any populous colony for a few days. Then with the hatched young bees, strengthen the queenless colony as much as possible; and before a young queen appears, sections are filled.

I must thank you once more for the fine select tested queen you kindly furnished me last July. If one man owns a \$100 queen in our country, I say fifty dollars can not buy my Aurea—thus I named her, on account of all rare qualities combined and possessed by her.

REV. P. STEPHEN STENGER.

St. Meinrad, Ind., Nov. 10.

THICK TOP-FRAMES A SUCCESS.

Last fall I had 32 stands of bees in the thin L. frames; and wishing to have the best for preventing brace-combs I studied all that was said in GLEANINGS respecting them, and came to the conclusion I would make my frame top-bars 1 inch wide and $\frac{3}{4}$ deep. So I made 45 hives, dovetail pattern all but the dovetail, and slatted honey-boards, and made them enough deeper to suit the heavy frames. As it was a poor season I did not need many surplus cases on; but what I put on, on the new heavy frames, did not have any brace-combs above the frames; but where they were spaced a little wide there were some odd bits of comb from one to the other, but none above the top corner of the frames. Then, again, where some were spaced rather closer there were no braces anywhere. Again, by changing hives and swarming artificially two or three, and raising a few queens from my best stocks, I managed to get the thick and thin top-bars in the same hives. One in particular was like this: Two of the heavy thick frames, then one metal-cornered frame; then two more thick ones, then another metal-cornered one; and, last, two more of the heavy frames, and now there is not a particle of brace-comb on the thick top-bars, except where they come next to the metal-cornered ones, and then the thick ones are braced fast to the metal-cornered ones, and are also built right up and fast to the slatted honey-board. You see those were the only places where brace-combs were built right from the two metal-cornered ones.

JOHN HAMMOND.

Buena Vista, O., Oct. 24, 1890.

MYSELF AND MY NEIGHBORS.

Then one of the twelve, called Judas Iscariot, went unto the chief priests, and said unto them, What will ye give me, and I will deliver him unto you? And they covenanted with him for thirty pieces of silver. And from that time he sought opportunity to betray him. MATT. 26: 14-16.

Judas betrayed his master, Christ Jesus, the Son of God, for thirty pieces of silver. Was he crazy, or was he a fool? One can hardly believe that pure rascality or depravity, or selfish greed, should ever prompt any human being to such an awful piece of hypocrisy and treachery, especially for such an insignificant sum of money. How *could* Judas have ever been in such a strait or in such need of a little money as to go into such an *awful* speculation as the one narrated above? Mankind has for all ages stood aghast at the fearful inconsistency and folly of this shameful deed, especially when he by a *kiss* indicated to his enemies which was the Master. We are tempted to say that he could not have been in his right mind. The poor fellow must have been a monomaniac; and yet we read nothing of the sort in the Scriptures. God's holy book simply gives it as an illustration of sin in the human heart, and Judas is held up before us as a warning. In one sense, Judas *was* crazy; but isn't any man crazy in the same way, who barter his good name and his chance of future happiness for a few paltry pieces of silver? Cherished sin makes *anybody* crazy. He loses his ordinary good sense, and he becomes incapable of exercising ordinary judgment.

A great many excuses have been made for Judas, such as, that his faith in his Master was so great that he believed he would deliver himself by some wonderful miracle, and the result would only be for the general good. A good many people, since the time of Judas, have decided to do evil, and have excused themselves by saying that they *thought* good would surely be the outcome of it.

Well, what have bee-keepers and honey-dealers to do with Judas and his thirty pieces of silver? It has occurred to me this morning that many of us have something to do with Judas' inconsistency. We see a chance to get some money, and we push ahead to get it in our hands, with a foolish, shortsighted disregard of consequences. We barter our good name for a *few pieces of silver*. I do not know but I had better put it stronger than to say *we*, and come right down to the point, and say that sometimes it looks very much as if *A. I. Root* had been tempted to barter his good name for a few pieces of money. I want to make a plea for mercy, though, right here. Dear friends, you do not know what an awful busy life mine is. I am too *busy* to do *justly*, but God knows I do love "mercy;" and I am sure I try, about as well as a busy man can try, to "walk humbly before God."

You may, perhaps, say that I have no *business* in having so much "*business*." Well, that is true; and that is the worst thing I am guilty of. And I do not know but it is a pretty bad sign to have so much business that you can not see that it is all attended to as *honestly* as it should be. I will tell you how it is. I have been working very hard during the past fall. For some weeks I have not had any fun in the garden, hardly, because there are so many things to be looked after, and arranged and decided on. I have not even had the fun of studying over greenhouses—the new kind, you know, that is to be a *garden* when it rains and the sun is warm, and to be a *greenhouse* whenever every thing is frozen up solid. It is true, I have been

dreaming of this new greenhouse nights, after going to bed, and at other times when I do not "have to" do something. Yes, I say to my shame, that my truant mind sometimes gets away on Sundays, even during sermons, and plans this new greenhouse, instead of listening to our good pastor. I have felt bad about it, and prayed over it; but the plans would keep working themselves out. And now during this fine weather in November I have been trying to get time to instruct workmen how to build it *after* the plans have been so long working and evolving in my busy brain. As a consequence, things have been somewhat neglected. Some days I feel as if I had no business in thinking about greenhouses at all—that I had better let well enough alone, and "stick to my knitting"—the journal, factory, etc. Why, I told Mrs. Root, only last summer, that, if my *present* frame of mind did not change, I would give up gardening. I fear it changed in about two or three hours. Overwork in the office pulled me back to my old nervous prostration, and then it began to be a question, "Should I enjoy myself out in the open air, with growing plants, and *live*, or stay in the office and defend my good name before the children of men, and *die*?" None of you need be worried, dear friends. I am going to live, and enjoy God's gifts outdoors, just as long as I can. If I can not do any better, when somebody says he has been wronged I will ask him how much money it will take to make it right, and fix it that way, without going into details. Some of the friends have, however, "got awful mad" because I suggested such a way of defending my good name. Two or three have declared that *money* would not do it, and I am afraid they are pretty nearly right, after all. Let me give you a sample of some of the burdens that oppress me just now. Please read the following letter:

A. I. Root—Dear Friend:—While it is an unpleasant task, yet I feel it my duty to write to you. This fall I bought of you alfalfa and mesquite honey to the amount of *one hundred and twenty four* dollars and some cents' worth. I asked you to do the best you could in the way of rates. After waiting a long time after I got the bill, the honey came, with, I think, \$8.00 freight on it. It had been billed at local rates all the way, making three different billings. I wrote you about it, and got an answer which seemed to me quite short and indifferent. In this letter you say you had asked for rates; and as soon as you got them you would make it right with me, or words to that effect; but I have never heard from it yet. I afterward sent you an order for more honey, which came to *hand* all right, but it is awful stuff to call honey. It is about as dark as a low grade of New Orleans molasses—nothing whatever like the sample sent me. I sold some of it, and had some of it refused and returned. I will inclose some of the answers I got from the parties whom I sold it to. These letters are from neighboring towns where I sold it, where I had sold my own honey; the rest of it I sold in our own town; and I never did any thing in my life that has been so unsatisfactory. I would not for *one hundred dollars* have my reputation injured as this honey has done.

While I do not want to accuse you of willfully selling honey of this kind after praising it up as you have done through GLEANINGS, yet I think some one is grossly at fault for selling such honey and branding it first class. I do not ask you to take my word for it. If you doubt my word, I will send you a sample of it, and you can then see for yourself.

Very resp'y. G. B. SHELTON.

Brownsville, Pa., Nov. 21.

P. S.—After reading Our Homes these many years, and longing for them to come, and feeling that I know you personally, I do not think that you would allow this thing to go on if you knew it. G. B. S.

Below are the letters our good friend Shelton refers to, omitting addresses, for obvious reasons.

MR. G. B. SHELTON:—I return above, being very dark and unsatisfactory. I could use good honey like last year's, but not this kind. J. K. B.

MR. G. B. SHELTON:—Your honey at hand, and we find by proper test that it is not satisfactory in regard to flavor, and will ask if you want it returned, as we can not use it.
(Uniontown, Pa., Oct. 10, 1899.)

M. & B.

MR. GEORGE B. SHELTON:—The honey arrived safely, and I would have replied earlier, but have been away a day or two, and been quite busy also. I am sorry to say that I do not like the honey as well as what I have formerly had from you, nor do my friends like it. It seems to have a taste and smell like tobacco—that is the only thing that I can liken it to. What is the matter with it?
E. A. J.
□ Charlevoix, Pa., Oct. 10, 1899.

□ Friend S., I want to thank you, to commence with, for your concluding postscript. Even if you have been misused, and have suffered, it indicates that you feel *neighborly*; and my experience indicates very strongly, that, if a man wants to be treated in a *neighborly* way, he must *commence* in a neighborly way. While we do not agree to be responsible for mistakes that railroads make, we certainly do not mean to be indifferent to the interests of our customers. As we understand it, your honey passed over three different railroads. This, of course, would add much to its charge. While every shipper should be prepared to do his best in deciding upon the cheapest route by which to send goods, as a general thing the one who orders the goods can tell better the best route to have them shipped. As a rule our customers do indicate the route. Sometimes they tell us if we think we can make a better route, to do so; but it requires a man of large geographical knowledge and experience, and one who keeps constantly posted in regard to the railroad lines, to be able to help in this matter intelligently. We are already provided with guides and books, and every thing else that can help us in this matter of transportation, and we are still working hard for better facilities and more knowledge. I have often remonstrated with the clerks because of the brevity of their letters, and a seeming lack of interest in the needs of our customers. But they often tell me, that, to write at length, as I do, would take so much time that it is entirely out of the question; and as evidence of the truthfulness of their standpoint they might point to great heaps of letters on my desk, to be answered if I ever get time to do it. I do wish, from the bottom of my heart, that it were possible for me to look up every tangle in business, and answer it at length; but I fear, dear friends, you will have to accept the will for the deed for a good part of it. Now comes the real trouble. Our friend probably asked for a sample of the Arizona honey, and we sent, as we supposed, honest samples. In that carload from Arizona there were something like 500 sixty-pound cans of honey, nailed up two in a box. The association that shipped the honey received it from ten or twelve different individuals. These individuals graded it themselves, and marked the grade and quality on the outside of the boxes. When we first received it we opened quite a large number of cans, and the grading seemed to be so honest and square that we accepted the labels on the outside, without going to the tremendous task of opening every one of these 250 boxes and sampling the honey. It turned out afterward, however, that we should have saved a deal of trouble by doing just that very thing. Somebody among the ten or twelve shippers was either lacking in conscience, or else was so heedless that his offense was about as bad. This is nothing very strange. You can hardly go into any community and find ten or a dozen bee-keepers, or even farmers, who would not, if they had a chance, work off a poor grade of their product so as to get a high-grade price for it. In fact, almost *all* of us have done more or less of this kind of work until we learned by experience that it would not do. Oh that I could impress upon the minds of the readers of GLEANINGS the fact that honesty *is* the best

policy! We need men now in this present age—and, oh there is such a *sad* need of them!—who will put up any thing for market in such a way that a commission man or the purchaser who gets them will know from the *character of the man* that there is no need of breaking open packages to see if they are honest throughout. Friend Terry has built up his reputation, not only on potatoes, but also on strawberries, by this kind of honesty; and he has been exhorting the whole nation, through his writings, and through his institute work, to do just this very thing. Dear friends, just think of it! Friend Shelton says he would not have had his reputation injured as it has been, for a *hundred dollars*, and no doubt he is pretty nearly right about it. This damage must be made good by some one—that is, some satisfactory arrangement must be made with these customers. If the man who shipped poor-grade honey will not do it, it falls upon *us*. It is like the story I told a few weeks ago, about writing Breckenridge County for Bracken County, only that was an innocent blunder, perhaps, and this is the consequence—at least it would seem so—of a *deliberate* attempt to defraud.

We are now coming to something that cuts close. Friend S., we want you to tell us what initials were on those boxes of bad honey. And, by the way, I think the time is coming when every package of honey must have the address on it of the producer, and the producer must stand responsible for the truthfulness of the label outside. To do this is going to make a good deal of trouble in raking up these transactions; and especially getting them into print is going to hurt somebody's feelings terribly, perhaps. But it is the only true and sure foundation upon which to build up a great trade in our industry. This great trade has already got a good start, and people are getting to have confidence; and we as bee-keepers must *fight* for this confidence, and must fight for our integrity, as we would fight for the American flag.* It is the only solid rock on which any industry can be built up. The butter and cheese business have had to go through just this kind of work, and they are going through it now, and it is the same way with those who produce and handle eggs. There is no way but the honest way. The patriarch Job say:

"As God liveth, who hath taken away my judgment; and the Almighty who hath vexed my soul; all the while my breath is in me, and the spirit of God is in my nostrils, *my lips shall not speak wickedness, nor my tongue utter deceit.*"—(Job 27:2-4.)

The italics in the above text are my own; and the only course for us is to rise up in our strength and in our might, and say with good old Job, "My lips shall not speak wickedness, nor my tongue utter deceit," not even though bags of money that we sadly need are held out as a bribe for just a little bit of deception.

□ We will try to give the outcome of our settlement with friend S., in a later number.

Now, dear friends, it is not the extracted-honey men who are guilty. The same kind of work comes up more or less in crating comb honey. Very likely it is carelessness, or setting somebody to work to help pack the honey who does not know any better than to put nice clean white sections on the *outside*, and the dark ones *inside*. Here are some letters below that tell you how it works in our great cities:

*A verse of my favorite hymn occurs to me here:

Are there no foes for me to face!
Must I not stem the flood!
Is this vile world a friend to grace,
To help me on to God?

The first one was received with check for honey sold on commission.

Mr. Root:—We hand you herewith check covering sales of your last shipment of honey to us. We had bad luck with part of it. We made shipment to the country of a lot, and it was refused on account of being black. We ordered it returned. In the trip it was badly broken up, and we sustained heavy loss on it from leakage and waste. This last end was what kept us waiting so long. We are now in good shape to handle another shipment for you. One-pound sections are the kind that sell best.

REYNOLDS & WILLIAMS.

Cleveland, O., Nov. 19, 1890.

The above lot of honey was a part of the carload received from friend Ball. As it looked very nice when taken from the car, and seemed to be in excellent order, therefore we were greatly astonished, and wrote immediately to know what the commission men meant by calling it "black." I confess that we were somewhat *stirred up* about it, as a great part of the carload had already been sold at good prices, and no complaints. The letter below explains:

Mr. Root:—We are very sorry to have you feel as your letter indicates in regard to the honey receipts and report of sales. The writer saw the honey that was returned, and it was black on the inside sections while the outer ones were clear and white. We had several shipments returned which delayed remittance, and the causes for returning to us were just, as the honey was as we have stated.

Cleveland, O., Nov. 21. REYNOLDS & WILLIAMS.

There you have it, friends. From what I know of friend Ball I can not believe that he *himself* put up his honey, or knew that it was put up with unsightly sections *inside* and the nice white ones *outside*; and I confess that I was quite loth to believe that he had intrusted anybody with packing it for him that would do such a thing. In all great markets it is well known that the man who packs his produce so as to make it show well on the outside, while inside it is poor and unsightly, it sure to get a wide berth on any future shipments. It *kills* any man's reputation. You remember what Jesus said about the scribes and Pharisees:

"Ye make clean the outside of the cup and of the platter, but within they are full of extortion and excess."

In fact, I had looked at the honey, and had seen several cases opened, and had taken great comfort in thinking that we had a *whole carload* that was just as good *clear through* as it was outside. But I at once hastened to our men who put the honey up for shipment, and something like the following conversation occurred:

"Mr. W., how many cases of that carload of comb honey have you *overhauled* so as to get a look at the *inside* sections as well as the *outside* ones?"

"Oh! quite a few—I don't know exactly how many. Where a case was leaking a little we overhauled it and got out the broken section and put a sound one in its place."

"Well, did you find any cases of honey that were dark and bad looking inside, with the outside sections clean and white?"

"Yes, there were some put up in just that way, and I showed it to Mr. C., and he replied that the dark appearance was only the result of leaving it too long on the hive—that the *quality* was just as good as the other, and he thought it would not be necessary to go to the trouble of overhauling and repacking."

So the commission man was right, after all—at least, our honey *was* open to the charge that the best sections were put on the outside. Mr. C. said afterward that this was not the case with a great many, certainly, for he saw badly stained sections right out against the glass, indicating that the packer put at least *some* of them in just as they happened to come.

Now, a great many think this is a small matter, any way. But I tell you, it is a matter of *tremendous* import to honey-producer and honey-dealer. The thing has come up so many times that our grocers are sore and sensitive; and just as soon as they begin to open a package of goods, and find it put up with the best *outside*, they get indignant. Who can blame them? Had this dark or stained honey been put by itself, and sold at what it would bring, it would have saved condemning, and selling at a low figure, perhaps quite a quantity of first-class white honey. I know there are some who say that the honey that has been longest on the hive is the best ripened, and is therefore *not* inferior; but when it comes to Thanksgiving, or Christmas, circumstances demand that he who wants something nice-looking should have it. Our daughter Constance has just come home from Oberlin to spend Thanksgiving. Like the average schoolgirl of 18, she has a big appetite for every thing belonging to home, especially for fruits and dainties. On my way home from the union prayer-meeting I stepped in at one of our leading groceries to get something to please "Blue Eyes." As I looked over their display, what sort of goods do you suppose I picked out? Why, like everybody else I wanted something handsome-looking—something that would make the whole household lift up their hands in admiration. Of course, I wanted it good too. But I was ready to pay—shall I say double price?—to have something that looked perfect to the eye. What I mean is, some perfect and faultless specimen of *dame Nature's* handiwork. I paid 20 cents per lb. for some beautiful clusters of white grapes—that is, just a few—etc. Now, dear bee-keeping friends, do you see what the great outside world demands of us, and wants us to do? The beautiful little text, "Thinketh no evil," is making big headway in the hearts of our people; and when we give way to this foolish, selfish longing for the thirty pieces of silver, as Judas did, we are not only killing ourselves spiritually, but we are also killing ourselves *financially*. In fact, we are doing just the thing to spoil for ever any possible chance of getting hold of any *silver* at all; and, besides that, if we are professors of religion we are tempting this great outside world to say, "There, there. Not any more of that, if you please. If that is Christianity, I think I would rather buy my stuff of somebody who does not make any profession." What shall it profit a man if he gain the whole world and lose his own soul? But you see he *does not* gain the world either. The *world* is lost and the *soul* is lost—*every thing* is lost. This is Thanksgiving day, and ten o'clock in the morning. May the Lord help us all to shake off this fearful nightmare of selfishness that seems so bound to settle down upon us unless we are holding fast to the strong arm of Him who went about doing good, and who went through the world and lived a human life, but who came out victorious, a model and a pattern of all that is unselfish. *He* "pleased not himself."

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

GARDENING IN DECEMBER.

It is now the day before Thanksgiving. We have beautiful Grand Rapids lettuce in the open ground, still unharmed by frost. And this reminds me that the *Rural New-Yorker* makes a suggestion that is new to me, and possibly is of considerable value to the market-gardener;

namely, that lettuce, radishes, etc., may be grown nearly to maturity in cold-frames. Just before severe weather comes on, cover them with glass and straw mats, and thus keep them fit for use during a great portion of the winter. This can be done much cheaper than to go to the expense of heating, to grow them in the winter time. I am quite sure, from what experience I have had in the line, that it can be managed. Just now we have a fine crop of beets, from the size of hens' eggs down. They are as yet uninjured by the frost, but will soon be injured without protection. One of our boys suggests that we gather them, cut the tops off, and transplant them to cold-frames or green-houses. A beet is a great thing to start to grow, as you know. When they make nice new tops, sell them off for bunch beets during the winter time.

Cauliflower can, without question, be kept in cold-frames, the same as lettuce. Celery is so commonly kept all through the winter months, even into February and March, that I have hardly thought that any instruction was needed. As so many inquire, however, I will tell you what I know about it.

KEEPING CELERY DURING THE WINTER.

If you have only a little, put it into your cellar in a box without top or bottom. Let this box stand directly on the cellar floor. An earth floor is best. The box may be as long as you choose, but it should not be more than a foot or 18 inches wide. If you get too much celery in one body it is apt to rot. Dig your celery, leaving considerable dirt on the roots. Pull off most of the outside leaves, and pack it in the box as closely as possible. Your cellar should have plenty of doors and windows, so that you can keep the temperature pretty close to freezing. Celery will stand considerable frost in the open ground, but not very much in the cellar. In its winter repository, two things are to be guarded against—rotting and freezing. Rotting is the worst trouble. Keeping it cool, and giving it plenty of air, is the remedy. If your cellar is so dry that the celery is likely to wilt, and get like shoestrings, you may moisten the roots; but do not put any water on the tops. It will make it rot. Sometimes a little cavity is made in the cellar bottom, say two or three inches deep, and water is poured into this cavity. This will keep it growing some if your cellar is not too cold; but if it grows much in the cellar, it is likely to become hollow and stringy. Now, putting up celery on a large scale is just like the above, only, instead of the box, you can set up boards a foot wide and 16 feet long. Keep them up from the cellar bottom by means of pieces of 2x1 scantling laid at right angles with the long boards. This is to let enough air circulate to prevent heating. When you want the celery to blanch—that is, if it is not blanched when you gather it—shut off the light and raise the temperature until the celery is just right for the table. Last winter we had some beautiful celery wintered in a vacated pig-pen. Now, do not smile nor turn up your nose. The pigpen is under shelter, and is a part of our tool-house. We cleaned it out nice and clean, and dug down perhaps a foot below the surface of the ground. After it was packed away as above, between long boards a foot wide, we covered the whole top of the pig-pen with the same kind of one-foot boards, and over these boards we put stable manure enough to keep the frost out. A good deal of dirt adhered to the celery, and the dirt in the bottom of the pig-pen made it so rich that it grew some all winter, especially when the heat of the manure above it raised the temperature enough. The celery, when put away,

was quite green, and not blanched enough for use. The variety is the New Rose. The stalks were a bright rose red when put away. In January the darkness and warmth had bleached it so that it was received by everybody as *white* celery with an occasional rose tint to it; and it was the most crisp and delicious celery I ever tasted in my life. This year we have a cellar under our new factory, about 40x100 feet, and the door is so large that a horse with a mud-boat can draw a load of celery right where it is to be packed between the boards. A low sled or mud-boat is perhaps as handy as anything to draw the celery from the field. Put it right close to the rows, so that the men who pry out the stalks with tile spades can set them right on the boat. A box should be placed on the boat, made of boards, perhaps a foot high. A common stone-boat will do, but it draws rather harder than the right kind of sled.

Celery *can* be wintered outdoors in our locality in average winters; but as it is risky, it is not generally to be recommended. If, however, you think you will want to use it all by Christmas, you can manage it this way: Bank it up clear to the very tips, then make a trough of boards. Invert this over the row, and cover with coarse straw manure. This will keep it till Christmas safely, and many times even till spring. The objection is, the amount of labor required for so small a quantity of celery at the usual distance apart of planting. To save labor you can dig a trench a foot wide, and, say, two feet deep. Put a tile in the bottom of the trench, to make sure that it does not get filled with water. Now pack in your celery, just as before directed, in the cellar. Earth up; put an inverted trough of boards on top to keep off the rain; put on your straw manure, and it will answer about as well as a cellar. The only difficulty is, that you can not very well get at it during very severe weather in the winter. It is much handier, as you will readily see, when stored in the cellar, as first directed; for in this case you can put it on the market very quickly whenever a good price is offered. A combination of the two plans is what is called a "celery-house." This is built anywhere outdoors, where the ground is so thoroughly drained, or stands in such shape that water can not get inside. Dig down two feet, throwing the dirt outside so as to form walls. Put in your celery; cover with any kind of rough cheap boards, or whatever is handiest, leaving just room enough to stand up and go between the rows of celery. Have a thermometer or thermometers hung in different parts of the structure, and go around often with a lantern, and see that the temperature does not get below the freezing-point. If it were not for getting around among the stuff with a lantern, to see how it is keeping, I would have a roof within two feet of the tops of the celery. With such a low structure there is less difficulty in keeping the frost out; and if you are young and small, so you can afford to stoop down and crawl through the avenues, you may make it low. Pack your celery in rows so that you can reach any of it from some one of the paths, to see whether it is freezing or rotting, and put a board as directed, so the rows of celery shall not be much more than a foot from one board to the next. Unless you do this it will fall over and make you trouble. It will pay you to do this work decently and in order; and if you plan it beforehand according to the length of your lumber, there need be no cutting or sawing, and the structure can be put up very quickly. You can make it so as to be permanent, or you can pile your lumber up under shelter during the summer time. If you are going to make a permanent structure, however, I rather think I would have it in the form of a

cellar under some building, providing you have plenty of doors and windows to give it lots of air if it threatens to rot on your hands.

With the cheap structure you can remove the few boards when ventilation is needed; but be sure that your roof, whatever it is, never permits water to drop through on to the tops of your celery; and be sure that you do not leave the ventilator open at any time when rain or snow may get in, for any kind of wet or dampness on the tops when in its winter repository will be sure to make it heat and rot.

In our locality we put away our celery for winter, about Thanksgiving time.

OUR CONDENSED SEED CATALOGUE.

Very few additions will be made to our catalogue of last year. The Breadstone turnip we mentioned in our last issue continues to be a favorite with the wagon. E. C. Green, of the Ohio Experiment Station, says, in our last issue, that he hardly sees how he can get along without the Golden Wax bean. We have found the Kidney Wax to have larger and handsomer pods, and it is much less liable to rust. We shall perhaps be obliged to catalogue a pole bean aside from the limas, and I think we shall use the Dutch Caseknife on the strength of friend Green's recommendation. For the same reason we shall include Crosby's Egyptian beet. We dislike to drop the Golden Self-blanching celery, but our trade this season has given the White Plume the preference. On the strength of friend Green's recommendation we shall use the Spanish King onion (Maule's Prize-taker) for starting onions in the greenhouse. The White Victoria is too poor a keeper. Have the friends at the Experiment Station tried the Breadstone turnip? Fottler's Brunswick cabbage we shall take for a late one. Our friend Jennie Wilson speaks so highly of the Shoepeg corn that I am inclined to think we shall have to adopt it. It is certainly equal to any in quality, and there is so much corn and so little cob that one really gets more for his money than with most other kinds of sweet corn.

Prof. Green, of the Ohio Experiment Station, speaks of it as follows:

IN GLEANINGS for Nov. 15, A. Jennie Wilson recommends Shoepeg sweet corn. This is the same as Ne Plus Ultra, or Banana. It is the most meaty and delicious corn that I ever tasted. The ears are not large, hence it might not be suitable for market; but it is unsurpassed for home use. I give the different names by which it is known, so that it may be recognized in the different catalogues. W. J. GREEN.

Columb is, O., Nov. 18, 1890.

In regard to the cantaloupe melons, we have tested Miller's Cream, and we thought that, if anything, it was a little ahead of the Emerald Gem; but rather than have so many kinds we thought we must drop it. As friend Lipscomb, however (on page 790), says it is a much *heavier cropper* than the Emerald Gem, I do not know but we had better substitute Miller's Cream. Can any of the friends corroborate friend Lipscomb's statement?

CONVENTION NOTICES.

The annual meeting of the Huron, Tuscola, and Sanilac Co. Bee-keepers' Association will be held at Bad Axe Court house, Huron Co., Mich., on Wed., Dec. 10, 1890. All are invited. KILMANAGH, Mich. J. G. KUNDIGER.

The fall meeting of the Carolina Bee-keepers' Association will be held in the Public Hall, Pineville, N. C., Dec. 18, 19. A good programme is prepared. All come, with full report. DERTIA, N. C. N. P. LYLES, Sec.

PUTTING BEES INTO THE CELLAR.

THE weather at this date, Nov. 26, seems to warrant us in putting our bees in the cellar. We are carrying them in this afternoon, and piling them up *a la* Boardman, without bottom-boards. Dr. Miller put his in two weeks ago, but he is in a colder locality than we.

THANKSGIVING TIME FOR TILLERS OF THE SOIL.

IN times past we have heard a good deal in regard to hard times for the poor farmer. In fact, there has been so much said about the farmers not having a fair chance (I presume the term "farmers" would also include market-gardeners), that it began to remind me of the old women's-rights question, and I didn't know but we should have to have a farmers'-rights organization. In fact, I presume we have two or three already; but I know so little of politics that I haven't even kept posted. Well, I want to say a word in regard to high prices on farmers' produce at this present time. I don't feel bad about it. In fact, I rather rejoice when I hear that any kind of farm produce is bringing a good price, and I rather enjoy paying it; but I mean, mind you, when everybody else has to pay it as well as myself. At present here in Medina we are paying 50 cts. a bushel for oats; 30 for corn in the ear; a dollar a bushel for nice potatoes; \$2.00 a bushel for choice apples, etc. Not only are prices good, but every thing seems to be taken up as fast as it comes into market. For several years I have felt sorry for the boys in our vicinity who raised popcorn. They brought nice lots of it to town, and I tried buying it for a while just to encourage them a little; but as we didn't get rid of it I had to give it up. Just now, however, there is great demand for popcorn, and none to be had. Our enterprising friend, H. R. Wright, of Albany, N. Y., sends out letters asking if anybody knows of any popcorn for sale anywhere. Friend W. buys and sells popcorn by the carload, and his printed letter-head makes quite a little circular in regard to the "popcorn business." Well, now, that is really encouraging. If there is any thing I do enjoy, it is seeing the boys get a good price, cash down, for something they have raised. When I find a boy who raises popcorn or chickens or honey or strawberries or onions, I just like to take that boy by the hand and claim relationship; and when our great nation of people get to where they can offer the boys encouragement in the way of good prices, we are on the road to better things. I allude especially to the boys that go out in the fields and work for themselves under God's clear sky, instead of hanging around the factories, begging for a chance to be "bossed" by somebody.

THE AMERICAN BEE JOURNAL.

ON the first of next year the old *American Bee Journal* is to change its size to about that of these pages, and each number will contain 32 pages. For a weekly bee-journal this is a big undertaking; but Newman & Son are equal to the task.

THE AMERICAN BEE-KEEPER.

THIS is the title of a new bee-journal, to be issued Jan. 1, 1891, and to be published by the W. T. Falconer Manufacturing Co., Jamestown, N. Y. It is to be a monthly periodical of 16 pages. The cover page and prospectus are before us, and we have no doubt that they will get out a first-class journal.

SPACERS FOR FRAMES.

EVERY now and then we receive a spacing-device for holding ordinary frames at fixed distances. They are complicated, and would make the hive cost anywhere from 10 to 50 cents extra, to say nothing of the length of time it would take to manipulate them. In suggesting these improvements it is well to bear in mind, first, their expense; second, their convenience. No Yankee can tolerate expensive devices, no matter how good they may be otherwise.

LIFE-MEMBERSHIP IN THE N. A. B. K. A.

IN order to become life-members in this association, spoken of elsewhere in these columns, all you have to do is to pay \$10.00 to the secretary; and when your name is voted upon and accepted, you will be a life-member, and no more *annual* dues to pay. Any one thoroughly interested in the success of the society (and that success means a great deal to our industry in general) can not do better than to become a life-member. If he be a straightforward man there will be no doubt that he will be accepted as a member.

FLAT COVERS.

IN going over our colonies in Dovetailed hives, preparatory to putting on the outside cases, we noticed that the clusters in some of the hives had settled down almost to the entrance, seemingly to avoid proximity to the cover. On other hives of the same kind they are quite close to the cover; and inspection showed that the former had been recently opened—that is, the propolis attachments making the cover airtight, had been broken so that the air would flow over their backs, and consequently they went down toward the entrance. Those colonies from which the covers had not been removed for some time, and which had been sealed down with propolis, were close to the cover. The same thing was seen in all our colonies in chaff hives with chaff cushions on top. Our apiarist, Mr. Spafford, thinks he would like to have the Dovetailed cover with side pieces, so that they would telescope over the body. There might be an advantage in this, but it makes the covers more difficult to handle during the honey

season; and when they are sealed down with propolis it is a pretty hard matter to pry them up, unless there are cleats on the hives, and we don't exactly want cleats yet. The moral is, to get the colonies fed up as early as possible in flat-cover hives, so that the bees may have time to seal the covers down air-tight. Simplicity covers are no better in this respect.

EXAGGERATION IN DESCRIBING GOODS IN CATALOGUES.

THIS matter is brought to my mind just now by a description of lemons in a weekly price list. There are three grades. They are designated, first, "Extra Fancy;" second, "Fancy;" and third, "Extra Choice." The "Extra Choice" is the poorest grade. I think I can remember the time when the poorest lemons used to be styled "Fair." Better ones were classed as "Choice." Pretty soon we had to say "Extra Choice" to get any real good ones. When the "Extra Choice" got to be only ordinary, somebody started the word "Fancy," and for a while we could be sure of getting the best in the market by ordering "Fancy." Now, however, we have to say "Extra Fancy" if we want the best; and if we happen to need the ordinary for some special purpose, they must be designated "Extra Choice."* What a sad, sad state of affairs! But somebody says, "What are you going to do about it? If you call your things exactly what they are, nobody will purchase. We are really obliged to do as others do." I heard a merchant in California say, when an exasperated customer gave him a blowing-up because his pound rolls of butter weighed only $\frac{3}{4}$, that the only way to live and get along was to give $\frac{3}{4}$, just as everybody else does. I suggested that he weigh them up by the pound, and tell every customer that they were $\frac{3}{4}$ -lb. rolls. He said nobody would buy them, because all the rest in the whole city of San Diego called $\frac{3}{4}$ of a pound a pound. Now, my friends, all this talk and this theory is false. It is not true. It *will* take you some little time to build up a business by telling the honest truth, *no doubt*; but when people get to know you, and to understand that you give full weight, and that, when you say "choice," you mean better than the average in the market, your fortune is made. There is no spread-eagle advertisement that can come *anywhere near* the *simple honest* truth, to build up business. Use moderate, simple, truthful, honest words. Make this your foundation, and all mankind will soon flock around you. If others act dishonestly, the field for you is all the wider and all the broader; and I have sometimes thought that, in some departments of trade, there is an almost *unexplored region* for the man who is actually and truly seeking "first the kingdom of God and his righteousness."

* When "Extra Fancy" loses its "saltiness," what words shall we take next?

FACTS! FACTS! FACTS!

The Bee-Keepers' Directory, 125 pages, price \$1.00. Thirty Years Among the Bees, 82 pages, price 50 cts. The Am. Apiculturist, one year, price 75 cts. The above paper and books contain all the information necessary to produce honey by tons, and to rear queens by thousands. All mailed for \$1.25. Sample copies of Apiculturist free. Address

Wants or Exchange Department.

WANTED.—To exchange forest trees, for strawberry-plants, grapevines, and all kinds of small fruit-trees or offers. **W. G. MCLENDON,**
Gaines' Landing, Chicot Co., Ark.

WANTED.—To exchange Italian bees in L. hives for beagle hounds, or will exchange fox-hounds for beagles. **J. B. MITCHELL,**
23-24d Hawkinsville, Pulaski Co., Ga.

WANTED.—To exchange apiary of 150 colonies of bees. Will take any kind of farm stock, goods or groceries. **ANTHONY OPP,** Helena, Ark.

WANTED.—To correspond with parties who wish to exchange beeswax for supplies. **GEO. RALL,** Frenchville, Trem. Co., Wis.

WANTED.—Apicultural offers in exchange for plain and fancy job printing. **23-24d C. W. DAYTON,** Clinton, Rock Co., Wis.

WANTED.—To exchange one 6x9 self-inking press, with type, for 10-inch fdn. mill and wax-extractor, or best offers; also a 6-inch fdn.-mill, for wax. **23-24d L. L. ISENHOWER,** Reading, Pa.

WANTED.—To correspond with parties having potatoes, onions, apples, and honey for sale. Prompt attention given to correspondence. Consignments solicited. Prompt returns made. **EARLE CLICKENGER,** 121 So. 4th St., Columbus, O.

WANTED.—Situation by a young man (20) living in Eastern Pa., who desires to learn apiculture with a first-class apiarist. All references furnished. Wages no consideration. Address **DANIEL S. HAHN,**
South Easton, Northampton Co., Pa.

WANTED.—A few pairs of ferrets and 500 lbs. No. 1 extracted honey. Will exchange pure Bronze turkeys. **CHAS. MCCLAVE,** New London, O.

WANTED.—To exchange a new foot-power saw for honey. Send for a descriptive circular. **W. S. WRIGHT,** Battle Creek, Mich.

WANTED.—To exchange fine Stainer violin, cost \$25, for a good 12-gauge, breech-loading, double-barreled shotgun. Also home-made saw-table, mandrel, and one Simmonds rip-saw—have cut out a large amount of lumber with it—will exchange for bees, honey, or offers. **D. H. TWEDDY,**
Dillonvale, Jeff. Co., O.

WANTED.—To exchange bee-supplies for printing, to the amount of about \$20.00. **24d WM. H. BRIGHT,** Mazeppa, Minn.

WANTED.—To exchange a single harness, or light double road harness, sleighs, one a light one, or two-seated buggy wagon, for a small planer, swing saw, and a power press for punching iron. **GEO. E. KNOX,** Ballston Spa, N. Y.

WANTED.—To exchange Perfect Hatcher, 176 eggs, cost \$75.00; and brooder, 300 chicks, cost \$38.00; been used at fairs a little, for Italian or hybrid bees. **ELIZABETH DIMICK,** Burns, Steuben Co., N. Y.

To the Bee-Keepers of Missouri.

I am requested by the secretary of the Missouri State Board of Agriculture to furnish him for publication a report of the bee-keeping interests of Missouri, and I ask every bee-keeper of Missouri to assist me in this matter by sending me a report of how many colonies of bees they had in the spring of 1890, and how many in the fall, how much comb and how much extracted honey they obtained, and how much wax. I would suggest you also give in the report of all your neighbors or persons that you know of keeping bees. Let me urge every bee-keeper to send in his report and assist in this matter. There are to be 4000 of the agricultural report printed and distributed, and we now have an excellent chance to help the bee-keeping interests before the people of the State. **J. W. ROUSE,**
Sec. Missouri State Bee-Keepers' Ass'n.
Mexico, Mo., Dec. 1, 1890.

NEW SPACERS for L. frames; accurate, 13, 92 to the pound. Fully practicable for frames in use. Prices, 1 to 5 lbs. at 10c, 5 to 10 lbs. at 15c, 10 to 25 lbs. at 14c. Send stamp for sample. Address **G. L. TINKER,** New Philadelphia, O. 24-124

Undoubtedly the Largest Plant in the West,

H. H. OVERMYER, Lindsey, Sandusky Co., O.

SPECIAL NOTICES.

ADVANCE ON WIRE NETTING.

Remember that only a few days remain before the advance price on wire netting takes effect. All orders received here by the 24th of December will be filled at the old price.

ENAMELED CLOTH ADVANCED.

After the catalogues, which we have sent out, were printed we received notice of an advance in the price of enamel cloth, and you will please note the following correction in price: 25 cts. per yard; \$2.75 per piece of 12 yards. Kindly mark this change in the catalogue you received before it slips your mind.

OUR HONEY QUOTATIONS.

Just after our December 1 number went to press, we received from the West the two cars of honey we had been expecting. One car of very nice white sage honey, in new cans and cases, is from J. F. McIntyre. This is fully equal to the former car from Mercer, and, being in new cans and cases, is more desirable on that account. In the car from Arizona, we have about 4000 lbs. alfalfa comb honey in 1-lb. sections, and about 1000 lbs. in 2-lb. sections,

as well as over 200 cases of two 60-lb. cans of alfalfa extracted honey. This is a good-flavored honey, and light amber color. There is a little second-grade amber color among the comb honey. This looks some worse than it really is, because the cappings are soaked. Some of the extracted is second grade. In order to work this honey off rapidly, and get it out of the way of our other business, we make the following low prices:

White sage, 1 to 3 cans, 60 lbs. each, 11c; 4 to 6 cans, 10.	
" " 5 to 6 cases, 2 cans " 9½; 6 to 10 cases, 9.	
" " 10 cases or more, 8½ cents per lb.	
Light amber Arizona, 1c per lb. less than white sage	
Amber " 1½ " " " "	
No. 2 amber " 2 " " " "	
Choice white comb, 1-lbs., 1 to 3 cases, 20c per lb.	
" " " 3 to 5 " " " 19 " "	
" " " 5 to 10 " " " 18 " "	
" " " 10 or more " " " 17½ " "	
" " " 20 " " " 17 " "	
Good " " " 1c less than choice.	
Fair " " " 2c " " "	
Dark " " " 3c " " "	

2-lb. sections, 2c per lb. less than 1-lb. of same grade.

Most of the comb is in 24-lb. cases, 48-lb. cases count two toward obtaining the quantity price.

2-lb. sections are 64 lbs. to case.

We shall be pleased to mail samples of extracted honey; and when you order, if you will return the sample or give the mark on it we will guarantee to send you honey equal to the sample. We can not send free samples of comb honey; and for the extracted, unless you have a purchase in view, send 5 cents to cover cost of sample. Those who get samples with the view of placing an order, of course will not be charged with them.

BOOKS FOR CHRISTMAS PRESENTS

We have purchased only one new book this year specially for the holidays. It is,

AN ILLUSTRATED PILGRIM'S PROGRESS. A nice book for a small sum. A few Sundays ago I took a notion to read the Pilgrim's Progress over again. I got it down and tried to see how many of the references to Bible texts I could repeat from the knowledge of the Bible I have gained since I read the Pilgrim's Progress when I was a child. I was very much pleased to find out, with a Bible right at hand, that I could repeat most of them—at least in substance. The book I was using had perhaps half a dozen illustrations in it. I finally said aloud to my wife, "Oh, I do wish that somebody would give us a Pilgrim's Progress full of pictures from beginning to end!" I want a nice large book that would be full of attraction to every child, and with pictures of such a nature that they would encourage wholesome truth and Bible precepts, even to those who can not read. Well, now, it is a little funny, that almost the very next day, the book I had been longing for was put into my hands. It is from the Charles Foster Publishing Co., Philadelphia, where the Story of the Bible comes from. The book is 9½ inches long, 7¼ wide, and 1¼ thick. It has 425 pages and 175 illustrations. Ever so many, to whom I have shown it, pronounce it a \$2.00 or a \$2.50 book; but by buying a very large number of them at a time we can sell them to you for only 75 cents. The book is so heavy, however, that it can not be sent by mail for less than 20 cents, making 95 cents by mail, postpaid. The covers are most beautifully embellished in scarlet and gold, and many of the pictures are worth to me alone the price of the book. Among them I would mention Christian and Pliable in the Slough of Despond; Mr. Worldly Wiseman; Giant Despair, etc. But the sweetest and best of them all to me, is Prudence talking to the boys. A single glance at the book by anybody, when you mention the insignificant price for so beautiful a volume, will make him hold up his hands in astonishment. We send a book as a premium for three subscriptions at \$1.00 each; or send us \$1.75 and we will send you GLEANINGS for 1891 and the book, postpaid. If you want something extra nice for a present, we can send you one with gilt edges for 25 cents more.

The following books we have left over from our premium list for last year. They are all, however, in nice order, with the exception of those mentioned otherwise, where a liberal reduction is made in consequence. They are as follows:

THE STORY OF THE BIBLE.

This wonderful book is the production of Rev. Charles Foster, of Philadelphia, lately deceased. It is the whole Bible reproduced in simple language, making a book of 700 pages, illustrated with 274 engravings. It is so plainly and pleasantly written that grown people as well as children, will hardly want to lay it down. In the hard passages in the Bible, difficult to understand, it

makes a commentary that will be thankfully received by some others besides children. Indeed, it has proven so simple, reliable, and helpful, that it has been reprinted in many foreign languages. It is a well made book, printed on fine paper. Regular agent's price is \$1.50. Our price is \$1.00; 15 cents extra if sent by mail, or given free for 2 new names and one renewal, with \$3.00, and 15c extra to pay postage.

STORY OF BIBLE ANIMALS. This is another book, same size and style as Story of the Bible—704 pages, 300 illustrations. It is a description of the habits and uses of every living creature mentioned in the Scriptures, with explanation of passages in the Old and New Testaments in which reference is made to them; by J. G. Wood, author of "Illustrated Natural History." If you are interested in natural history you will be delighted with this work. Children should read it to arouse their interest, and make them more familiar with the Book of books, by becoming more familiar with its animals. Regular agent's price, \$1.50. Our price is \$1.00. By mail, 15 cents extra, or given free for two new subscriptions and your own renewal, with \$3.00, and 15 cents to pay postage.

FABLES AND ALL GORIES; or, New Lights on Old Paths. This is a most magnificent book by Chas. Foster, the author of the Story of the Bible. It measures 8 by 9½ inches, by 1½ inches thick, and weighs 4 lbs. It is printed on very heavy toned paper, with heavy gilt edges; is bound in light-blue cloth, embossed in black and gold; contains 512 pages and 350 original illustrations. The subject-matter is a series of fables and allegories, each giving a most wholesome moral lesson that very few of us, old or young, do not need. This book would be an ornament on the center-table in any home; and if read and pondered, and its lessons put into practice, many hearts would become more lovely, and many homes more pleasant and beautiful. The lessons taught are made much more pungent by the pictures accompanying, as in many cases the story is more than half told in the pictures. So large and nice-looking a book is rarely sold by agents for less than \$4.00. Our price is \$1.50. By mail, 32 cents extra, or given for 6 subscriptions, with \$6.00, and 32 cents to pay postage, if sent by mail. Will sell two for \$2.80, three for \$4.00; five or more, at \$1.25 each.

BIBLE PICTURES. and What They Teach Us. This is a very handsome book by the same author, Chas. Foster. It contains 315 large illustrations from the Old and New Testaments, with brief descriptions. It contains 232 pages, 8x10, with embossed cloth cover, title in gilt, printed on heavy paper. The book weighs 2½ lbs., and takes 2 cents to mail it. It will make an excellent Christmas or birthday present for a child. It is written chiefly to instruct the children, and should be in every home. Regular agent's price, \$1.50. Our price, \$1.00. By mail, 20 cents extra, or given free for two new names and your own renewal for GLEANINGS, with \$3.00, and 20 cents to pay postage, if sent by mail. We have a few copies of these, also four copies of Story of the Bible, with covers somewhat damaged by water, which we will sell at half price.

FIRST STEPS FOR LITTLE FEET. This is by the same author, and is a collection of simple Bible stories intended more especially for younger learners. Every child should have one of these to read; 328 pages, and 140 illustrations. Very nicely printed, and bound in cloth, title in gilt. Price 50 cents each; 2 for 75 cents. Given free postpaid for 2 subscriptions, with \$2.00.

CONVENTION NOTICES.

The annual meeting of the Ontario Beekeepers' Association will be held in the city of St. Catharines Jan. 7 and 8, 1891. All interested are invited. W. COUSE, Sec., Streetsville, Ont.

HONEY COLUMN.

CITY MARKETS.

CHICAGO.—Honey.—There is not the volume of trade usual at this season; yet prices are without material change since last quoted. Best lots of white honey in one-pound sections bring 17¢@18; brown and dark grades are not so steady, and sell at 14¢@16; and where an entire lot of dark honey can be closed out these prices are shaded. The extracted product of this locality, and that of the Western States and Territories, brings 7¢@8. *Beeswax*, 27.
Dec. 8.

R. A. BURNETT,
161 So. Water St., Chicago, Ill.

ALBANY.—Honey.—The honey market is quiet; but stock is light and prices well sustained. We are selling, white, 16¢@20¢; mixed, 14¢@15¢. Buckwheat 13¢@14¢. Extracted, white, 8½¢@10; amber, 7¢@8; dark, 6¢@6½.
Dec. 6.

H. R. WRIGHT,
Albany, N. Y.

CINCINNATI.—Honey.—There is a good demand for all kinds of honey. Arrivals are fair of all but comb honey, and Southern extracted. Small lots only of each are arriving and disposed of on arrival. We quote: Choice comb honey nominal at 16¢@18. Extracted honey, 5½¢@8 on arrival. *Beeswax*.—There is a good demand at 24¢@26 on arrival, for good to choice yellow.
Dec. 8.

CHAS. F. MUTH & SON,
Cincinnati, Ohio.

KANSAS CITY.—Honey.—Fancy white one-pound comb, 18¢; fair to good, 17¢; dark, one-pound, 14¢@15; two-pound comb, white, 15¢@16; dark, 13¢@14. Extracted, white, 7¢; dark, 5¢@6.
Dec. 8.

HAMBLIN & BEARSS,
514 Walnut St., Kansas City, Mo.

ST. LOUIS.—Honey.—Demand continues good for comb and extracted. The former is scarce. We quote white-clover comb, 19; dark do., 15¢@16. Extracted, from 5½¢@6. *Beeswax*, prime, 25¢.
Dec. 8.

D. G. TUTT GRO. CO.,
St. Louis, Mo.

BOSTON.—Honey.—Fancy white one-pound combs selling at 19¢@20¢; fair to good, 17¢@18. No 2-lb. combs in this market. Buckwheat or off-colored honey not wanted at any price. Extracted selling at 7½¢@8½. No beeswax on hand. Demand good.
Dec. 10.

BLAKE & RIPLEY,
Boston, Mass.

DETROIT.—Honey.—Comb honey in one-pound sections in good demand at 15¢@17¢. Extracted, 9¢@9. *Beeswax*, in good demand, at 27¢@28¢. M. H. HUNT.
Dec. 11.

Bell Branch, Mich.

ALBANY.—Honey.—The demand has been more brisk the past ten days; especially for extracted; and we have closed out about all we had on hand. We think the stock of comb honey is now nearly all on the market, and do not anticipate any decline in prices. We quote: White comb honey, 17¢@18; mixed, 15¢@16; buckwheat, 12¢@14. Extracted, light, 9¢@10; dark, 7¢@8.
Dec. 9.

CHAS. McCULLOCH & CO.,
339 Broadway, Albany, N. Y.

NEW YORK.—Honey.—Fancy white, 1-lb. sections, 16¢@18; fair to good, 1-lb. sections, 14¢@15; fancy white, 2-lb. sections, 15¢@16; fair to good, 2-lb. sections, 13¢@14; fancy buckwheat, 1-lb. sections, 12¢@13; fancy buckwheat, 2-lb. sections, 12¢@13; extracted clover and basswood, 9¢@10; extracted buckwheat, 7¢@8. The above are about the prices these goods are bringing to-day. Of course, after the holidays, we expect a lull in the honey market as usual, and expect no great demand for it for two or three weeks after New Years. The market is pretty well cleaned up in 1 and 2-lb. sections of fancy clover and 2-lb. sections of buckwheat, as you will see by the prices these goods are bringing. On the whole we think the honey producers have got good prices this season.
Dec. 11.

CHAS. ISRAEL & BRO.,
110 Hudson St., N. Y.

FOR SALE.—Comb and extracted honey. Address
O. H. HYATT, Shenandoah, Ia.

FOR SALE.—Choice honey in sections, cans, and C. pails. Send for price list to
12-tfdb. OLIVER FOSTER,
Mt. Vernon, Ia.

WANTED.—Southern honey. Will pay 5½¢ cash on arrival for good Southern honey.

CHAS. F. MUTH & SON,

QUEENS STINGING WORKERS.

TWO QUEENS IN A HIVE: THE YOUNG ONE SUP- PERSEDED FIRST.

Several years ago I saw a young queen, that had just hatched, grasp hold of a worker in a kind of awkward embrace; and the worker, which had previously appeared all right, was dead when the queen let go. Heretofore I never dared to report this case, being so firm in the belief that a queen never stings any bee except a queen, and never seeing any exception reported, that I thought there might have been some mistake in my observation.

A second case of the same kind having occurred this summer, which my assistant also witnessed, I feel safe in saying that, in rare instances, a young queen may sting a worker.

During the past summer I experimented somewhat largely with queen-cells and virgin queens. I wanted to decrease the chances for swarming by means of young queens, for I believe it is pretty generally conceded that a colony, with a young queen of the current year, is less likely to swarm than one with an older queen. I read in Doolittle's excellent book, that it is dangerous to allow a young queen to hatch in a hive where there was an old queen, as the old queen would be destroyed if the colony did not swarm. I said to myself, "Now I have it. I'll get a young queen into the hive before there is danger of swarming. She'll supersede the old queen, and very likely there will be no swarming that season. Certainly there will be none for a good many days after the young queen takes possession, and, if necessary, I can again supersede her before she is old enough to swarm. I believe I've struck it at last." Then I made a lot of Doolittle's cell-protectors, put a sealed queen-cell in each, and put in each hive to be operated on a cell thus protected. The cell was put between two combs, just under the top-bars, a place being made for it in the combs by pressing with the

ends of my fingers. As soon as it was time for the cells to hatch, or perhaps sooner, I went with no little interest to find what progress was made. I found every cell destroyed by the bees. I had put the cells in horizontally; the protectors were pretty large for the cells, and when the bees pushed against the point of the cell it fell back into the protector, thus letting the bees inside gnaw into the side of the cell. I said, "All right. I've lost my cells, but I've learned something." So I tried another lot, and put them in perpendicularly, point down. Again I examined with eagerness, and found some of the cells intact and some open. Were they torn open by the bees, or had a queen hatched out? I couldn't tell. Finally I came to one which made me call out to my assistant, who was equally interested, "Come quick, Em. See that?" To which she replied, "Sure as any thing. There's the hinged cap. A queen has hatched out of that cell, wherever she is now."

We looked but a short time, and found the young queen. A little to our disappointment, we also found the old queen. "Let's take her away," said Emma, "and then this colony's all right."

"No," said I, "I want to follow this out to the end. Let them both stay. We're sure the two queens are here now, and we'll see whether the old queen will be destroyed and replaced by the young one."

Subsequent examinations revealed the fact that, in some way, the young queen had disappeared. Others turned out the same way. The cells showed that a queen had hatched out, but later examinations failed to denote her continued presence. Out of 55, all failed with but a single exception. In that case the protected cell was given May 28, and 16 days later the young queen was clipped. A number of very young queens were also placed directly on the combs, and met the same fate. Whether I did something different from Doolittle, or whether the poor season had something to do with it, I don't know.

I think that, if the old queen were removed, the protected cell would be respected; but, for that matter, so would a cell without the protector.

"PULLED" QUEENS.

It is pretty generally known, that a very young queen may be put into a hive, and usually allowed to remain unchallenged, if no old queen is there. It may not be so generally known that queens may differ no little in age at time of hatching. A single cell in a queenless hive will hatch out a white soft-looking thing, not able to fly for some time. In a hive having sent forth a prime swarm, at the time of sending forth the second swarm there will usually be found a number of young queens in cells, some of them immature, some of them like the white soft things already mentioned, and some of them ready to fly. The same state of affairs will be found in a strong colony from which the queen has been removed, although it is questioned whether the queens are as good. When one of my colonies with a clipped queen swarms and returns, and the queen is lost or removed, then I find a goodly number of cells, the quality of which will be questioned by no one. For a few years I have made a practice of saving such queens, at least all that I could find use for, if the stock suited me. Please bear in mind, that the white-looking ones are old enough to use, and I suspect that they are much easier to introduce than those that have been imprisoned by the bees in their cells till they are strong enough to fly. I do not wait for any of these young queens to hatch out. I take out a frame with cells, take hold of the end of a cell with the nails of my thumb and finger, and pull off the cell. If the queen is one of the oldest, the cap of the cell will pull off, and, after a little hesitation, the queen will emerge. If the queen is younger, the whole cell will pull off, and a little pulling apart at the larger end of the cell will set the queen free. All the cells are thus taken out of the hive, any queens too young, or with immature wings, thrown away, and the rest put in cages. These are then given to any colony or nucleus needing them, dropping them directly among the bees, with no preparation or caution whatever. These "pulled" queens, as we call them, are, I think, just as good as if each one had hatched out of its own accord; and when such cells are plentiful, a large number can be had in a very short time. Mr. A. I. Root was here one day when we pulled a lot, and seemed quite interested. C. C. MILLER.

Marengo, Ill., Nov. 13.

I, too, friend M., have seen queens, once in a great while, sting a worker-bee; but it usually happened under the influence of excitement or alarm, so that she could hardly have been said to be in a normal state. I have introduced young queens into a hive containing an old queen; but my experience has been about like yours. Yes, I remember about the "pulled" queens; but there were so many things to see when I made you that visit that it is not any wonder that I failed to mention some of them.

WINTER REPOSITORIES, ETC.

DOOLITTLE SUGGESTS SOME THINGS TO AVOID.

On pages 816 and 817 I find a description of a winter repository as given by Harry Lathrop. There is not the least doubt that it will winter bees splendidly; and if Bro. L. can stand the racket of renewing it as often as may be needed,

and take the risk of a "cave in" on the bees while in the repository some winter, should he not renew it when it should be, he is all right as he is. My first repository, or "mud hut," as such repositories were then called, was built on almost exactly the same plan as his; but it lasted only three years so as to be safe.

The trouble seems to be, that, during winter, the wood part of it becomes saturated with the moisture arising from the bees; and as, in the summer months, it does not seem to dry out as it should, just the right condition comes about to cause the wood to decay quickly. Wood that would otherwise last for years will decay in three years so that there is no safety in it, according to my experience, as I have three times had to throw all the dirt out of my bee-cellar by its caving in when I did not expect it. After the first one rotted out I built the side-walls of mason work, on which was made a regular roof of rafters and boards, the same as a roof is made for any building, less the shingles. The dry dirt was now placed on this roof to the depth of three feet, and a cover put over the whole, so that the dirt never got wet at all; yet at the end of three years I could stick the blade of my pocket-knife through any of the boards. I now put in extra sets of rafters so that none of these rafters were more than eight inches apart. This held the earth all right till the rafters gave out, as an eight-inch space was too small for the earth to fall through after it was packed as it was by this time, especially as the old rotted boards helped a little to keep it in place. When the rafters gave out I renewed the roof again; but this latter one did not last as well as the first, so I decided to cover the top with flagging.

As I gave a full description of the cellar a year or two ago in GLEANINGS, together with illustrations, I will not describe it further at this time, more than to say that the repository proper is 24 feet long, 7 feet wide, and 6 feet deep, inside measure. As I could get no flagstone thick enough to hold the weight of dirt if they were laid directly across the wall, I procured them a little over four feet long and set them up the same as rafters would be set up, resting the foot of each on the side-walls, while the tops rested against each other, the same as rafters would. This gave me the height of 8 feet in the center of the cellar, and I am very glad now that I could not get the whole stone thick enough; for had I been able to do so I should have had my hives sopping wet all the while.

No one, who has not had experience, would believe the quantity of moisture which will arise from a lot of bees in a cellar. The bees have been in the cellar but about 20 days; yet these same flagstones, which at that time were as dry as could be, have drops of water coursing down their under surface to the top of the wall, so that it stands in little puddles there. What effect this will have on the bees before spring, I am unable to say; but I fear no trouble as long as this moisture can be kept from the hives, and the temperature kept at from 43° to 45°, the same as it has formerly been.

In using flagging for covering I find that the stone must be at least three inches thick. The stone to cover this cellar cost me \$25.00, delivered. Besides those which were intended for the cover I had some thinner ones to use as battens for the cracks between the stones, as all of the covering stone were not dressed at the sides. After the stone were delivered I found it was necessary to use one of them over the threefold doorway, so I used one of the stone intended for a batten in the main roof, and on top of this I put another one of the battens, thinking that the two, which were somewhat

thick r than one of the others, would hold all right. After I had the whole thing completed I found that the upper one of these stones had broken in the middle, but still I thought the under one would hold. This was not to be, however, for at the end of two weeks the other broke; and as four of the other stone were more or less connected with it, they came down also. This caused a third of the whole to cave in, which made a lot of trouble and much extra work, besides some fears that the whole stone might not hold. In a week's time I had it back again as good as ever; and as it has been over two months now since it was completed the last time, I think there will be no further trouble from its caving in. If not, this cellar will be here years after I am dead and gone, and for all time, so far as I can see, unless some one tears it down.

WAX-EXTRACTORS.

Now, friend Ernest Root, if I understand your description of how you make the Doolittle solar wax-extractor aright, and I think I do, when putting the description and the engraving together you have spoiled one of the *most valuable* features of it. If I am right, your glass-frame drops down $\frac{3}{4}$ inch into the rabbets made in the sides of the extractor to receive it. This necessitates the lifting of the frame up bodily in order to remove it, or to do any of the manipulating of wax or scraps in putting in or removing, while all that I do with mine is to lift one end of the sash a little by taking hold of No. 11 and slide it a little to the front or back; slide it back and on again; No. 4 and the extractor making a track for it to slide upon. The glass sash or frame is not removed from my extractor in one manipulation out of twenty. Well, why not remove it? Because it is more work, for one thing; but the main reason is, that in all times of scarcity the bees will collect in swarms about this extractor in less than a minute after the cover is raised so as to let out the perfume of the wax; and every bee which is shut in the extractor is dead in a twinkling. With my sash I can slide it under the hovering bees, and manipulate it quicker also, which will be impossible to do with a sash that must be lifted with every manipulation. After I learned to slide the sash I did not murder one bee where I did hundreds before.

G. M. DOOLITTLE.

Borodino, N. Y., Dec. 1.

I suppose, friend D., you still adhere to the plan of having no ventilators in your bee-cellar. When you spoke of the water condensing on the inside of the stones, it occurred to me that the right amount of ventilation would remove all this water. But then we come right on to a difficulty in all such structures. It is this: Whenever we have a warm spell so that the outside air is *warmer* than the air, stones, etc., in your cellar, if your ventilators are open, moisture will be deposited over every thing. A few days ago our new machine-shop was filled with machinery ready to start, before any heat had been put into the building. The weather suddenly changed from freezing to a warm, damp south wind. The tools and walls of the new shop were a good deal colder than this damp air. The consequence was, every time we opened a door or window, great drops of water appeared on all the metal work; and before we could stop it our whole lot of nice machinery was covered with rust. A lot of boys went to work with waste and oil, but it did us

a great deal of damage. Gregory, in his squash-book, speaks of the same thing in his house for keeping squashes, and he directs to shut up the building air-tight (or as near as you can) whenever there is a damp air outside, of a *higher* temperature than the air inside. This necessitates careful watching and prompt opening and closing of ventilators. It seems to me, however, that this is next to impossible with a bee-cellar; therefore I would do as you do—shut the whole thing up as tight as I could and let it alone. And I am not sure but I would do the same thing with potatoes and other vegetables in a cellar. When the cellar is *too warm*, however, I would advise opening the doors and windows long enough for it to cool off to the desired point. But I would do this only during very dry or freezing weather. As soon as it begins to freeze in the open air, the surplus moisture is practically done away with. Now, I suspect one of the troubles with sub-earth ventilation is in this line. Air that comes up through an underground passage will, as a matter of course, be filled with moisture; and it would be just the condition to make every thing rot and decay that it comes in contact with, just as it made your boards and rafters rot and decay. In cold-storage buildings they have an arrangement to take all the moisture out of the air so as to have no dampness on the walls and fruits and vegetables; but it is a somewhat complicated and expensive arrangement. Putting a stove into the bee-cellar, and drying it off, will, of course, fix it; and had we set up some stoves in our machine-shop, and warmed up the walls and the metal work promptly, it would have saved the rusting, and probably paid for the expense of putting up the stoves or something equivalent. I have taken some space to go over this, because it is an important matter; and much damage is often done in the way I have indicated. It is just like the “sweat” on the outside of a pitcher that contains cold water from the well, or ice water. Every little while somebody lifts up his hands in astonishment because the contents of a cellar or certain room are dripping wet; and most people regard it as one of the strange mysteries. The whole thing, however, is very simple, and easy to manage, if we recollect that dew is always deposited copiously when warm damp air strikes any cold body.

In regard to the wax-extractor, Ernest replies as follows:

Yes, friend D., the sides of the new wax-extractor are rabbeted out $\frac{3}{4}$ inch deep. The rim for holding the glass is $1\frac{1}{2}$ inches deep, leaving a projection of $\frac{1}{4}$ inch to get hold of, above the sides or ends of the box. Perhaps I do not quite understand, but I think the cover can be slid back in the same way that you speak of, so as to leave an opening as large or as small as may be desired for putting in bits of wax. We tried to make it just as near like yours as pos-

sible, and yet simplify its manner of construction with reference to machinery.

KODAK VIEWS OFF THE BICYCLE.

AT MR. ELWOOD'S.

In the last issue I said that I had concluded my Notes of Travel. Well, I have not altogether yet. You will remember I took along

ONE OF MR. ELWOOD'S OUT-APIARIES.

my Kodak, and at various places in my notes I promised that I would, *later*, give reproductions of some of the scenes and of some of the things it was my pleasure to see. I took one hundred pictures, and carried the whole apparatus in a small leathern case, 7x3½x4, under my bicycle seat. In fact, the little camera and the case were so small that it might easily be taken for a tool-box, and I was quite willing that that impression should prevail, because I did not wish my valuable collection to be stolen or tampered with. The whole hundred pictures are now mounted, and are good ones, and I assure you it is a pleasure to haul them over and show them to my friends. They form the best kind of a permanent record of my visit at various places. For instance, when I stopped at a place I was not obliged to pull out my note-book and take extensive memoranda of hives and appurtenances. No, I just took out the little Kodak and let it "wink," as it were, at the object of which I wished to retain a permanent impression, and it did its work well, although I am sorry to say that I can not reproduce in half-tone the pictures as nice as they appear in the photographs.

You will remember I took a number of views while at Mr. Elwood's. One in particular was of a hive as he uses it. If you will look back you will see that it was taken under somewhat adverse circumstances. The bees were stinging, and were making things rather lively for Mr. Elwood and myself. The photograph shows that the air was full of the mad little rascals, although the half-tone reproduction does not present them very distinctly. For the present I pass this by, as it will appear along with some forthcoming papers from Mr. Elwood's pen.

I have referred, a number of times, to the hills about Mr. Elwood's apiaries. I present you one view above.

The hills in the rear do not appear to be very

high; but the fact is, they rise one above another. The first range rather hides those behind it in the picture.

Proximity to hills or mountains is doubtless a grand thing for the bees. In a good many cases they form a magnificent protection against the prevailing winds, and then they prolong perceptibly the honey-season. As the basswood opens up, the bees will gather from the valleys. Then as the season advances, instead of its stopping as it does with us in about ten days, the flight of the bees gradually goes upward, upward, upward, upward, until they reach the summit of the topmost hill, when the basswood season ends. Although I have heard this stated many times before, this was an exceedingly interesting point to me, as I looked at the hills covered with basswoods.

Around this particular yard there was a single strand of barbed wire. Said I, "What is this for?"

"To keep calves out," said Mr. Elwood, jokingly.

On a former occasion some of these young ruminants had been meandering around among the hives, and had tipped a few over. Very likely they were suddenly put to flight by some of the hybrids, and took the shortest cut out of the yard; and if a hive happened to be in their way, it did not matter much to them, even if they tipped some of them over. As all his bees were in closed-end frames, no serious result followed; for no calf can make the frames, if they are the closed-end, shuck about.

AT WESLEY DIBBLE'S.

I told you, on page 748, Oct. 15, about Mr. Dibble's automatic swarming-arrangement, and mentioned the fact of my having taken some Kodak views. Well, here is one.

WESLEY DIBBLE'S AUTOMATIC SWARMING-DEVICE READY FOR THE SWARM.

Mr. Dibble uses hives very similar to our Dovetailed. When a hive is about to send forth a swarm he places a twin hive beside it, about seven or eight inches off. Connecting the two very near the entrance is a tube about 1½ or 1¾ inches in diameter, made of perforated zinc. This tube, of course, is let into holes in the outside of each hive, near the front of the hive, so as to form communication with the two. The entrances are closed with a strip of perforated zinc. When a swarm issues it comes out and fills the air in the regulation way. The queen comes to the perforated zinc at the entrance; and on finding egress denied her perambulates back and forth until she discovers the before-

mentioned hole in the side of the hive. She passes through this; and on vainly trying to get through the perforated tube she enters the other hive. By this time the bees are beginning to return, and, not finding her in the parent hive, a few of the stragglers discover her presence in the next hive, and call their companions to them. The engraving shows the perforated zinc tube connecting the two hives, and I think it will make the matter sufficiently plain.

Mr. Dibble told me that he successfully hived swarms automatically last year and this in out-apiaries, and the invention enabled him to dispense with hired help. So far as he was concerned, he was original in its use, having worked along in a quiet way by himself.

The next engraving shows nicely a Kodak view of his little smoker-house, or shed. It is not large enough for a man to enter, as you see. His son, a young man, stands by its side, so that you can get its relative height. In the lower part is put his smoker wood, if I remember correctly. In the upper part are smokers and other tools for work among the bees. A hinged door closes the thing tight from the weather. It is situated within convenient access from any part of the apiary.

We have had tool-boxes in the shape of Simplicity hives stacked up in our apiary for years. The objection to them was, that honey-knives, wood, and smokers, would be all mixed together in the bottom. With the arrangement above there is a convenient shelf, so that the tools can be separated from the fuel. Mr. Dibble regarded it as a valuable adjunct to an apiary, and I have no doubt that many of our friends can profit by the suggestion by setting one up and trying it.

I told you some time ago how Mr. Doolittle and I together went through his yard examining into his queen-rearing colonies. And you will remember that he showed me quite a number of frames having his artificial cells nicely completed and ready to be removed and put into hives. You will remember, too, that we examined them at random, and I know that Mr.

These half-tone engravings are a faithful reproduction of a photograph, just as nature actually was at the time of taking the picture. You will observe there are 7 complete cells hanging to the top-bar, as it were, in the center of one of Mr. Doolittle's frames. Two others the bees had failed to build out; but by putting in more larvæ they would ultimately finish them up.

DOOLITTLE'S ARTIFICIAL QUEEN-CELLS
ILLUSTRATED.

No one can deny that Mr. Doolittle's method of queen-rearing is a success in his hands; and if in his, why not in all? The reproduction does not show the cells as distinctly as the photograph, but there they are, just as Nature completed them from the artificial bases.

ERNEST.

INVENTIVE PROGRESS, ESPECIALLY IN THE LINE OF ELECTRICITY.

SOME BRIGHT THOUGHTS AS WELL AS PRACTICAL SUGGESTIONS FROM FRIEND HEDDON.

Friend Root:—I was not a little interested in your recent editorial regarding the rapid strides in electrical invention. As I have been for some time, and am at present, making electricity a study, I thought of a few words I should like to say to you and your readers regarding just such schemes as friends Dadant speak to you about, regarding utilizing the immense water-power of the Mississippi River, Niagara Falls, and other places. I want to say to you, that the cost of electrical apparatus, and wire for conveying the current long distances, is such that water-power of ever so great capacity is of no value whatever, unless it be located very close to the spot where the power is utilized. Very large insulated copper wires are enormously expensive; and unless such are used, even with the highest-tension systems, the loss, or "drop," as it is called, in electrical parlance, becomes so great that the utilizing of water-power at long range is impractical. Many of the best electricians of the country with whom I have come in contact, tell me that all of the electrical inventions of the present time are merely mechanical improvements here and there, and that no great innovation may be looked for, in any direction which they can

DIBBLE'S SMOKER AND TOOL HOUSE.

Doolittle did not pick out his best lot of cells when my Kodak took a shot. The view next presented, I think, is the first one I took. When they were photographed he was hardly aware of what I had done; and yet here it is, preserved as a permanent record of the everyday queen-rearing in Mr. Doolittle's yard.

conceive, except it be the converting of heat from the combustion of fuel directly into electricity without having to go around through steam with engines and dynamos. If this can be done, and they say the signs of the times are favorable, then we shall have the splendid arc and incandescent lights at a price even lower than the cost of gas or kerosene.

Four of us procured a franchise, and installed in this city an incandescent plant, about a year ago; and after nearly a year's experience we have not yet discovered any mistake in our choice of system and apparatus. Of course, we visited numerous plants before selecting. Of the seven bids from seven different companies, we accepted the highest-priced of all, a price nearly double the lowest, and feel that we did just right, as the dearest proved to be the cheapest in the end. We light our streets with 32-candle-power incandescent lights; and for the resident part of any village or small city like our own, ornamented with well-developed shade-trees, the incandescent light beats the arc light more than two to one. Of course, the arc light is larger and brighter, but the incandescent is so much cheaper that we can afford nearly ten times as many of them at the same cost. We can place them low enough so that there is no sidewalk in the city on which you could not see your jack-knife lying, or tell what time it was by your watch, in any spot or place on our streets, the "darkest night that ever blew."

Our citizens laughed at us when we put in the incandescent lights, but now they are all more than satisfied, and can see the wisdom of the choice of our city council. All of our best business houses are lighted with the incandescent lights, compared with which the best kerosene lamp looks like a phosphorescent beetle, or "a convalescent white bean," as Bill Nye would say. We use the high-tension alternating-current system, with the Westinghouse apparatus (the best in the world); and just here it may surprise many of your readers when I tell you that there is no doubt in my mind but that George Westinghouse is a much greater inventor than Thomas A. Edison, not only in all the realm of mechanical inventions, but even those connected with electricity. But this article is long enough. JAMES HEDDON.

Dowagiac, Mich., Dec. 2.

Friend H., we are very greatly obliged to you for the information you give us. From what we know of you, we are not at all surprised to know that you, too, have been attracted by this matter of converting mechanical power into light. Very likely you are correct in regard to transmitting the electric current long distances. We are beginning to see something of it in carrying our wires for electric lighting to different parts of our plant. I, too, have been watching for some great developments in the way of a shorter cut from heat to an electric current.

SHIPPING AND INTRODUCING CAGES.

HOW TO MAKE AN EXCELLENT INTRODUCING-CAGE.

Friend Root:—I have just been sizing up your new Benton shipping-cage, and it meets my hearty approval in every way. With good fresh candy, or, rather, with fresh Good candy, and 20 or 30 bees, it should deliver 95 per cent of all the queens sent to California, in good condition.

The introducing feature does not hurt it a particle for shipping, and the party receiving it can use that part or not, as he thinks best. I usually prefer to use some other plan with queens coming from the East, for several reasons. As a rule, the longer a queen has been caged without access to comb, the longer it will be before she commences to lay after being liberated. A queen coming from the East, usually takes from two to three days to get in condition and commence to lay. Before this time she is almost as hard to introduce to a full colony as a virgin, therefore I always introduce her to a few young bees until she commences to lay, and then introduce her to the full colony.

Another reason why I do not use the shipping-cage for introducing is because the bees often have so much of the candy eaten out that the queen would be liberated in a few hours; in which case if the reigning queen had just been removed, the new queen would surely be killed. Those objections do not apply to queens shipped a short distance, because the queen would be ready to lay almost as soon as liberated, and the bees would have very little of the candy eaten out. I believe a colony of bees are in the best condition to have a strange queen liberated among them when they have been queenless long enough to have a capped queen-cell from three to five days; they seem to think the queen has come out of one of the capped cells, and it is all right. Of course, the queen should be caged in the hive one or two days before the bees liberate her, to get the scent of the hive. She should be caged on the comb while the bees are eating their way in, so when they break into the cage they will find her in a normal condition, depositing eggs. The cage I use for this purpose is a simple affair. I take a piece of wire cloth $5\frac{1}{2}$ inches square, cut little pieces $\frac{3}{4}$ of an inch square out of each corner, and bend the four sides at right angles, making a box 4 inches square and $\frac{3}{4}$ inch deep. Into one corner of this box I fasten a tube of wood or tin $\frac{1}{2}$ inch in diameter, and two inches long, which is filled with Good candy, for the bees to eat out and liberate the queen.

M'INTYRE'S INTRODUCING-CAGE.

I use this cage altogether in my apiary, for changing laying queens from one hive to another. I kill my old queens when they are two years old, and introduce young laying queens in their place. My practice is to go to the nucleus with the young laying queen; lift out the comb with the queen on, and press one of these cages into the comb over the queen, and what bees may be around her. Carry this comb to the hive with the old queen; find and kill the old queen, and place the comb with the young queen caged on it in the center of the hive, taking one comb from the hive back to the nucleus. In a week I go and take the cage out and find the young queen laying. When I receive a valuable queen from a distance I liberate her at once on a comb of hatching brood, with

some young bees; and when she commences to lay I introduce her as above. J. F. McINTYRE.
Fillmore, Cal., Oct. 21.

The success of the Benton cage for sending queens across the continent to California has been phenomenal; but within the last few days it has failed to deliver the queen alive. The cages, at our request, were returned, and on inspection we found that the candy had become as hard as a rock; and the poor bees and queen, not being able to use it as food, simply starved to death. The fault, then, after all, was not in the cage, but in the *candy*. We next tried the Manum bee-candy, and that for some other reason did not answer. The cold weather coming on, I rather suspect has had something to do with it; for, during the warmer months of the year, the Good candy has worked. We now rather look to the Morrison candy. The latter, Mr. S. W. Morrison says, works perfectly during all weathers, and is always soft.

We have had large experience in introducing—yes, introducing hundreds every year in our apiaries, and we don't want a colony queenless more than one or two days, at most, for safe introducing. We have the best success with a colony that has hardly had a *chance* to make preparations for a new mother. The point is this: That when those preparations are once begun (cell-starting) they sometimes seem *determined* to carry out their original intentions; and so we prefer to *get the start* of the bees by giving them a new queen before they have time to realize their queenless condition. If *we* wait until cells are capped, the bees are more apt to kill the queen when released. Some good authority, I don't recollect who, now, corroborates this. Still further, when we take out one queen we frequently cage another at the same time. In fact, we generally do so, and never have a failure except when there is a dearth of honey, and the whole apiary is disposed to rob.

Now about your cage. The principle is certainly good. It combines the good principles of the old Peet with the later and more convenient candy method. For introducing alone, I believe it is the best.

It is a big thing to give a queen access to comb just as soon as she reaches her destination, especially for you Californians. E. R.

BEES ON THE ISLAND OF MALTA.

AN INTERESTING LETTER FROM THE ISLAND,
FROM ONE OF OUR OLD CORRESPONDENTS
IN QUARANTINE.

Dear Mr. Editor:—After a trip of five days by sea we arrived, coming from Jaffa, at the island of Malta. I changed steamers at Port Said at the Mediterranean entrance of the Suez Canal. When we were in sight of Malta, the captain said: "A queer place, this Malta. They have strange notions as to quarantine." And, indeed, it turned out very queer, having no common sense about it. The three cities lie around

a number of creeks where a number of men-of-war are stationed. It affords place for many other vessels. Steamships are continually running into the harbor, which is a great coaling station. Our steamship ran into French Creek, conducted by a Maltese pilot. The sanitary officers came on board, and, after examining my papers, marched me (or, rather, rowed me) off into the quarantine, together with the pilot, as having touched the steamer on which I came, the cholera being 300 or 400 miles north of Jaffa. The steamship itself, the passengers, and crew, had a fair bill, and were allowed to land, together with the sanitary officers. I had to sit alone in a room for the next eight days. I was properly fumigated, and robbed of as much money as possible, with the least possible comfort—enough to make a person, traveling for the restoration of his health, to become eventually sick, under the protection of the Great Britons.

THE HONEY, AND HOW THE ISLAND OBTAINED ITS OLD NAME.

Being in the hospital, or lazaretto, a bee, black as jet, fell down before me. I saw that the bees of the island are, if not identical, at least very much like the Tunisians. Melita of the ancients was, very likely, named so by Greek settlers, who changed the name of Ogygia into Melita, now corrupted by the moderns into Malta. *Melita*, very likely, means "the honey-producing," although the constant advance of agriculture has brought apiculture to a low scale. The island is about 60 miles in circumference—12 wide by 20 long. The climate is very favorable in every respect.

At the western end of the island, about Calypso's Grotto, the best honey is produced from the wild thyme, growing more abundantly there than on the rest of the island, whither the bee-keepers all take their hives in summer. Owing to the rocky and treeless East, this part may have been still more beautiful in ages past, for Homer calls it

A scene where, if a god should cast his sight,
A god might gaze, and wonder with delight.

But it does not even make a human being wonder with delight now. The poet made Calypso live there. There is a spring, and it might have been nicely fitted out at one time, but none of those groves are to be found there excepting carob-trees, which stand about almost on the bare rock, and supply a very dark-colored honey in spring. Wandering down the hill

Where bloomy meads with vivid green were crowned,
And glowing violets threw odors round,

as the same poet says, may, as much as the before-mentioned, have met the eye of the traveler after a weary voyage on a slow-sailing vessel, and coming, perhaps, from the barren shores of Tripoli, landing in the Bay of Melleha, which again derives its name from honey, his fancy made it fit for gods to dwell in. Near by is a dry river-bed, all in rock, covered here and there with carob-trees, called by the natives "Oued-el-asel," a pure Arabic name, denoting the quantity of honey there produced. It is translated "Valley of Honey." A priest told me that, more than 70 years ago, many bees lived there wild, and probably the masses of honey they got there made them give such names. The natives bring the hives here and have them shut up in caves, before which walls are built, with small holes for each colony to go in and out. An iron gate closes the very low entrance. They greatly fear being robbed by such as have a good taste for sweets, and, more, "covet their neighbors' property." The owner of the place gets 5 to 8 pence a hive for his hire during four months.

THE POOR SEASONS IN MALTA.

There are no statistics to give as to how many hives there may be on the whole island. A canon told me there might be about 1000, which in good years may yield an average of 10 lbs. a hive. The season of 1890 seems to have been a failure. The canon, who possesses some 60 hives, which are in his garden on a cape, has had 4 lbs. of honey from the whole lot. He has spent a good deal of money in transferring his hives into Italian-made hives, and has lost a good many swarms, from moths, dwindling, fertile workers, etc., and is now fast transferring them into the Sandringham hives. He reads Italian bee-papers, and takes every thing for granted that these papers say, and follows the same innovations. He has any amount of queen-excluding zinc, sections, feeders, and so forth; has also brought numbers of queens from Italy, a few Cyprians, but he does not believe in one race stinging more or less than another. Another gentleman very satirically remarked to me, "This part of the island, where not less than 200 hives of bees are kept within a radius of a few miles, and no flowers worth talking about, is just good enough for spending one's money in feeding and breeding bees for the pleasure of seeing them flying and working." He, too, had about a dozen colonies in Sandringham hives, and is feeding the bees to give them a fair living. A third gentleman, too, an amateur, who only looks at the busy creatures, took some honey a year ago, but ultimately had to feed back "over and above" what he had previously taken, so now he has concluded to let 'em alone; and, besides, it was very cruel to take away the honey they had so carefully gathered. The above named are foreigners.

THE MALTESE BEE-KEEPER.

The Maltese bee-keeper is quite a different chap. As superstitious as his oriental relations, he is as far back in bee-keeping as any one else. The hive is made of earthenware, cylindrical, and costs about 8 pence. Its length is nearly 15 inches, and diameter about 10. When this is full he puts another cylinder, about 12 inches long, at the back. As a rule he takes only the honey which is stored in this prolongation, after having blown some smoke on the bees (the smoker is only bovine which he blows into the hive, as they have no smoking-implement). The more timid bee-keeper wears a veil and gloves, while the expert does not. They transport the bees on a car, with plenty of straw to prevent jarring too much. The honey-comb is broken up in small pieces, and put into a receptacle in a room sheltered from bees and sun. A hole at the bottom allows the honey to flow out. This is received in another receptacle, of earthenware, and in this stored away to find its way into the market. The Maltese honey is sold at 6 or 7 pence a pound, while the Sicilian honey, which is worked into confectionery, brings only half the price.

The swarming season is about the month of April; and, according to their notion, "the drones, which they suppose to be hatched out of the queen-cells, compel the swarm to leave the mother hive, and are then either dissipated by the wind or otherwise killed by the bees. Should the bees not kill the drones (which they confound with queens), the swarm is liable to fly off again. The leaders they call 'flowers' (drone-queens) are not the mothers. As soon as the swarm is settled they start building comb, and filling the cells with honey and water. Out of this mixture the young bees issue; but the water must be as clear as crystal, otherwise no bees will hatch out." The bees seem to be great swarmers, for they have from three to five swarms per hive, in good seasons. When any

honey is wanting, they feed the bees by putting shallow earthenware plates, filled with honey and syrup, in the back part of the hive.

The hornets are also among the enemies, although it is twenty years since they have been strong enough to destroy any hives. They destroy the hornets by simply burning the nests where they find them. The early rains of this season have destroyed them altogether. Moths are a great nuisance too; but as the natives keep only a few hives, which are closed by only a flat stone at the back, they can at any time look in, without disturbing the bees. Those I saw were very quiet. We did not meddle with them any more than to look at them and take a few bees out of the foremost. The natives are very much afraid, too, of the "evil eye." Some persons are not allowed to look into the interior at all, as the effect of their looking at them would very soon destroy the hive. The death-head moth, too, takes honey, but is killed by the bees as soon as it contrives to enter the hive.

A barren rock, as many call Malta, it is still wonderful how many vegetables are raised, and, indeed, good ones too. They are very laborious, those Maltese which have to depend entirely on commerce. It being a well-situated island in the Mediterranean, between Sicily and Africa, it has a very splendid harbor, or, rather, a number of harbors, into which a number of steamers are continually going and coming, principally as a coaling station, besides the many men-of-war which are either stationed here or call here on their Mediterranean tour.

AN OLD TRADITION CONCERNING PAUL AND THE VIPER.

The Maltese are very religious and superstitious. All the country is covered with churches dedicated to as many saints. They always uncover their heads when passing by a church or shrine. The church of St. John, where all the Grand Masters and Knights of the Templars are buried, is one of the finest and richest churches I have ever seen. St. Paul has many churches, chapels, grottoes, and bays here, in commemoration of the great apostle's shipwreck on the island. There is a curious tradition among the islanders respecting the viper that bit the apostle. They say, "When Paul the apostle was bitten by the viper, and shook it off into the fire without being molested, the inhabitants at once embraced Christianity on that account, and the venomous serpents were changed into harmless ones to this date." It is a fact now, that there are no venomous serpents here in Malta; but I believe there never have been any, as the island of Sicily is void of them. They are two blessed islands as regards this; for when we think how many persons are killed in India yearly by serpents, this may be called a very happy place; nevertheless, I am happy to leave it to-day and bid Malta adieu, feeling a little bit with Lord Byron, who tasted the disagreements of Malta, and very especially, it seems, its quarantine, as he says in his "Farewell to Malta."

P. J. BALDENSBERGER.

Valletta, Malta, Nov. 5, 1890.

OUT-APIARIES.

OVERSTOCKING AN APIARY; HOW MANY BEES CAN WE KEEP IN ONE LOCATION WITH PROFIT? SOME VALUABLE SUGGESTIONS FROM E. FRANCE.

This subject has been worked over time and again; still, what do we know about it? I am aware that there is a considerable number who are thinking of starting an out-apiary the coming spring, as their home apiary is becoming

overstocked, or, at least, they think so. Now, so much depends on the amount of honey-producing plants on a given location, it is hard for one to lay down any set rules as to how many bees we can keep, or how far apart we must locate our apiaries to obtain the best results. In good seasons we may be able to get good returns from a crowded pasture. But seasons like the last tell very plainly when we are overstocked—that is, for a poor season.

□ I have taken pains to make a correct diagram of the territory that we occupy with our bees; and I must say that I was surprised myself when I saw the exact position of each yard. They are clustered together more than I had supposed. The accompanying diagram will show how they stand, and I will give some facts and figures that will make quite an interesting study about setting out out-apiaries and overstocking our pasture. Of course, it is impossible to locate a set of out-apiaries just so far from the home apiary, in a circle, each one in its proper place, just as nicely as we could make it on paper. We have to take such places as we can get, and many of the places that we can get won't do at all, for some reason or other; and when you have six or eight yards planted you will be likely to find, as in our case, some of them badly crowded—too much so for profit.

FRANCE'S OUT-APIARIES.

The circles in the diagram are three miles each, or $1\frac{1}{2}$ miles from center to the outside, which is a very short distance for a bee to go in search of honey. If the bees fly three or four miles, as I think they do in poor seasons, it is plain to see how it works in a poor season. The outside apiaries may be getting a fair living, while the inside yards are nearly starving. In first-class seasons, when honey is plentiful everywhere, and very few bees go over one mile, there is enough for all. I here give the number of bees in each yard this spring, the amount of honey taken, and the amount of feeding this fall to put the bees in trim for winter.

Now, notice the Kliebenstein yard, how it is located, away by itself, as for distance, from other yards. It has a great advantage; and then there is plenty of basswood all around it. It has no bees belonging to other parties on its territory. It gave the most honey, no feeding, and is in the best condition of any yard for winter stores.

We will now notice the Atkinson yard. It is pretty well hemmed in on the north and east sides by the other yards, but it has an unlimited field on the west, of good pasture. We took but little honey there, but it is in good condition for winter, without feeding.

Now, away over on the east side we have the Waters yard. It is two miles from basswood, but a splendid white-clover range—plenty of basswood two miles north and east. This yard gave some honey, and required no feeding for winter.

Then there are the Cravin and the Gunlauch yards, each 90 colonies in spring, only $1\frac{1}{2}$ miles apart—too close, with very little basswood north of them. Both of these yards were fed more honey than we took from them. There were a few acres of buckwheat near them that helped them some. The Jones yard did fairly well, considering its surroundings. It had the least number of bees, an abundance of basswood near, and then had eleven acres of buckwheat just over the fence.

We will now notice the home yard. There were 105 colonies. The Jones yard is rather too close. Then there is an apiary of 20 colonies a little over half a mile east, at a point marked Beihls; another apiary $1\frac{1}{2}$ miles east, 30 colonies, marked Nails; another apiary southeast, marked W, about 40 colonies. Another apiary still further to the east, and a little to the north, marked W, about 40 colonies. So you see the home-yard territory is overstocked the worst of all, and had to be fed 360 lbs. more than was taken from them. The home yard has the best clover field of any, but basswood is scarce within two miles. In looking at the diagram, one not acquainted with the ground would likely ask, "Why don't you use that open space southeast of the home yard?" It is all prairie land. Corn and oats don't yield much honey.

We will now just look back to the record of a year of plenty, 1886, and see how the yards averaged up then.

Now, friends, you have the figures and the map of the ground that our bees are on. Study it for yourselves. But if you plant out-aparies, don't put them less than five miles apart if you can help it. If you are going to keep help at the separate yards, to run the bees, six miles apart is near enough; then, if the pasture is good, you can keep from 100 to 150 colonies in each place. If you go from home with your help every day, then you want to gauge the number of colonies so as to work one whole yard in one day; or if you have but three or four apiaries in all, you will have time to work two days in each. But don't go over the roads for less than a full day's work when you get there; and remember, when you are locating an apiary, that, when you are hitched up and on the road, one or two miles further travel will pay you better than to crowd your pasture. Don't overstock your ground. E. FRANCE.

Platteville, Wis., Nov., 1889.

Friend F., you have given us an exceedingly valuable communication from experience, and your diagram is a study. Your tables are astonishing, and yet it is not more than we should expect; and the effect of overlapping apiaries, in the amount of honey secured, and the amount of feeding required, is very marked. In a poor season, then, it is better to have the colonies further apart. When there is a good flow of nectar, it does not matter if they are nearer together. The suggestions in your concluding paragraph are excellent, and will bear reading several times. Yes, when you are hitched up and on the road, one or two miles further travel pays a great deal better than to crowd pasture. It would pay us all to study our territory carefully, as you have done; and I hope some of our other out-apiary bee-keepers will take the pains to make a diagram and see what they learn from it.

FUNGUS GROWTHS IN INSECTS.

PROF. COOK CORRECTS A SENSATIONAL MISSTATEMENT.

Friend Root:—You ask me to comment upon the illustrated article headed "Wooden Caterpillar," to be found in the *Scientific American*, Sept. 27, 1890, page 201. I gladly do so, as it gives a good chance to illustrate how love of the sensational leads to false conclusions and erroneous statements.

The article, in brief, is this: An insect, the oweto, of New Zealand, commences a caterpillar, and ends a vegetable. To quote, "This is a vegetable caterpillar—called by naturalists, *Hipitilis virescens*. It is a perfect caterpillar, and when full grown measures three and one-half inches long." To quote again: "Until it is full grown, it conducts itself very much like any other insect; but when fully grown it undergoes a wonderful change. For some inexplicable (sic) reason the spore of a fungus fixes itself directly on its neck, takes root, and grows like a diminutive bullrush, from six to ten inches high, without leaves, and with a dark-brown head."

The caterpillar had previously entered the earth. Many caterpillars—all of the families of

noctuidæ and *geometridæ*—do this to pupate. The fungus grows up to the surface of the earth, and a little above. The root grows into the caterpillar, which it exactly fills in every part, and, without altering its form in any respect, substitutes vegetable for animal tissue. Then both die, and become very hard, but with no change of form. "The thing is then a wooden caterpillar."

"Where the oweto is found, specimens are easily obtained. It is light green when alive, and the Maoris eat it in its soft state. When dry they powder it for use in tattooing." So far this account is not really untrue, but is misleading. One would infer that the animal really transformed into a vegetable. In reality it transforms only as a vegetable transforms into a man when we eat cabbage. The fungus grows from the caterpillar, and obtains its nourishment by taking the substance of the insect. But what is left is no more the insect than the stone of the fossil-fish is the fish itself. But the close of the article is wholly untrue. It is stated that the caterpillar and fungus were made for each other. Yes, just as the lion and the deer which it kills and eats were made for each other. I imagine that the deer tribe would object to the statement, just as Iween the caterpillar that becomes a victim to the fungus would do, could it speak; just as we would object to the remark that we and microbes are made for each other, because microbes kill some people through consumption.

Again, the article states that the caterpillar never exists without the fungus (?), or the fungus without the caterpillar. This is not only untrue, but utterly absurd. If every caterpillar is killed by the fungus, what keeps up the species? The very fact of the existence of the caterpillars shows that some are not attacked and killed by the fungus, but develop into moths which lay eggs and produce more caterpillars. Suppose cholera were always fatal; how absurd it would be to say that people were made for the cholera microbe, and never existed without it! I am not sure that the reverse, in case of this New Zealand fungus and insect, is not true, but I presume it is not. It may be that this special fungus must have for its life and growth this special caterpillar, and will grow in no other soil, if we may so speak; but I doubt whether such is the case. While possibly it can grow only in this species, more likely it will develop from others as well. I send a copy of the figure from the *Scientific American*, that the readers may see how the fungus and victimized caterpillar appear.

The explanation of this is easy. The fungus develops, at the brown enlargement, many spores, which take the place of the seeds in these lower vegetables, like puff-balls—the fumes of which are these spores, and like the mushrooms or toadstools. These spores, when they lodge in suitable soil, and are watered by the right conditions, grow. Our toadstools like a damp rich soil. This fungus takes to the tissues of a caterpillar. In its growth it appropriates the substance of the insect, which, as a consequence, dies, so

THE WOODEN CATERPILLAR.

the fungus is a terrible insecticide. Were all the caterpillars attacked, as the article states, all would die and there would be no more food for the fungi. In case they grew on this insect only, as stated in the article, they too would all likewise perish.

We have a case exactly like this, not uncommon here. The common and very destructive white grub, *Lachnosterna fusca*, larva, of the common

May or June beetles—often called June bug—is frequently attacked—see figure—by a fungus. This fungus is fatal to the grub, and we may well wish it to become more common, as we should like to see all its hosts—the grubs—destroyed. But, like all vegetation, these fungi must have suitable conditions in which to thrive, and so they often fail either to find the grubs or else to develop when the spore is once planted.

A. J. Cook.

Agricultural College, Mich., Oct. 15, 1890.

I am very glad indeed to have such able authority as friend Cook come forward and tell us that a statement like the above is not only an untruth, but an absurdity. The world is full of people who are ready to grasp and take in as truth such misleading statements, especially when they come through such a journal as the *Scientific American*. When the thing first came under my eye, I pronounced it at once as absurd as the popular newspaper yarn of a year or two ago, that hens' eggs were being manufactured, so real as to defy detection; and when somebody else a little later said that "these eggs would hatch chickens, but the chickens did not have any feathers on," a few were ready to swallow this down as a real achievement of the present age. Perhaps these latter were younger people who did not give the matter very much thought. We hope the *Scientific American* will be fair enough to its readers to correct the untruth which they have perhaps inadvertently let pass in their journal. The *Scientific American* deserves more credit, perhaps, than any other paper published, for promptly putting down any blunders in mechanics or machinery—the Keeley motor, for instance. But it requires an editor of more than human wisdom and energy to detect like frauds in kindred industries. Perhaps this is why foolish statements in regard to manufactured honey have obtained space in so many journals that are sound and accurate in their own line of work.

LOCAL CONVENTIONS.

A MODEL ASSOCIATION IN E. FRANCE'S NEIGHBORHOOD.

The Southwestern Wisconsin Bee-keepers' convention was held in the apiary rooms of Mr. E. France, Platteville, Wis., Oct. 8, 1890. A large number was added to the membership, including some from Dubuque Co., Iowa, and Darlington, Wis. On account of so many papers read before the convention, and the dis-

SOUTHWESTERN WISCONSIN BEE-KEEPERS' ASSOCIATION, HELD AT PLATTEVILLE, OCT. 8, 1900.

cussions that followed, for want of time questions had to be somewhat limited.

The association has now become large enough, and interesting enough so that the probability is it will soon require two days for its conventions instead of one, as heretofore. Had there not been an evening session some of the papers, discussions, and questions would have had to be laid over. A gathering of the assemblage was soon arranged, when the artist took two shots, and I am happy to present you a good view of the convention.

The cordial entertainment and hospitality extended by Mr. France and family is simply a matter far beyond any expectations; and it is probably a question whether any class of people but bee-keepers could excel in such a welcome as was enjoyed there. Mr. France has a cabinet of collections that is well worth the time and trouble to go and see.

The enjoyment of the meeting, so many being there, and the new acquaintances made, gave us no time to indulge in any bad grammar about the drenching torrents that poured down along the road to our homes. Such gatherings are not only a gain of knowledge, but they promote benevolence, charity, and good will toward all men; and if there was any exception to the above, it is to be regretted by the majority. The next convention, if not otherwise changed, will be held in Lancaster, Grant Co., Wis., of which due notice will be given.

The following is the list of names corresponding to the numbers above:

1. James Armont, Argyle.
2. John Hohmann, Durango, Iowa.
3. Mrs. N. E. France, Platteville.
4. Frankie France, Platteville.
5. N. E. France, Platteville.
6. Miss Ida Smith, Darlington.
7. Mrs. E. Pike, Boscobel.
8. Mrs. W. Bailie, Lancaster.
9. Mrs. H. Gilmore, Georgetown.
10. Mrs. M. M. Rice, Boscobel.
11. Mrs. R. K. Jones, Boscobel.
12. Ben. Rice, Boscobel.
13. H. Evans, Wauzeka.
14. E. France, Platteville.
15. E. Pike, Boscobel.
16. Mrs. R. D. Wilson, Platteville.
17. Mrs. H. C. Gleason, Lancaster.
18. Mrs. E. France, Platteville.
19. William Kaup, Cuba City.
20. R. L. Clark, Georgetown.
21. John Clark, Potosi.
22. Joseph Patzner, Potosi.
23. Charles Patzner, Potosi.
24. Henry Franke, Potosi.
25. G. W. Kendall, Boscobel.
26. R. D. Wilson, Platteville.
27. John Kemp, Jamestown.
28. R. K. Jones, Boscobel.
29. L. C. Fuller, Dubuque, Iowa.
30. W. H. Prideaux, Bloomington.
31. William Seeman, Boscobel.
32. James Harker, Argyle.
33. W. J. Bailie, Lancaster.
34. H. C. Gleason, Lancaster.
35. Austin Dexter, Boscobel.
36. M. M. Rice, Boscobel.
37. Henry Clark, Potosi.
38. John Kemp, Jamestown.
39. A. E. Cooley, Mt. Hope.
40. Mr. McLean, Platteville.
41. Delos Ricks, Boscobel.
42. George Fox, Big Patch.
43. H. C. Gilmore, Georgetown.
44. J. L. Lewis, Dubuque, Iowa.
45. James Wisdom, Boscobel.
46. J. W. Van Allen, Haney.
47. E. D. Peake, Jamestown.
48. Norman Clark, Potosi.
49. Seaman Howe, Platteville.
50. Martin Oudyn, Platteville.
51. Walter Pretts, Platteville.
52. Charles Nye, Jr., Platteville.

Boscobel, Wis., Oct. 13.

BENJ. S. RICE.

Here is what another says of it:

This was the poorest honey season in this section ever recorded. Average, 14 lbs. surplus, from 1655 colonies, as reported last meeting, Oct. 8, the date of the picture. No foul brood has ever been in our circle of members. We raise mostly extracted honey, and sell it in the West.

Platteville, Wis., Nov., 1890.

N. E. FRANCE.

We do not often give reports of local bee-associations; but along with it as above came a most magnificent photograph, and we could not resist the temptation to have the same reproduced in half-tone along with the report, so that our readers might enjoy it as we did. Why, it is inspiring to look upon those faces, and there are several of them that form quite a pleasant study. The natural poise of most of the figures, and the depth of expression of the faces, is most excellent. Of course, the reproduction of the above is not quite equal to the photograph, but you get nearly the effect by holding it a little further away than the average reading distance, say about 14 or 15 inches. There, now, notice particularly No. 14. Why, that is our old friend and veteran bee-keeper, and correspondent, E. France. Then in the foreground, No. 5, is Mr. N. E. France, and Master Frankie France beside him. The light was a little too strong for his eyes, evidently. I wonder if Miss No. 6, with the papers in her hand, was one of the essayists of the day. (The figure 6 does not show very plainly, but its location can not be mistaken, for it is between 5 and 7.) Miss Smith looks as if she might be equal to the occasion.

Right here I wish to urge upon all our readers the necessity of forming, if possible, local associations. Make some prominent bee-keeper its president, and some other one, equally prominent, it may be, its secretary. After that, organize a good rousing society, and see what a nice lot of people bee-keepers are. Oh, yes! after you are well organized, affiliate with the N. A. B. K. A. While we can not promise to publish reports of these local associations we will do all we can to encourage them. Let the good work go on.

E. R.

RAMBLE NO. 34.

AT THE RHODE ISLAND STATE FAIR.

The morning of September 22 found the Rambler at the railroad station, and ticketed for Providence, R. I.; and we were soon caught up by the train and hustled rapidly through the country. When we had become comfortably seated, and glanced at our neighbors, we found a very bright and active-looking young man attracting much attention. He was in charge of an officer of the law, manacled, and on his way to jail. Every one who came near was invited to look at his shining bracelets; and we never had presented to our vision a better object-lesson of cause and effect than when a bottle of liquor dropped from his side pocket, and, before restoring it, it was raised to his lips. The bottle and the shackles! Our thoughts ran into a train of moralizing, and the following lines from Pope came forcibly to mind:

Vice is a monster of such hideous mein,
As, to be hated, needs but to be seen;
But seen too oft, familiar with its face,
We first endure, then pity, then embrace.

This young man had entered into temptation, endured, pitied, embraced; and instead of living a loved and useful member of society, this one evil had made him a felon. Down with the traffic that fills our jails with so many wrecks! is the watchword of the Rambler. The last we saw of our neighbor, he was still showing his shackles to people on the street as he was hurried along to jail.

We whirled merrily along through the famous Hoosac Tunnel, and over a very winding way among the charming mountains that thus early began to be tinted here and there with the glowing autumn foliage. But few farmhouses were seen in these valleys; but we now and then came suddenly upon thriving villages. As we neared Worcester the country looked more thriving agriculturally, and a machinist of Worcester gave the Rambler much information about this portion of Massachusetts, and of Worcester in particular. One item of interest to bee-keepers is that here the first wire nails were manufactured in this country. The wire-works occupy a large space in the city, and employ 3700 men, and make an immense amount of wire and nails.

We arrived in Providence in the evening, and, after a night's rest at the Merchants' Exchange, we were ready for the duties of the day, and that was to attend the R. I. State Fair, held in Narragansett Park, and award the premiums in the bee and honey department.

We reported at the secretary's office; were shown where to find the sweet things, and proceeded to take a private inventory before we made our identity known. In our pre-ramble around the room we came across a young man by the name of Arthur C. Miller, and we revealed our identity. Bro. Miller then passed our identity around among the rest of the bee-keepers, and we all made a mutual exchange of identity by clapping hands. "Yes," said Mr. A. M. Cole, "I knew the Rambler as soon as he came in. That long-tailed coat, that umbrella, and that nose, looked so natural." We found not only a happy-looking crowd of bee-keepers, but a show of magnificent proportions; and we observed aloud to the friends, that Little Rhoda had a better display than the great Empire State ever had. There were nearly 100 entries, and about \$130 in premiums to award. The R. I. Experiment Station, in charge of Prof. Cushman, made a fine display which did not compete for premiums. Nearly every style of hive in use by prominent bee-keepers was in this display, and a novel feature was a large cage in

which a natural swarm was clustered on a branch of a tree, as in natural swarming.

The exhibit of comb and extracted honey proved by its quality and quantity that Rhode Island had not suffered much from a dearth of honey, and bee-keepers were accordingly feeling well. The various races of bees were represented in five full-sized glass hives and nine nuclei. The honey department was filled from morning until evening with a crowd of curious and interested visitors, and it was pronounced one of the features of the fair. From the exhibit of appliances we gleaned the fact that Rhode Island bee-keepers are as ingenious and progressive as any in the world. This down-east Yankee ingenuity was manifest in Mr. Miller's foundation-fastener, illustrated some time since in GLEANINGS, and which is gaining favor with bee-keepers; also Dr. Merchant's crate for comb honey, which we will try to describe in the future; also many articles in the exhibits of Mr. Thos. Pierce, A. M. Cole, Mr. Nivens, and Prof. Cushman, all showing ingenious labors for the elevation of our industry.

Aside from bee-keeping, the Rhode Island Fair was in every way a success. Every department was large and well filled; the weather was exceptionally fine, and 50,000 people were upon the grounds during the best days.

Narragansett Park is in the suburbs of Providence, a no mean city of about 130,000 population. A drive with Mr. Miller through a good share of it gave us a chance to see its many points of beauty and historic interest. Among the thousands of noble shade-trees in the city are a great number of English lindens, making excellent pasturage for city bees, of which there is quite a number. As those conversant with the history of Rhode Island are aware, this city was founded by that liberal-minded old man, Roger Williams. The people venerate his name to the present day; and his familiar greeting, "What cheer?" is found upon many places of business. After he had been buried 200 years, or, as a satirist expresses it, "until he became sufficiently dead," he was exhumed and buried in Roger Williams Park, where a splendid monument is erected to his memory. Upon digging to where the remains ought to have been, it was found that the roots of an apple-tree had completely absorbed the bones, and taken the form of a man. This curious root formation is now to be seen in the historic museum of the city. As several generations had eaten the fruit of the tree, the question was seriously asked, "Who ate Roger Williams?" Our satirist happily explains the situation:

But a jolly old apple-tree rooting around,
Seeking for phosphates under the ground,
Followed his back-bone all the way down,
And old Mrs. Williams's too.

What's bred in the bone, in the flesh will show;
What's bred in the root, the fruit will grow;
For two hundred years this fruit did grow,
Till posterity ate him up.

RAMBLER.

BEE-HIVES.

A SUBJECT THAT INTERESTS ALL BEE-KEEPERS.

In my bee-keeping experience I have found that I could generally get the attention of almost any bee-keeper when I had a new hive to exhibit, or was ready to discuss the hive-question. In fact, there is nothing connected with bee culture that will attract the attention of the average bee-keeper, or one that interests him more than a good bee-hive. Almost all bee-keepers are looking for something better in hives than what they have in use. In my day I have devised not far from twenty different

styles of bee-hives; and all but one were discarded after testing them a few seasons. There are several points I never lost sight of when trying to construct a practical bee-hive. Some of the points are these:

1. A proper brood-frame; 2. A hive suitable to winter bees successfully on the summer stands; 3. A hive so constructed that it can be set in the sun without protection all summer, and without danger of destruction of the combs or of roasting out the bees; 4. A hive so arranged that the largest amounts of both comb and extracted honey can be secured.

In some of the hives I have devised I could not combine all the desirable features here named. In my last attempt to construct a practical hive, and one suited to most classes of bee-keepers, I think I have combined all the best features. This hive is called the

BAY STATE CLOSED-END-FRAME HIVE.

I do not claim, by any means, that the Bay State is the ideal hive; but I do claim that it is good enough for any bee-keeper, and that it has but few if any objectionable features. I will describe some of the good points of the Bay State, and explain the illustrations in as few words as possible.

Fig. 1 shows the brood-chamber, which is merely eight closed-end frames, two side-boards, and two iron rods with thumb-nuts at each end. The frames rest on a bottom-board (illustrated in Fig. 5), and which is described further on. Resting on the brood-frames are four section-cases, each containing 24 1-lb. sections. This case, like the brood-chamber, is composed of frames or section-holders, as some bee-keepers call them. The brood frames, as well as the sections, are held firmly in position by being clamped between two side-boards through which runs an iron rod, which also has thumb-nuts at the ends. A description of the case will be given further on.

It will be seen in the illustration, that the cap which covers the section-cases is the same as used on the hive shown in Fig. 3.

FIG. 2.

FIG. 1.

BAY STATE HIVE DISSECTED AND READY FOR WINTER.

The Bay State hive is used in summer exactly as is shown in Fig. 3. Ninety-six sections can be used to good advantage on the hive at the same time. I have had colonies fill all in one good season—something which is considered a big thing here, when it is known that our honey season is of but a few weeks' duration, including both favorable and unfavorable weather.

Now a word about the way we manage the Bay State hive to get comb honey, and to use so many sections at one time. Of course, no sane bee-keeper would think of placing 96 empty sections on a hive at one time. One case of 24 sections is enough to start with, even with

the strongest colony. When one set of sections is pretty well filled, it is removed, reversed, and a new set of sections put on the hive, and the first set placed upon that, and so on till there are three or four sets of sections, or as many as the bees can work in at one time when tiered up. The passageways through the four cases are direct from the brood-chamber to the top sections. By this plan the empty sections are at all times nearest the brood. I believe that the sections can be put nearer the brood in the Bay State hive than in any other one now in use. This is a point I have tried to incorporate into all the hives I have devised.

FIG. 3.

FIG. 4.

BAY STATE HIVE FOR COMB OR EXTRACTED HONEY.

Another good point about this hive is, that it is not necessary to use any queen-excluder between the section-cases and the brood-chamber; and, furthermore, of the thousands of Bay State hives in use, no queen has ever been known to enter the sections and deposit eggs therein. Can this be said of any other hive in use? By reversing the sections when partly filled with honey, the bees attach the combs to all sides of the wood. This is a feature appreciated by all who find it necessary to ship honey a long distance to market. Bear in mind, that 24 sections are reversed at one time, and none can get out of place during the operation.

Here is another point about this section-case worthy of mention: The sections are all incased in wide frames, and it is impossible for the bees to get at them to soil them with propolis or by traveling over them. At the same time, every section is held in a perfectly square position.

Fig. 4 represents the Bay State hive as used for extracted honey. There are two sets of brood-frames—one over the other, with a queen-excluder between the two hives. On the top is used an ordinary honey-board, and then all is protected from sun and rain by a hive-cap, the same as seen in Fig. 4. A small stone, or weight of any sort, will prevent the wind from blowing the cap off. What little rain will reach the frames or section-case can do no harm.

Fig. 2 illustrates the hive as prepared for winter. By examining Fig. 5 (bottom-board) it will be seen that G G and F, are strips of wood upon which the brood-nest rests. These strips are $\frac{3}{8}$ of an inch thick. The outer case shuts down outside these strips, thereby completely excluding all water, and thus preventing the packing, when any is used, from becoming wet. As the entrance, E, E, is below the level of the bottom-board, and directly under the strips the frames rest on, no water can enter the hive there.

The sides of the winter case are but $\frac{3}{4}$ of an inch thick ($\frac{1}{2}$ board split), thus adding materially to the lightness of the hive. When complete in all its parts this hive weighs but 35 lbs.

Fig. 1 gives a good idea of the brood-chamber, section-case, etc. One frame is removed from the brood-nest to show the saw-kerf in the top-bar, for inserting foundation comb-guide, or for fastening full sheets of foundation when desirable to do so. The foundation is placed in the kerf, and then three one-inch wire nails are driven through the bar to hold the combs in place. The work is quickly done; and, when properly done, the foundation will hang perfectly true within the frame.

FIG. 5. BOTTOM-BOARD.

It will also be seen in illustration, Fig. 1, that one wide frame is removed from the section-case, thus showing the sections and the separators, which, it will be seen, run the full length of the case.

The Bay State hive has but 8 brood-frames, and a capacity of about two-thirds of a ten-frame L. hive. We have used this hive six seasons, and find it large enough for all practical purposes, and first-class in every respect. The brood-chamber is so compact and so well protected from the weather by the outer case, that colonies breed up rapidly and quickly in the spring. No hive can winter better on a summer stand.

The hive is so constructed that the closed-end frame or the L. frame can be used without any change to the bottom-board. Of course, the L. frames must be used in a box or case so that the frames can hang on rabbits.

Wenham, Mass., Dec. 1. HENRY ALLEY.

Our new Dovetailed hive with fixed frames has very many points similar in principle to the Bay State. You say that queens have never been known to enter the upper story of your hive. But, friend Alley, they will do so *sometimes* in all hives without perforated zinc, and yours would hardly be an exception. We have had no reports that queens went up into the upper story of our Dovetailed hive; but we have no doubt that there *are* instances when the queens have gone above. The outside case of your hive is, without doubt, a nice thing. Without knowing that you had such an arrangement we (that is, the younger part of the editorial staff) have been having a sort of leaning toward a case almost identically the same. Twenty-eight of our colonies have such cases over them for the winter, for experiment. As to how it will winter bees, you are silent in your article; but in your journal you have spoken highly in its praise.

THE ADVANTAGES OF THE CLOSED-END FRAME.

MR. L. C. AXTELL GIVES VALUABLE TESTIMONY.

As a bee-keeper here in the West, I have thought for several years I was nearly alone in the use of the closed-end brood-frame. But I was conscious of the fact that its merits here were not fully appreciated.

Now, the question has been raised, "What are its merits?" I will state how I came to use them, and why I adhere to them.

When our first swarm of bees was bought, which was in 1871, it was put into a box hive. The next year it gave two swarms, and probably 25 lbs. of honey, which we then thought was a prodigious crop. By mismanagement we wrecked one of the colonies. We were so wrought up by this loss that we talked with every person who had bees in our vicinity, and learned from them all they knew on the subject, and that was but precious little. We borrowed Langstroth's book, "The Hive and Honey-bee." Also hearing of M. Quinby's work, "Mysteries of Bee-keeping Explained," it was purchased and read. Soon we had on our table nearly all that was then printed about bees, and contents discussed. As yet we used only the box hive; but now it *must go*, and be replaced by a movable-frame hive.

After careful study we decided that the Quinby hive would be best for wintering purposes, so one was ordered, and all my first hives were made after that pattern. I think it was after using these hives two years that I happened to purchase a colony of bees in a hive with hanging frames—the Langstroth.

WHY THE CLOSED-END FRAMES HANDLE AS EASILY AS THE HANGING.

It occurred to me, "Now is the time to make a test of hives and frames." At the close of the season it summed up something like this: There was no difference in the amount of honey stored. Difference in hives did not figure much. Quinby hive cost most, but was best for outdoor wintering. The decision, therefore, must rest on the ease of manipulation of frames in the hive. I have always produced nearly all comb honey, and the surplus combs could be handled about as easily in one hive as in the other, so that did not count. But with my closed-end frames, during the honey-flow I could slip out one, two, or three brood-combs and replace them without disturbing the surplus receptacles; while to do the same with hanging frames, the surplus receptacle would have to be removed, then move at least two of the brood-frames in order to have room to take out the first frame; and in replacing I had to be much more careful than with closed-end frames. But if all brood-frames had to be handled, there was a still greater difference. In this case the supers would have to be removed from and replaced on each. But in using the closed-end frame, pry apart, leaving two, three, or even four stick together with propolis; lift them out of the hive, three or four together, and replace them in the hive in the same condition, push them close together; close the hive and the work is done. They are always properly spaced.

OBJECTIONS TO HANGING FRAMES.

With the hanging frame there is always the difficulty in getting out the first frame, so as not to kill bees or make them angry; then instead of handling three or four at a time, having to take out one by one. But putting back the frames is worst of all. They must be put in one by one; and when done as carefully as you may, perhaps there is not half room enough

for the last comb, and nothing to do, but re-space again; and when done—oh! too much room, and the work has to be done the third time. Have not all who use narrow frames had a similar experience many times?

THE ADVANTAGE OF REVERSING.

Another real advantage of the closed-end frame as I use it, is, that when the combs are out if any are not built down to the bottom-bar they are just as easily placed in the hive with the bottom-bar up; and if left so a few days, when honey is coming in freely they will be built solid to the bottom-bar, ready to be turned back with the top-bar up when the hive is opened again.

HOW TO PREPARE HIVES WITH CLOSED-END FRAMES FOR MOVING.

When hives are to be moved, put a rope around the hive, tighten it with a short stick, tack the entrance-blocks. Now all is solid, and ready to be placed on the cars, or carried on a wagon, if the weather is cool. If the weather is hot, of course there should be wire screen instead of roof on the hive.

OBJECTIONS TO THE QUINBY HOOP-IRON HOOKS.

The hoop-iron catches at bottom of the end-bar are on nearly all our frames; but in practice we hardly ever use them, as they get filled with propolis and wax. They work so easily without, simply shove them close together, then put the quilt or section-case on, and they will stay in position all right.

Were I now to begin keeping bees, with just the knowledge I now have, the full closed-end frame would be my choice. I am not sure but those using the hanging frame will find it to their advantage to make all their new frames with the upper half of the end-bars $1\frac{1}{2}$ inches, and thus in a measure secure the benefit of closed-end frames.

L. C. AXTELL.

Roseville, Ill., Dec. 2.

At the outset I will say that, when we speak of hanging frames we mean those *not* fixed. There, now, didn't I tell you so? and I am very glad that I have so good authority as Mr. Axtell in the West, and Mr. Elwood and Mr. Hoffman of the East, to bear me out in the fact that fixed frames can be handled just as rapidly (and I think a little more so) as the hanging frames. Mr. Axtell speaks from extended experience, in the production of many tons of honey; and every word he says in reference to the manipulation of closed-ends I saw verified in the apiaries of the East. It takes a good deal of hammering to make folks see the point; but at the risk of harping on one thing a good deal, I am going to say again, that, where the fixed-frame people gain time over those having frames not fixed, is in the fact that the latter can handle *four or five at a time*. They do not bother with handling a single frame if they want to get at the center of the brood-nest. They simply take out all the frames *en masse* up to the point of comb surface they wish to examine. In this way they can almost handle *hives* instead of *frames*. Read over again what Mr. A. says on this point.

Our friend speaks of the hooks on the bottoms of the old Quinby frame as being somewhat objectionable. Very likely they may be dispensed with. But in Mr. Elwood's apiaries these

hooks had neither propolis nor wax on them. In fact, the bees could not get access to them if they desired, without going clear to the outside of the hive to chink in the wax and propolis—a thing they would not be likely to do. But it is no more than fair to state that Mr. Elwood uses a modified Quinby system. As he is soon to present to our readers a series of articles, I will not speak further on this point.

Mr. Axtell alludes to the nuisance in removing supers to get at the lower frames in the L. hive. Why, on our regular hives, the Dove-tailed for instance, we have no trouble, because we lift a whole upper story off at once. Then we have perfect access to the brood-frames below. If the same were fixed, as, for instance, the Hoffman, we have all the advantages that our friend speaks of.

Friend A. mentions the advantages of an end-bar, widened at the top $1\frac{1}{2}$ inches, for ordinary hanging frames. This would make virtually the Hoffman. I think this one handles fully as easily as the closed-end, and for ordinary hanging-frame hives it is perhaps the best of the fixed frames.

Now, dear readers, if good and reliable witnesses say a thing is true, that either the Hoffman or closed-end frame is not an awkward implement to handle, but, on the contrary, possesses many decided advantages over the old hanging frame, let us not be so conservative as to block the wheels of progress. It may not be feasible or advisable for old bee-keepers of the hanging-frame school to change; but it may be an advantage for the new crop of bee-keepers coming on, to get started along the right track. Still further, as old combs are to be continually replaced in large yards more or less, it may be desirable for old bee-keepers to work in, for instance, the Hoffman, by degrees. Experimenting along in this way is quite safe, and is not likely to lead to any serious results, should this fixed-distance craze prove to be a mistake.

I hope some of our closed-end, or partially closed-frame friends, will not be so modest as to keep quiet much longer. There is friend E. T. Flanagan, who has used the Hoffman. I believe we have not heard from him very lately. Then there are several others. Let us have truth, wherever it may fall. We are glad to hear from Mr. L. C. Axtell. It is a good thing to get a glimpse of both sides of the house—husband and wife side, I mean. Both are capable bee-keepers.

E. R.

THE HIVE FOR THE HONEY-PRODUCER— SINGLE OR DOUBLE WALL?

A REVIEW OF THE HIVE-QUESTION.

As a great many bee-keepers will soon be thinking about the hive they will use next season, a few words on this subject may not be out of place now. Perhaps no one will dispute the

fact, that the mass of bee-keepers who are keeping bees for profit demand a cheap, simple, practical hive. Shall this be a single-walled or a chaff hive? is a question not so easy to decide. If the single-walled will do, then we need look no further than the Dovetailed; but this must be protected, if wintered outdoors; or, if wintered in the cellar, spring protection is needed. It has been suggested by Ernest and several others, that an outside case be made for winter; but A. I. Root predicts that such cases will never come into general use, and I think he is right.

Well, what about chaff hives? I think this: The heavy, expensive chaff hive, with walls five and six inches thick, requiring two men to move around, never has been used to any great extent by our large honey-producers, and is too expensive and bulky to ever become popular with the mass of bee-keepers. It seems to me that such thick walls are worse than useless, as they prevent the warmth of the sun from reaching the bees, which I consider quite an advantage, especially in the spring, after brood-rearing has commenced. I also consider a double bottom useless, for, if the hive stands as near the ground as it should, the packing will become damp.

I have been using a hive several years that I think would suit the class of bee-keepers spoken of on page 697; i. e., those who produce comb honey, and winter on the summer stand. This is an eight-frame chaff hive, arranged for two inches of chaff around the lower story; but I have used the most of these without chaff, and can see no difference in wintering. The hive is made from light lumber; and with a handle on each end it is almost as easy to move as a single-walled hive. It has a side-opening in the upper story, which is very convenient for taking off surplus or working in the brood-apartment. With thick top-bars and a T-tin super containing a follower to key up the sections, I consider this the most practical, economical, general-purpose hive in use. G. H. KIRKPATRICK.

Union City, Ind., Nov. 29.

Friend K., you strike a chord that affects most of us. We want an all-purpose hive. The regular chaff hive which we have been selling is rather large and cumbersome to move about, and, besides, expensive. What we want, I think, is a single-walled hive so arranged that it can be converted into a winter hive for outdoors with small expense, when so desired. If an outside case will winter bees successfully in most latitudes, then I think its ultimate adoption is assured, by the outdoor-wintering class. The one thing in the way has been this: If such a case shall require packing, it will make it objectionable. But you say that you can see no difference between hives packed and those not packed, so far as wintering is concerned. That is just the information we are after. Your chaff hive may be small and compact, but it can not be as small and compact as a single-walled hive. For those who desire to winter outdoors, they want outside protection of some kind to put around the small hives. Now, then, when they come to move an apiary all they have got to do is to move the small hives, and, in the fall, cart in a large hay-rack wagon, say, the large outside cases to the yard. See remarks on this point from R. F. Holtermann, on the next page. E. R.

BEE-HIVES, LARGE OR SMALL.

GOOD ARGUMENTS FOR LARGE HIVES.

In reading the magazines devoted to bee-keeping I often meet with articles describing experiences with bee-keepers with their hives differing from my own. In 1861 I adopted the Kidder hive. The inside measurement of its frame is 11 by 13 inches. The Kidder is a double hive—or, rather, two hives in one. The inner part holds eight frames; and the outer part, when used by itself, holds eleven frames. The same frame fits both, running the longest way in the smaller part, and the shortest way in the larger part.

I constructed 50 of these hives, and used them as double hives until they were full of bees. Then I separated the hives, using each part as a hive. The first difference between them that I noted was that the small hives sent out the most swarms, and not very large ones. They were slow to work in boxes, and would often swarm a second time before doing so. The large hives, on the contrary, would send out much larger swarms, which would go immediately into the surplus apartments, and, as a rule, gave much larger returns for the care bestowed upon them. This comparison I have carried on for twenty-five years; and the result is, that I am now using the small hives for kindling-wood, having destroyed fifty of them for that purpose.

I have made some changes in the method of using my hive, which can be applied to any hive. I have changed the entrance so that the frames run across it. This enables me to put in one or more frames, and have a nucleus hive, with but one division-board, or adapt the size of the hive to the capacity of the swarm, up to the full hive. With frames running the other way, two division-boards would be required to accomplish this. I like this hive well enough; but if I were going into the business anew I would use the Langstroth or Simplicity, because they are more generally used; and if you wish to sell, they are more likely to suit your customer. I would adapt any hive to this method of using the division-board. The bees do not seem to know or care whether they enter the hive at the end of the frames or at the side. They deposit most of the pollen in the frames next to the entrance; and if you do not like the bees to have access to the pollen in the winter, you can easily remove these frames and substitute frames of honey. My largest hives, as a rule, have the most bees, breed faster in the spring, put in more surplus honey, swarm less and winter better, than the smaller hives.

CAGING QUEENS TO PREVENT SWARMING.

Some cage their queens during the honey-flow, for fear they will have too many consumers to eat the honey after the honey season is over. My experience is, that a large swarm is almost sure to store more honey than they eat, while a small one might fail in this respect. Then if you have a "giantess" for a queen, a large hive will give her a chance to do for you the best she can. A poor queen is of little or no value except to hold the swarm until a better one can be raised. Queens over two years old are, as a rule, not as good as younger ones.

Give me a good-sized hive and a young and vigorous queen, and I shall expect my share of the honey if there is any in the blossoms.

L. C. WHITING.

Saginaw, East Side, Mich., Dec. 1.

We are very glad indeed to see our old friend Whiting contributing again to GLEANINGS. His experience with large hives agrees remark-

ably with that of friend France in many respects. My experience with large colonies agrees with the above. The powerful ones get honey when ordinary colonies seem to be losing, and yet I could never quite fully understand it either.

THE OUTER WINTER CASE.

SOME OF ITS ADVANTAGES.

I should like to give a few reasons why the outside protecting case for the Dovetailed hive, as proposed by E. R. Root, will be superior to the old chaff hive. It will be cheaper and less complicated. The shell can be lifted from the hive, and then the hive manipulated as a single-walled hive in summer. I say, in *summer*; for should I take them they would certainly be retained for shading purposes during the heat of the summer. Of course, the chaff hive answers the same purpose; but the difference is in hauling bees, shipping, carrying into the apiary, etc. There is a wide difference between the two. In shipping, the shells (or cases) if desired can be shipped ahead by freight, and the bees expressed. In hauling, the experienced apiarist can take a full load of bees and send an inexperienced man the following day with the shells. In fact, I can not help thinking that a more valuable thing has been designed that we at first have given credit for. In summer we place this shell about the hive, say propped up on four posts, so that the shell has the same relative position to the upper story that it had during winter. With the body in that way, we secure a current of air between the hive and shell, and have the sun effectually broken.

PROPOLIZED QUILTS.

I lately saw an excellent idea in regard to propolis. Geo. Morris, Stony Point, scrapes the propolis from the frames and quilts; and after heating it he brushes it on the quilts he is about to put on the hives. The result is, the bees will not bring in nearly so much propolis, and thinner material can be used for quilts, as the bees will not gnaw through them. I last saw them Sept. 1. They were then not even attached to the top-bars. How they are now, I do not know. R. F. HOLTERMANN.

Romney, Ont., Nov. 17.

The outside winter case is an old idea; but the mere fact of its being old may not alter its value to the modified bee-keeping of to-day. Yes, there is quite a point for such protection; viz., sending the outside cases to the apiary with cheap help, either before or after the bees in the small hives are moved. It is not feasible to move bees in large chaff hives. Mr. Manum does not do it.

THE NORTH AMERICAN BEE-KEEPERS' ASSOCIATION.

DR. MILLER TALKS TO US ABOUT IT.

It isn't so many years since the senior editor of GLEANINGS not only stayed away from beekeepers' meetings, but, I think, advised others to do so. "A wise man seldom changes his mind: a fool, never." Friend Root is not a fool, so in this case he has changed his mind, and now wants some one to punch him up if he should try to stay away from another meeting of the North American. Good!

Some pretty severe strictures upon the course of that same North American moves me to ask space in GLEANINGS to say some words about it. An association of the kind is needed for the best interests of bee-keepers; and until such association is just what it ought to be, it is right and proper that it be discussed. Now is the time to begin such discussion, without waiting to take up time at the convention at Albany. So, friends, if you see something that needs mending in the ways of the association, let us have it in print, and have it soon, so that any thing that needs it may be mended if possible before the next meeting.

One point that has come in for its full share of criticism is the matter of obtaining reduced railroad rates to the convention at Keokuk. To get the best attendance we need low railroad fares always; and this year especially, when crops were so poor, we should have had reduced rates to Keokuk. Some one may suggest that, as I was a member of the Executive Committee, I am condemning myself. I was only treasurer, a sort of silent partner, and it would have been out of place for me to put myself forward and attempt to do the work of the president and secretary. Besides, I did urge the matter. Really, it is the secretary who usually attends to things of this sort; and the only thing left to be done now, is to pass a vote of severe censure upon Secretary C. P. Dadant for culpable neglect of duty—a neglect for which those who attended had to pay in dollars and cents, and which prevented some from attending.

But, hold on—hold on! In stating what *ought* to be done, it is important, in many cases, along with the *what* to give the *how*. And before we call down too many anathemas upon the devoted head of the poor secretary, it may be well for some one to rise and tell how he could have got reduced rates. If I am rightly informed, application was made, at an early date, to the railroads for reduced rates, to which they replied that it was too early, and that the matter could not even be considered by them. After waiting months and using what leverage could be brought to bear, the secretary finally got an answer. The railroads would grant no favors. I don't know what else the secretary could have done. Do you? If you do, tell it; and if you know any thing that will help in the future, tell it; for that is of more consequence than the past.

At Keokuk it was urged that a place should be selected to which we could get reduced rates on account of something else than our meeting, and that was the weighty argument in favor of Albany. If the association becomes sufficiently large, I believe we may be able to command concessions from the railroads without any begging.

Now, friends, instead of standing off and throwing stones, let us come together and talk it over—in print. If there are wrongs, tell what they are; and above all, tell *how* they are to be righted. Some think the association should be effective in bringing up the price of honey to accord with its scarcity. Just the thing to suit me—if it can do so.

I am satisfied that good will come of discussion. Some mistakes will be shown and corrected. Other things will be shown impossible of amendment; and knowing this we will endure them the more patiently.

One of the worst things about the association has been the flimsy character of its organization, as mentioned by Pres. Taylor. The movement for its incorporation is a long step in the right direction. Some of our editors are making a push to secure funds from life-members, and use up the money. The secretary

has evidently been doing some thinking about this, and thinks we ought to "consider the matter of placing the funds that may hereafter be collected from affiliation and from life-memberships in some safe interest-bearing bonds, so that the capital that may be thus paid in be not squandered." He says: "Annual memberships ought to pay annual expenses, and the interest of the capital ought to furnish prizes and medals." There would be an element of permanence about this which is desirable. I confess, however, that I would just as soon see all the money in the treasury cleaned out every year, or nearly so, if some plan could be devised by which equal permanence could be secured. The affiliation fees will come annually, just as much as the fees from annual members.

Stability of membership is a desideratum never yet reached. We are, perhaps, behind all the world in this respect. Can not some means be devised by which a permanent membership of four or five hundred can be secured? It is done elsewhere, I think. Are the obstacles insuperable here?

Is there any sufficient reason why the "Beekeepers' Union" can not be merged into the N. A. B. K. A.? That seems somewhat permanent. Why not both together? C. C. MILLER.
Marengo, Ill., Nov. 26.

All right, friend M. We second all you say. In regard to reduced rates for the convention, we tried our hand at it here, and received courteous replies to the effect that the number in attendance was too small to admit of the reductions we desired. I guess this is so, friends; and therefore the only thing to be done is to get the membership up to 400 or 500, as you suggested.

ARTESIAN WELLS.

THE FLOWING WELLS OF FLORIDA.

Mr. Root:—You seem interested in flowing wells, so perhaps a few words on that subject will be acceptable. Along this, the east coast of Florida, there are hundreds of flowing wells. Most of the houses, even in the towns, have their well of water flowing, and no trouble about pumping. A pipe varying from one to four inches in diameter is driven down until it strikes rock, when a drill is put inside of the pipe, and the rock drilled until water is struck. Sometimes no rock is struck until nearly to water, and the pipe with a point is driven through to the water. There are several layers of rock with sand, etc., between them; and the more layers the pipe or drill penetrates after reaching the flow, the larger the flow of water, though I believe the water rises no higher.

The water is struck about 60 to 90 ft. below the surface, and rises, I believe, 16 ft. above sea-level, and usually fills the pipe. A three or four inch pipe, with a strong flow, makes quite a stream of water, and makes it very convenient, as the water may be piped into the house, used for irrigating, etc. As a well with an inch or 1½-inch pipe costs only \$50 or \$60, they are not very expensive. By using a ram, the water may be forced as high as is wished. The water is hard, and is said to be impregnated with sulphur. At this place, next to the ocean, there is a peninsula nearly half a mile wide; then the Halifax River more than a mile wide; then the mainland. Wells on the peninsula, or driven in the river, flow just the same as on the mainland. It looks strange to see fresh water bubbling up out of a pipe, and the surrounding water salt. The quality of water varies con-

siderably in different wells. In some the sulphur is so strong as to be very offensive to some people; in others, little or none can be detected. The temperature also varies considerably. Daytona, five miles north of this place, is called the "Fountain City," from the number of wells it contains.

JOHN B. CASE.
Port Orange, Fla., Nov. 24.

ANOTHER ZINC-PERFORATOR.

A SMALL FOOT-POWER MACHINE.

Find inclosed a photograph of a foot-power punch I have had made, which perforates four holes at one stroke. The whole thing is made of iron and steel, and is substantial and perfect. The die is held in a chuck, and regulated by four set-screws, and the teeth to the punch are of different lengths, and shaped so as to "shear,"

REESE'S FOOT-POWER ZINC-PERFORATOR.

which makes it cut easily, and with very little power. I inclose a sample of zinc, cut by my machine on the margin of a piece which came from you, I think, some time ago. The machine was made by W. T. Clifford, Wellington, O., who, I think, is to be congratulated. I want to have this machine on exhibition at the World's Fair, Chicago, 1892.

J. S. REESE.

Winchester, Ky., Nov. 18.

We take pleasure in presenting in half-tone the photograph presented by Mr. Reese. The appearance of the machine indicates that it was gotten up by a mechanic; in fact, the punches and dies are so accurately fitted that it perforated perfectly a piece of tissue paper which is before us. The samples of zinc were received;

and, if we were to judge, they are fully equal to the beautiful work done by Dr. Tinker. This, however, is a foot-power machine, and is limited to the perforation of only four holes at a time. The machine we use is run by power, and cuts 64 holes at one "chank." Of course, this will make foot-power work more expensive, if time is worth any thing. This not only reduces the power required but makes nicer work. You will notice that we are giving our friend a little free advertising, but we are glad to encourage a little original genius once in a while in this way.

DAYLIGHT BREAKING IN THE HONEY BUSINESS.

IMPORTANCE OF GRADING.

Mr. Root:—We had some of that dark alfalfa extracted. Half that you sent us was that color. The sample sent us was nice and white. After receiving it we did not write you about it, as we thought you would doubt our word. We sold some to a druggist here in this city. He always writes to send him honey of our own production. We answered him, saying we had some from another State, and quoted him prices. He ordered, but has not yet settled. He has always been a good customer. We hate to go and present a bill for the honey, as we know he was not pleased with it. Some we sold to called it New Orleans molasses.

We also bought some honey in this State, called clover. After receiving we found it to taste pretty strongly of buckwheat. Being disgusted with the above purchases we went to New York and ordered some extracted honey that was white. They had none but California. We took that. We asked them to sample each can before shipment. They said that the quality was marked on the outside of each can. When we received this a large share was dark and not of first quality. We are now thinking of not buying a single pound more. We are disgusted with the whole business. We have had only one shipment that was as represented, and that comes from—I am going to mention his name, for those who sell good goods ought to be known—C. H. Stordock, Durand, Ill. His honey is *every way* first class.

Always keep it before the bee-keeper about careful grading. I am firmly convinced that a large trade could be worked up for extracted for table use, and at good paying prices. All it needs is a first-class article. F. A. SALISBURY.
Syracuse, N. Y., Dec. 3.

Perhaps some of the friends wonder at the heading to friend Salisbury's communication above. It is simply because friend S. has begun to talk right out in meeting about his troubles. He is most surely right—that a big trade can be built up if we can be sure of getting honey that is according to sample and according to label. Now, while it may not be best to publish the names of all the friends who have not heretofore been conscientious, it certainly will be safe and right to put the good men right in print; and may be we can decrease the former and increase the latter by so doing. Friend S., neither you nor anybody else need be backward about complaining of things that are not as they should be. Fix it

up with your customer the best you can, and make out your bill; and if we can not trace it to the man who shipped us the honey, it is right and proper for us to bear the loss. Now, the main point is, can you give us the name or initials on the can or cans that contained the dark alfalfa honey?

GRAHAM BREAD.

WHY IS IT NOT MORE USED? ETC.

The facts are, the world is wedded to its daily habit of life. It insists on using bread made from flour which has been robbed of much of its best food elements by the bolting. Another objection which I once knew a lady to offer against the use of graham flour, was, that among her acquaintances those who used it were *infidels*! You have already treated us to a column about

"OUR DAILY BREAD."

In his "Science of Human Life," Dr. Graham devoted 40 pages to bread-making. Good bread is something that can't be *overdone*—unless left too long in a hot oven.

Now about those gems made of flour and water and a little baking-powder. Of course, they are nice. We often have them for a change. My wife calls them "popovers." They are certainly delicious, and, with butter, honey, and a glass of rich milk, are too good to—talk about!

But for every day in the year, gems made of absolutely nothing but flour (graham) and water, and a pinch of salt, in sweetness, delicious flavor, as well as hygienic elements, are perfection. Much importance attaches to the quality of the flour. That which is made at Akron, and sold by grocers, is not so good. It should be the entire product of clean wheat, ground and not bolted. It has *not* good keeping qualities, and should be obtained fresh from the mill.

TO MAKE GRAHAM GEMS.

Take of graham flour, quantity sufficient; a pinch of salt, with water to make the whole, when well stirred, of a consistency that, when dropped into the cast-iron gem-pan with a spoon, by its own weight it will form smooth. With a little butter, grease the gem-pan hot on top of the stove, and place it in an oven hotter than required for most kinds of bread. Note whether the gem-pan is hot enough to "sizz" when the butter falls into it; for if the oven is not heated hot enough in the start, the gems will be heavy and not fit to eat.

GRAHAM MUSH.

This is made by stirring graham flour in water boiling very hard. Salt to taste, and continue the boiling 15 or 20 minutes. It should not be made very thick. Serve hot with cream, or half cream and half milk, for breakfast, and cold with cream for lunch or supper.

RUSK.

Make dough of graham flour and water. Knead, and roll out on a bread-board; cut into slices, and bake in a moderately hot oven. After they have been baked, continue them in the oven with the door open until all the moisture has been dried out; break in pieces, and grind in a hand-mill. Serve with rich milk or cream.

Madison, Ind., Dec. 1.

A SUBSCRIBER.

Very good, friend S. We hope the readers of GLEANINGS will all give your recipes a good trial, even at the risk of being made "infidels," as your good friend puts it. Now, we do not quite understand the point she makes. Did she sup-

pose that the graham flour was the cause of the infidelity, or was it simply because those who were skeptical in their theology had a preference for graham flour? Never mind; if we can not agree on theology it is comforting to know that we shall pretty nearly agree on the healthfulness of graham bread.

MRS. AXTELL'S EXPERIENCE AT THE KEOKUK CONVENTION.

SHE CONSIDERS THE HALF-DEPT LIGHT HIVES FOR WOMEN.

Friend Root:—I see, from reading GLEANINGS of Nov. 15, that you also was one of the number that enjoyed the International hugely. Yes, that is just the word that would describe Mr. Axtell's and my enjoyment of that convention, and I heard quite a number express themselves as its being one of the best, if not the best they ever attended. Judging from the way people acted, they must have enjoyed themselves, as they would get together at 8, or half-past 8, A. M., and remain up to 12 o'clock, then hurry out to their meals, and back again to commence the meeting at 1:30, and then remain clear up to dark. Gas was lighted, and some one would remark that we were not doing ourselves justice to remain so long, and asked that some one make a motion to be dismissed, when we would hurry out to our rooms and meals, and back again for an evening session that held up to about 10 o'clock; and, what was strange, each meeting was just as interesting as the first, and no one seemed to grow tired. If one grew tired of a position, he felt at liberty to change it or go out of the room; but I noticed they generally came back very soon. Now, why was all this enthusiasm, if it was not that we are engaged in a very interesting pursuit? Mr. Axtell felt that his work was such he did not know how to leave; and, not feeling well, I had to coax hard to get him started. I could see it almost made a boy of him again; and I thought that, if wrestling were a test of boyhood, there were several boys there—old gray-headed boys.

I should have liked to see more ladies there. I wondered why there were not more, when almost always the apiarist's wife or mother or sister takes equal interest with him in the bees. Was it because both could not leave, that one or the other had to stay at home to do chores, look after the family, etc.? I felt almost like accusing the bee-brethren of wanting the good times themselves.

From the little snatches of talk between meetings, as we met in the hall or in the sitting-room, at our meals, or in our rooms, too, we gleaned many useful thoughts. We liked the idea advanced by a Mr. J. D. Adams, of Nira, Iowa, that of being thorough in all we undertake with bees, as well as farming; of making two blades of grass grow where others made but one; of keeping the highest grade of poultry and taking the best of care of it, so that a small flock would pay better than twice the number of mongrels uncared for.

Dr. Jesse Oren, of Mount Auburn, Iowa, puts his bees in the cellar every fall, and goes to Florida, where he has a nice home also, to winter. He says one can buy an acre or two and build a small house, and live very cheaply if he wishes to. He can plant the ground to orange-trees, which come into bearing very quickly. Dr. Oren, before putting bees in the cellar in the fall, burns half a pound or more of sulphur in the cellar, to kill the mold-spores. Since doing

so, his brood-combs never mold. In placing his hives in the cellar, the first hive is placed at an angle of 45 degrees, with the bottom of the back end of the hive resting against the side of the cellar, and the entrance toward the floor. The next hive is placed in the same position, with the back end of the bottom resting against the top of the first, and so on until a row is placed clear across the cellar. The quilts are loosened around the edges, and left on; then he lays a board on top of the first row, and proceeds to place another row on top of the board, in the same position as the first row, and so on until he has all the bees in that cellar he cares to put in—from 225 to 250, I think he said. He makes a compact body of them, and leaves them but a few inches apart in the rows. He leaves them undisturbed until setting-out time in the spring. The hives being raised at the back, the dead bees all fall out, and can not choke up the hive. He said he had wintered thus some 20 years, and is generally very successful. He closes up his house and cellar, as he winters in Florida. Thus he escapes our Northern winters. He is about 20 miles from O. O. Poppleton, in Florida. The doctor is a very methodical man, keeping a close account of all his incomes and expenses, and can tell each year just how much his bees net him. The past year he made his bees pay, as his honey brought him several hundred dollars. I do not remember the exact amount, but it was a fair income. I think he said he had two farms besides. He says he never bothers with small colonies, but tiers them up, putting one on top of the other, thus preventing increase also. He first began the study of the ministry; but as his health failed him he took up the study of medicine and then of bees.

I was pleased with most of the countenances I met at the convention. Intelligence beamed from many eyes—as much so as you would meet at almost any other gathering.

It was a real pleasure to see so many clean-faced young men, and clean lips not stained with tobacco, as so many of the young men of to-day are not ashamed of the tell-tale quid punching out in their cheeks. I was sorry, oh so sorry! to know that to such lips was offered the wine-cup that biteth like a serpent and stingeth like an adder.

PRACTICAL OR ORNAMENTAL.

At the tea-table one asked of another if the lady sitting at the further end of the table was a practical or an ornamental bee-keeper. The question was handled along from one to another until it reached Mrs. J. M. Null, of Miami, Mo., for whom it was intended. Her answer was, "If 6000 lbs. of extracted honey, taken from 114 colonies the past season, by my own hands, except an occasional day's work from a hired man, constitutes me a practical bee-keeper, then I am practical." She also stated that she purchased her own supplies, as her husband was very much afraid of bees, and had his hands full of his own work—proprietor of the Miami House, and owner of two farms. She said she became interested in bees by reading GLEANINGS, and bought and brought some bees home, placing them some distance from the house, as her boarders had great fear of bees, and were horrified to think of her keeping bees; but by and by, being emboldened at seeing her work with them, they would come so near that she had to tell them they might get stung, as they were trespassing upon the grounds of the bees. Her neighbors, also, were becoming more interested in bees.

A BEE-KEEPER WHEN HEDDON WAS A BOY.

A very intelligent old gentleman by the name of B. Taylor, who said he had been handling

bees some 40 years, often having as many as 600 colonies, exhibited a hive of his invention, worked on the principle of the New Heddon hive, only his is 14 $\frac{1}{2}$ inches wide, and 15 inches from front to rear, while Heddon's is 12 $\frac{3}{4}$ wide and 18 $\frac{1}{2}$ inches from front to rear. The hive is in two parts, as is Heddon's. He said he used that principle when Heddon was a boy, and before he kept bees.

One feature of the hive we liked much was the band to set under the hive in wintering, to raise up the frames one inch higher than in the summer, as that is what we practice in our own apiary, and it prevents the hives clogging with dead bees in the winter. I believe I shall like his double super too, as it will be so much lighter for me to lift when full of honey, as I nearly paralyzed my arms in the summer of 1889 by lifting honey and heavy hive-covers. I believe it would be wise, where men expect their women-folks to care mostly for any one apiary, to make all the supplies, hives, covers, and all, as light as possible, for this reason. Several of us lady bee-keepers there at the convention at once said that that was a woman's hive. I was delighted when I found he was going to present one of his hives to me. I felt it was of the Lord, to lighten my work somehow, not by discarding our hive, but by making it and its fixtures lighter. Yet I think I shall like the Taylor hive very much, so I transferred a colony of bees into it as soon as I came home, so as to be sure to have it there for next season's work.

He claimed for his double super, that, when the middle sections were filled, the super could be turned around, thus putting the partly filled ones in the center, and the filled ones on the outside; also, in putting on supers in the spring, rather weak colonies need have but one of them until they get well at work, and then the second could be added.

He is a very practical man, making all his own supplies, except where pine is used, cutting the timber from the tree, drying his own lumber, and manufacturing his own supplies; and, judging from the samples he showed at the association, of sections and hives, Mr. Axtell says his work was first class, as he says it was done as well as the sample shown.

Roseville, Ill., Nov. 26. MRS. L. C. AXTELL.

(To be continued.)

Mrs. A., I most heartily indorse all you say in regard to the convention; and I am exceedingly glad that you have got acquainted with our friend B. Taylor. If you have a colony already in one of his light shallow hives, we may expect you to give this form of hive a good practical test. I believe, with you, that the Lord has called you to investigate this very matter, with the end in view of making the work lighter for our women bee-keepers.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

DISPOSING OF THE WASTE PRODUCTS ABOUT OUR HOMES.

One pleasant thing about the business of market-gardening, either under glass or out in the open air, is that the market-gardener finds a *money value* in the very things that ordinarily are considered the greatest nuisances about our homes. We have already so thoroughly discussed the matter of disposing of sewage, night-soil, etc., that I need not go over the

ground again. My reason for taking up the matter once more is, that some new experience has come to us. Some years ago, when I asked about the best manner of disposing of the products of the out-buildings around our homes, some of the GLEANINGS readers referred me to the Smead system of dry closets, etc. We have, at the expense of a considerable sum of money, just had our entire plant supplied with the Smead closets. As I have watched the workmen, and carefully scanned, scrutinized, and experimented with every feature of their invention, I think I can tell you all about it. In fact, the biggest part of it is using simple principles that we bee-keepers have already for years been thoroughly conversant with. Over and over again, through our bee-journals, has been described a plan of ventilating a beecellar by connecting it with the chimney of the house. A stovepipe goes from the chimney down close to the floor of the beecellar. The draft from the stove *pulls* up all foul gases and bad odors. Well, this is the Smead system. But he puts up a great chimney—in our case, 30 inches square inside. This goes up 12 feet higher than the highest part of the roof of the building. At the bottom of this chimney, or stack, is a furnace. Any place to build a fire will do. The more kitchen stoves, bake-ovens, and every other kind of stoves, you turn into this chimney, the better. Now have your closet right in your house, anywhere you want it—close to the kitchen stove or dining-room, or down in the cellar, or upstairs. Or, if you choose, you can have a closet upstairs and one downstairs, and one in the cellar. The draft from this big chimney of yours will pull every bit of bad air and offensive smell away so completely that your closet will be as sweet-smelling as your sitting-room or pantry. The Smead folks furnish iron seats, with an iron lid to shut down. This lid is hinged so it shuts itself when not in use. The floor is cast-iron. This is painted with asphaltum, so that it can be washed whenever it need be. There are many little holes in this floor. When washing, the water goes right down through these holes, and any bad smell there may be in the room is drawn at once through the holes in the floor. If you make a smoke in the room by burning some paper, the smoke and even blaze will at once shoot down through these holes in the floor; and if the cover of any of the seats is raised, a burning paper held near the opening will show that it draws like the door to your stove. Haven't we been stupid, that we never thought of this before? Now, if you still prefer to have an out-building, as most farmers do, make a brick or wooden chimney to this wooden out-building. Have it go so high that there will be a draft to it. Such an arrangement will make any ordinary out-building ever so much sweeter and pleasanter, even if you do nothing further. When you are going through the country on the cars, just watch the out-buildings as you pass by the homes of our people. You will notice that many of them have a ventilating-shaft already—in fact, almost all *new* ones have. But these ventilating-shafts are too small and insignificant. Let them go up a good deal higher, and make them a good deal larger.

Now for another matter: If you have practiced drawing away the night-soil on wagons and sleds, as we have done for years past, you have found out that it is a very heavy material to handle, besides being very disagreeable. Well, how large a portion of this great load of offensive matter do you suppose is made up of water? Suppose you evaporate the water so you have only the dry residue. Let me give you a statement that will astonish you. The whole amount of accumulation of a large

schoolbuilding, of several hundred pupils, during a *whole term*, was carried away on a *wheelbarrow*. The watery portion had been all evaporated by the hot air of the schoolbuilding, after it had done its duty in warming the rooms. Right under the seats of the closets, about two feet from the ground, is a series of iron bars. These bars are far enough apart to catch the ends of dry bricks laid close together. Of course, there is an air-space all around each brick. Well, the hot air, after it has warmed the schoolrooms, goes under and through this brick floor, keeping the bricks hot and dry. The droppings, both liquid and solid, are evaporated as they accumulate. If, however, in warm damp weather, when the furnaces do not need to be used, the ordinary draft of the shaft is not sufficient to dispose of all the liquid, a slow fire is made to send enough dry air through the brick floor and up the shaft, to keep the thing sweet and clean. By increasing the heat you may *cremate* the entire contents of the vault at any time you wish. A furnace is also put at the base of the shaft, to be lighted whenever the janitor notices, by the action of the smoke from burning paper, that there is not sufficient draft up the large chimney. In other words, whenever there is a particle of smell to be detected by the *keenest nostril*, a great flood of dry pure air is sent through the whole apparatus until every thing is dry, sweet, and clean. Now, then, has any thing ever been invented to compare with such a system of disposing of these waste products as the above? Of course, ordinary homes do not require such an elaborate structure in all its details as the one I have described; this is specially for schools, factories, court-houses, and such places. The only rival system is the water-closet. But what in the world are you going to do with the sewage in the average country town, school, or factory? Champion Brook runs right through our village of Medina; but the man who would turn the sewage from a water-closet into Champion Brook, above the town, ought to be prosecuted, and doubtless would be. We have read in the papers of the great troubles the managers of the Croton Aqueduct (that supplies the city of New York) have had to keep sewage from being turned into it. There has also been a little breeze through the papers in years past, to the effect that it is not safe to send all our bad smells up a big chimney to fall down on our neighbors after a while. It seems to me, however, the absurdity of this objection should be apparent at once. All our foul smells *are* and *always have been* turned out into the open air. Now, is it any worse to turn them loose in the wind at the top of a chimney *forty feet high*, than to turn them loose on a level with the ground? I have not yet been up to the top of our tall chimney to find out what kind of smells are pouring forth; but in any event I would much rather they would pour forth up there than anywhere else. In one of the basements of our establishment we have a kitchen where they cook dinner for the workmen—both men and women; and we have always been annoyed more or less by certain savory and unsavory odors from the kitchen coming up through into our office and other rooms. It has sometimes seemed as if this always happened when distinguished visitors happened to be looking over our premises. Well, since this great big chimney has been doing duty, our cook can have onions, doughnuts, or whatever she chooses, for dinner, and no one's nose informs him of the fact before he sits down to the table.

What has all this long story to do with gardening, do you ask? Why, simply this: The residue that has heretofore been such a terrible load to carry out on our fields, and plow under

(*without a moment being lost*), is now simply a dry fertilizer like guano or dry poultry manure. It may be taken in the hands, or pounded up to be evenly worked into our plant-beds, just as we put in bonedust or phosphate; and the Smead folks say it is worth just as much in the latter form as it was in the former. I wish Prof. Cook and friend Terry would tell us what they think about this last idea.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

QUESTION 174. *What evidence have you had that bees are more likely to supersede a queen that is clipped?*

None.

Wisconsin. S. W.

S. I. FREEBORN.

None whatever.

Illinois. N. C.

J. A. GREEN.

Not any. I don't think they are.

New York. C.

G. M. DOOLITTLE.

Not much when only a part of one wing is clipped.

New York. C.

P. H. ELWOOD.

There is no evidence, and I do not believe that that tendency exists.

Ohio. S. W.

C. F. MUTH.

Not any. I have not the least idea that it is true with me, at least.

Michigan. C.

A. J. COOK.

We used to clip the wings of queens long ago, and have never noticed that they were superseded on that account.

Illinois. N. W.

DADANT & SON.

I don't believe that a queen will be superseded any quicker on account of having her wing clipped. We clip all of ours.

Wisconsin. S. W.

E. FRANCE.

We have not practiced clipping; but bees have always evinced a disposition to supersede a queen crippled in any way.

Illinois. N. W. C.

MRS. L. HARRISON.

The evidence that bees are not satisfied with imperfect, or maimed or crippled queens, as every observing bee-keeper knows.

Ohio. N. W.

H. R. BOARDMAN.

I have practiced clipping my queens for the past eighteen years, and I rarely have one superseded. I think there is no foundation for the belief that clipping causes superseding, providing the apiarist is on hand to take care of the clipped queens when they swarm.

Vermont. N. W.

A. E. MANUM.

I can't say positively; but, not having kept a record, it *seems* to me that there is more likelihood of being superseded when clipped; *but* I have had but little superseding done to clipped ones; for, unless extra good, I keep none over two years, and they are seldom superseded at that age.

Ohio. N. W.

A. B. MASON.

I have no evidence to that effect. I do not practice clipping queens' wings, though I have done so in times past. When I did clip I was sure they lived to a good old age, and died full of honors.

New York. E.

RAMBLER.

I have clipped my own wings from answering this question by not tolerating the practice. But, without much doubt, bees are guided mainly by smell in the matter of superseding queens. A good queen keeps the hive faintly suffused with the smell of fertility; and while this is the case they do not care how many legs and wings she chooses to wear, and would probably ask no questions if she got along without a head.

Ohio. N. W.

E. E. HASTY.

The best in the world. When about half of one of my apiaries has clipped queens and the other half not clipped, their blood and age being the same, I found the most and earliest supersedures where the queens were clipped; and the tendency for swarms to reswarm was something like ten times greater where the queens' wings were clipped.

Michigan. S. W.

JAMES HEDDON.

My two years' experience in clipping all my queens does not afford evidence of their being more readily superseded on account of being cropped. I once had an imported queen that had one wing off, one rear leg off, and foot off the second leg on the same side. I do not know how old she was when I got her, but she continued to lay to the fourth year as well as any queen I had.

California. S.

R. WILKIN.

Nothing, except what I have read. I really don't believe it makes any difference. A good many years ago I saw in one of Mr. Root's colonies a queen with no vestige of a wing, looking like a big ant, and yet I think she had the entire confidence of the whole community. If supersedure comes from partial loss of wings, this total loss ought to have hastened matters. Did it, friend Root?

Illinois. N.

C. C. MILLER.

Perhaps our good friends Boardman and Heddon, after seeing the array of heavy testimony to the effect that clipping makes no difference, may modify their decision, unless, indeed, they are of a class that never take any thing back, no matter how much proof is offered—which I am sure they are not. I have at times thought the bees seemed more disposed to supersede a queen with her wings clipped; but with these good friends of mine against me, I am quite ready to give up. I do not like to see them clipped myself, however; and a good many times something turns up to make me wish that a certain queen had wings. On this account I have recommended that they be not clipped any more in our own apiaries. I well remember the old queen that looked like a big ant, friend Miller, and I think we had her for at least three seasons, and she certainly did as well as any queen in the apiary.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

AIR-SPACE VS. PACKING; DOUBLE-WALLED HIVES.

Permit me to ask the following question: Are double-walled hives with air-spaces unpacked, as effectual in retaining the heat generated by the bees as they would be with those spaces packed? and would they be cooler, in summer,

unpackd, than otherwise? I should like the replies of best authorities on bees through GLEANINGS.

E. W. SMITH.

West Canaan, O., Nov. 27.

That is just what we want to know, friend S. The question was submitted in the Question-Box department, and a majority of the respondents voted in favor of packing as against air-space. The probabilities are, that any kind of packing between the two walls of a hive is better than none. However, for several years in our apiary one of our chaff hives which we supposed had been packed was found to have never had any chaff at all, when we came to renovate it of foul brood by boiling. This one hive occupied a conspicuous place in our apiary; and although it had only a dead-air space, it wintered just as well as the packed hives, so far as we could see, for a period of seven or eight years. How much longer it would have continued to do so I can not tell. In a moderate winter climate like ours, I am of the opinion that the air-space will do just as well; but in colder climates, no doubt packing is an additional protection. The W. T. Falconer Co., of Jamestown, N. Y., have for years sold what they call their Chautauqua hive. This, I believe, has no packing between the side walls. It is practically a hive with a dead-air space. We have had reports of comparative tests between this and our regular chaff hive, in which the bees seemed to winter about as well in one as in the other. Just now I do not recollect the exact latitude from which these reports were made. If any of our readers who are located in cold climates have had opportunities for making such tests, I should be glad to have them report. Henry Alley, in a recent article, said that the air-space did as well as packing in his locality, and we have had many reports to the same effect. This matter is of peculiar importance just now, on account of the discussion going on in regard to an outside protecting shell for winter; for if such a case, without packing, in most localities, will winter successfully, it will be a great saving in the cost of hives in outdoor wintering. Do not understand that I say this *can* be done. I am only awaiting the results of experimental tests by ourselves and others.

E. R.

DOES COMB HONEY EVER TURN YELLOW?

We notice the comb honey we received from you in October is turning yellow, which makes it unsalable. Please advise us what to do.

Massillon, O., Nov. 29.

DIEHLHENN BROS.

I have never heard of such a thing before. Is it not possible that you are mistaken? We have the same honey in stock, and ours has not changed a particle. I have heard of setting yellow comb honey in the sun in a window, and that the sun would bleach it so as to make it whiter. The honey you had was some of Mr. W. K. Ball's, which we have regarded as so very fine. Some of his comb honey had yellow cappings, and some white. To make it fair,

the sections were mixed together, the quality of the honey in either case being the same. It is quite possible that you first removed the sections of white capped honey by accident, and, later, pulled out some with darker cappings. In any event, the white capping should not turn yellow in so short a time out of the hive.

WHAT IS A "HONEY-QUEEN"?

I should like to know what is meant by a honey-queen, as I have noticed advertisements in GLEANINGS where they have stated that they have such for sale. C. A. DICKMANN.

Gehm, Mo., Nov. 24.

What we mean by honey-queens is queens whose progeny rather excel in honey-gathering qualities, their color and that of the bees being secondary, although showing at least three yellow bands. Honey-queens that are sold are raised from some queen whose progeny has excelled the others in the apiary for real work. It is possible that the bees of such queens may not duplicate those of their mother; but as they are bred from that sort of stock the chances are pretty good.

THE COLUMBIAN FAIR.

We take pleasure in copying the following from the pen of Dr. A. B. Mason, as it appeared in the *American Bee Journal* for Nov. 29:

Friend Newman:—I sent a portion of my address, read at Keokuk, to the Director-General of the World's Columbian Fair, and a part of the reply, received yesterday, reads as follows:

In response, I have the honor to say, that at the present time it is not possible to give you definite information as to the plan of organization of such a department, further than to say, that the bee-culture industry will be amply provided for in the classification of exhibits. Your letter will be filed for consideration at an early date when this subject is acted upon. I remain yours very truly,

GEO. R. DAVIS, *Director-General*.

I should like to suggest that the President or Secretary of each State Bee-Keepers' Association let me know, at once, about the amount of space the bee-keepers of their State will be likely to want at the Columbian Fair.

I expect to ask for about 3000 square feet of space for Ohio; and if the other States that should exhibit will do so in proportion, we shall need from 100,000 to 150,000 feet of space, and will "astonish the natives" with the magnitude of the display.

In a "P. S.," Gen. Davis says: "We will soon send you classification and application for space," so it will be seen there is no time to lose.

Let each State society at its next meeting choose a committee to have charge of getting up the State exhibit, and the securing of an appropriation by their next Legislature to defray expenses, for it will take money to make a creditable display.

If any should write me for any information they will do me a favor if they will inclose one or more stamps for a reply; and then be *sure* to sign their name to their letter. Yours truly,

A. B. MASON.

INCENDIARIES IN THE HANDS OF THE LAW.

Mr. Root:—I am glad to inform you that I have succeeded in arresting the boy who set fire to our shops last spring. There were two of them. One is now at the State Industrial School at Waukesha. He made a full confes-

sion; and as soon as the other boy was arrested he also confessed, telling the same story as the boy at Waukesha. They say they simply wanted to see a great fire. One is eleven years of age, and the other thirteen. I am very glad to know how the fire started, and to know it was not done through any emity.

Watertown, Wis., Dec. 4. G. B. LEWIS & CO.

We are very glad indeed, friends, to know that you have got hold of the culprits; yet it seems a sad, sad thing to find that boys only eleven and thirteen years old are abroad in our land who can be guilty of such a terrible crime. Surely these boys have been neglected. My first thought was, "Were they in the Sunday-school and in the day-school?" Do they have laws in Wisconsin compelling people of that age to get an education whether they will or not? We, too, rejoice to know that it was not through any jealousy or envy at your success as business men.

THE DOVETAILED HIVE EASY TO SET UP.

The Dovetailed hives, etc., have been received in good order. I think I shall like them better than the Simplicities, because they are lighter, cheaper, and easier to set up.

BISULPHIDE OF CARBON FOR ANTS.

I notice in Nov. 1 GLEANINGS that Mr. W. F. Elliott, of Clio, Tex., desires a remedy for red ants. Let him try the bisulphide of carbon, so often mentioned by Prof. Cook. Directions: Pour about a pint into the hole; cover for about a minute, then explode the vapor that has formed, by burning a rag tied to a stick, and close up the hole air-tight. They call it ant-poison here. It is excellent for killing night, or cutting ants.

JAPANESE BUCKWHEAT.

In spring I sowed 5 lbs. of Japanese buckwheat on about $\frac{1}{2}$ acre of rich land, from which I harvested 3 bushels. September 12th nearly a peck was sown on the same ground, which yielded almost four bushels. The bees worked on it in great numbers in the morning.

Yorktown, Tex., Nov. 29. R. WESTPHAL.

WARRANTED QUEENS.

1. If a queen-breeder guarantees or warrants untested queens purely mated, and some of his queens sent out should show two and three yellow bands (no black bees at all), would such queens be called mismated? 2. Should such queens be replaced, under above conditions?

High Hill, Mo., Nov. 3.

J. N. S.

Yes, to both questions, most assuredly. Unless a queen produces *all* three-banded bees, she is mismated. See our ABC book.

STRAWBERRY-GROWING IN FLORIDA.

Friend Root:—I would say, in reply to your comments on my letter in the Nov. 1st GLEANINGS, that the berries bear only one season, and are then turned under, and young plants set again. The long bearing season exhausts the old plants so that they are of no value for another crop. I have never had berries for Thanksgiving or Christmas, but for New Years day we have had them. We have Jessie, Burbach, Indiana, and Nunan—the latter the main variety planted in Florida—all growing finely; and to-day we are having a steady rain that

will make it a Thanksgiving day for all vegetation as well as human kind, as we have had none for a month.

H. G. BURNETT.

A va, Fla., Nov. 27.

STRAY STRAWS.

EDITED BY DR. C. C. MILLER.

Mice make mischief many times in the cellar. If they would only eat what honey they want it wouldn't be so bad; but they destroy so much brood comb. Latterly I keep them out of the hives by covering the entrance with wire cloth, three meshes to the inch. It keeps the mice out without shutting in the bees. I like it.

REVERSIBLE BOTTOM-BOARDS.

After a trial of more than a year these prove quite satisfactory to me. They were less troublesome to reverse this fall than last, because the hives were not out of square. I'm sure that a two-inch space under the bottom-bars is a good thing.

CHAPMAN HONEY-PLANT SEED.

This is yielded in good quantity, and is said to contain much oil. I picked some heads and threw to the chickens. They wouldn't touch it. Then I picked out some seed looking like grains of rye. They ate these readily, and some of them then began to eat the seed with the hulls on. Could this seed be profitably raised for chickens?

B. Taylor, Forestville, Minn., has the laugh on me. The little sticks between sections that I paraded as my own "git up" were shown to me by him in Madison last winter. My "forgetter" was in good working order.

Hon. R. L. Taylor is an exasperating customer. In his President's Address he spoke of the "fact" that honey "may be kept in perfect condition from one year to another," but didn't tell how. I wrote, challenging him to tell. Back comes a postal, saying, "I have kept honey over in perfect condition, and it sold without question at the same price as new honey, and it was really decidedly better," and a few words of sauce, but not a word about the "how." If comb honey is meant, I have known of only two or three cases of keeping over in good shape, and that on a very limited scale. Whether he has a different or the same plan, it is important to know about it, and Bro. Taylor is not the sort of man to make a statement without solid foundation. Let's make him tell or put him out.

The papers now have an imitation of comb so natural that the bees themselves are deceived by it, and eat it in winter. Next!

Years ago a bee-keepers' department in an agricultural paper was a rare thing. Now it is common. The busy bee has buzzed itself into notice.

INTRODUCING QUEENS.

Joshua Bull, in the *Ap'l.*, says that for years he has had complete success in introducing queens, provided there was a virgin queen in the colony to be operated on. All that is necessary is to remove the virgin, "and immediately let the laying queen loose upon the comb right among the bees."

Got caught, didn't you? The weather stayed pleasant so long, that, when the cold snap came on the first of December, there were things still undone that you expected to do before the freeze-up. Weather always does that way. Look out next time.

Temperature in the cellar is important. The general agreement seems to be that 45 degrees

is about right; but don't you depend entirely on that. Cellars differ. Thermometers differ. Hives differ. Take 45 for a starting-point, and then find whether your bees are any quieter above or below that.

I believe my bees are better off above 45 rather than below, in the cellar.

Editor Alley is a law unto himself in a good many things. He's generally emphatic in whatever he does. He is very emphatic in the December number in mixing up the editorial "we" with the common, every-day "I," changing from the one to the other with a recklessness very refreshing, ending up with "I regret we." All right, friend Alley. The "we" business is becoming antiquated.

Don't you wish GLEANINGS would come once a week, especially in the winter? Well, the next best thing, if you do not already take them, is to take another of the bee-papers. There are several that I shouldn't like to be without.

Have you ordered all the supplies you need for next year? You'd better. If you wait till about the time you need them, you may be delayed, and now you may get a discount on them.

Last summer when work was crowding, you and I had hardly time to read the bee-journals, and sometimes could take time only to glance through them. Wouldn't it be a good plan to read them all over this winter?

Some editors think they know every thing. They don't. Most of them don't think so. They are always glad to get suggestions from their readers. I am reminded of this by friend Root's request that patrons offer suggestions to make his catalogue more helpful and convenient. So it will be a good plan, if you think of anything that would improve a bee-paper, to write the editor about it. But don't get mad if your suggestion is not followed. In nine cases out of ten there are good reasons why it should not be.

Think of comb honey being "wanted" in San Francisco at 13 to 14 cents a pound. But it seems to me it hardly goes up in proportion at the North.

Will honey drop in price about the first of January? Usually it does. But one year, when it was hardly as scarce as now, it kept going up till late in spring.

I am reported as saying at Keokuk, that the large black ant will not honey-comb bottom-boards if they are kept off the ground. I don't know whether I said just that, but I know I didn't mean it. I am not sure that they will trouble if the bottom-board stands directly on the ground. The worst trouble seems to be where the bottom-board stands flat on another board. The ants seem to commence work between the boards. I think they will not trouble if nothing touches the under side of the bottom-board only around the edges.

The Honey Column in GLEANINGS is good, all but where some one says, "Prices remain unchanged." It isn't pleasant to be obliged to look back one or more numbers to see what the price is.

I wish I could get my bees trained like Manum's to put off the brace-comb business till fall. Mine seem to be just as bad early.

Oh, but ex-president Taylor will feel conceited when he sees his picture in the report of the Keokuk convention!

"Volunteer Contributions" appears in two programmes that I have seen. That may be all very well for a little while; but some of these days somebody will wish that "Volunteer Contributions" had never been born.

Jones protests against the last part of foul-brood treatment given in Mr. Pringle's Keokuk essay. He says it isn't safe.

MYSELF AND MY NEIGHBORS.

Not by might nor by power, but by my Spirit, saith the Lord of hosts.—ZECH. 6:4.

Dear friends, this is my closing talk for the year 1890. The question has been on my mind for some days, "What shall be the last thought of the year? What subject is of most moment and most importance just now, to the readers of GLEANINGS?" A very kind letter from a friend who furnishes me some valuable facts in regard to artesian wells, furnishes me my subject in these closing remarks. It is as follows:

Friend Root:—I was surprised at your reasons for giving money to a railroad company. What does the Scripture mean when it says, "He that giveth to the rich shall surely come to want"? If the railroads of this country are not rich, then I don't know as much as I thought I did. One can walk cheaper than to ride on a railroad. To make a long story short, they are robbers. I have often wondered what kind of people the Nazarene was speaking to when he said, "My Father's house shall be called a house of prayer; but you have made it a den of thieves." I trouble you with this, because you are one of a few that desire to do what you can. We here in South Dakota can see that capital and labor will clash unless the difficulty is settled by ballots. There is a party here, six months old, called Independents, who will always be "independents," in my opinion.

De Smet, S. D., Nov. 18.

S. L. R.

Had the above come from only *one* correspondent, I should not have thought much about it; but I see the same spirit in other letters, and here, too, among my *neighbors* in Medina. I find it in the papers that are scattered so freely throughout our land. Perhaps the railroads are not very often so strongly condemned as in the above, but yet there is more or less of that sort of feeling prevailing. Our friend is evidently looking toward legislation and the ballot to right his wrongs. Well, there may be something for American people to do in that line; but it is so much out of my department that I will not even try to touch upon it to-day. The great thought that comes to me, and lies heavily upon my heart, is, that Satan is constantly entrapping us by persuading us that our neighbors are *all* evil; and especially has this thought got into the heart of the *laboring classes* toward those who wield the *capital* of our land. Dear friends, I am sure that capital and labor should go hand in hand, just as a husband and wife should go hand in hand. I am sure that God has intended that capital and labor should be *wedded* together. Their relations should be kind and loving ones. Each should seek to assist and aid the other—or, as is said in one text, "In honor preferring one another." The husband should make it his constant study to assist and help and please his wife; and she in turn should make it her constant thought to minister to his comfort, each one setting aside self for the good of the other. Now, when capital and labor can be doing just this, then shall we have a millenium here on earth. But doubtless many of our readers will say, "Capital has not done this, and does not propose to do it. Capital is the *stronger* party, and labor the weaker one. Labor always has submitted—at least almost always—and you would recommend, Bro. Root, that labor *still* submit." No, I do not. I know capital has a seeming advantage; and I know, too, that capital has been, in some cases, very lofty, overbearing, and unfeeling. In the very same way, many husbands, by their superior strength, and perhaps greater knowledge of the world, and possibly greater mental force, have the advantage, and in a brutish, selfish way, propose to keep it. Both pictures are sad ones. Where is the remedy? I should say, dear friends, before

we try legislation or the ballot—that is, before we rely entirely upon these agencies—we should look into our own hearts and see that *they* be right; be sure they are in fighting trim. You know what I mean by "fighting trim." The fighting to be done is in the line of the text I have chosen at the head of this talk—"Not by might nor by power, but by my Spirit, saith the Lord of hosts."

Let us take our friend's letter in order. First, he expresses surprise that I should give *money* to the *railroads*. Why, dear friend R., it is these same railroads that are revolutionizing the earth. Without the railroads *you* could not *live* where you are now. Without them we should be in barbarism, as other nations are now, and where they must stay until railroads can let the light of civilization shine in upon them. It is the railroads that enable us to live in places where famine and starvation would be constantly recurring without them. See the examples in the Old World. For want of railroads the inhabitants of China, in certain districts, are starving to death by the *million*. A former pastor of our church is now in China. He told us of a railroad that was built in China some years ago. The Chinese let the same bitter spirit enter their hearts that now and then comes into the hearts of our people here at home, and they tore the railroad all up—demolished the locomotive, tore up the track, bent the rails, and then—well, what then? Why, they *starved to death* during poor seasons, just as they have been doing for centuries past! Dear brother, you do not give the whole of that beautiful text from Proverbs, about giving to the rich. The whole verse reads, "He that oppresseth the poor to increase his riches, and he that giveth to the rich, shall surely come to want."

You will notice the starting thought—in fact, the leading thought in the verse is, "He that oppresseth the poor to increase his riches." Then follows the other part of the figure in regard to him that should favor the rich. That is, if a man wanted some work done, and instead of letting a *poor* man do it he should give the job to a *rich* man, such a one shall surely come to want. Is not my construction right? You think that I gave to the *rich* in giving to the railroad. Why, dear brother, it is my own friends and neighbors who are building that railroad. The prime mover in the whole project is a little energetic, wiry man who lives in a neighboring town. He has been working for an east and west railroad for all of five or six years. He got it started and under headway some years ago; but one disaster after another snowed him under, and we supposed he was hopelessly ruined. He kept at the work, however, winter and summer. Just before we got the road under way I laughingly told him that, if *anybody* deserved a railroad, he did, in answer to his indefatigable industry and perseverance. He told me confidentially that, if it failed *again*, he would be hopelessly ruined, and we, *too*, would have our chance of getting an east and west railroad, as an outlet for our increasing business, for ever lost. At one of our railroad meetings it seemed as if the project must be given up. The people began to lose heart, and go home. Then I stepped in and gave them an exhortation, and made some rash promises, as some of my friends thought—something like matching every subscription that would be made during the remainder of the evening. They rallied, and came back; and we got so near the desired goal that night that the railroad took a fresh start and went ahead. Railroads and printing-presses, dear brother, follow in the wake of missionaries, as you well know. It is true, many vicious and profane

men are engaged in building and managing railroads; but for all that, they carry the gospel of Christ Jesus everywhere they go.

You declare that the railroads are rich. Are the railroads of our country *all* rich? Why, dear brother, they must have *capital*, or they could not exist. But look about you, and see how many of them fail to pay expenses, and go into the hands of a receiver. Such a thing has happened twice to the only railroad that has been in our town for the last nineteen years, and yet you call them "robbers," and others say these companies have *no souls*. To whom do these expressions refer? They must surely refer to somebody. Is it the engineer, the conductor, those who handle the freight, or is it the president of the road and the stockholders? I am somewhat acquainted with these individuals on our road. Some of them are professing Christians, and good men; others are not, just as in all other avenues of life. We are seeking, however, to bring them to Christ Jesus. Shall we do it by calling them robbers? In another column, Dr. Miller has alluded to the stubbornness of the railroad officials in regard to giving us reduced rates to the convention. I have in my possession two very kind, gentlemanly letters from railroad officials explaining why they could not give us reduced rates. They have learned by past experience that the attendance is *too small*. We all know that the attendance at our national conventions is not what it should be. In asking them to give us reduced rates it is something like having a neighbor want you to come in from the field to weigh him up *half a pound of honey*. If you have ever had to do that very much, you have learned that you can not stand it, especially when time is valuable. If you call a neighbor a robber, and tell him he has no soul, you are taking the very *shortest cut* to make him a robber and a soulless knave. By such treatment you may make him so ugly that he loses his ordinary good sense and sense of justice. What does our text say?

Do you really think that Jesus had in mind our railroad men when he spoke about making the house of prayer a den of thieves? It was on only one occasion that he used such words as these. The traffickers had invaded the house of God, and used it as a place to drive their sharp bargains. On such an occasion our Savior took upon himself the responsibility of reproving them and turning them out. When our railroad men go into God's house, they are surely as well behaved as other people; and when it comes to the contribution-box, they usually give liberally of their possessions. Many a church is indebted to some railroad man for its foundation, and may be something more. In California the railroad companies are so firmly convinced that the house of God is a symbol of prosperity that they build beautiful churches outright; nay, more. Whencit comes Sabbath-day they are on hand with their families, and they set a good example to many of the inhabitants of a *farming* community. It is true, when asked if they were members of the church, many of them would say, "Oh! my wife belongs. She sings, and reads the Bible while I listen to the sermon and help pay the running expenses." My friend, the latter is not *all* we could desire, but it is enough for us to be thankful for. Let us pray and work in the spirit of our text, and we have God's promise that the rest shall come.

Friend Terry is at present staying at our home. We are having a two-days' farmers' institute. Yesterday he told us in his talk of a place in the western part of Ohio where butter is selling at 10 cts. a pound. He examined some that a farmer brought into the store, and

he said it was every bit as good butter as he pays 25 cts. a pound for in Hudson, O. In fact, he gave \$25.00 for 100 lbs. of such butter. He ate the butter at the hotel tables, and the landlord assured him that he paid only 10 cts. a pound for it. Now, what does this mean? Bee-keepers have complained of such a state of affairs in regard to honey; but so staple an article as *butter*, and butter of fine quality—why, I was astonished. How does it come? This way: There are no railroads there to equalize prices. Perhaps the people have not enterprise enough to demand one, and to go to work and build it as we did. Another thing, the producers are small farmers, with a few cows apiece. The amount of butter they make is so trifling that they do not inquire into it. They do not read the quotations in the city papers. Very likely these men who sell their butter for 10 cts. a pound sit around the stove in a country store, and call capitalists soulless robbers. What shall they do? Why, bless your hearts, dear brothers and sisters, they should make a little "trust company" of their own, if you will excuse the expression. Yes, call it a "ring"—they need a ring to defend themselves, and they need to work in a brotherly band. If a ring means a brotherly band, then I am in for rings. This little brotherly band of farmers should pack their butter all together, each man putting his name on his package, and send it to some commission house in the nearest large city. Think of the difference—10 cts. and 25 cts., for a staple article like butter! Now, nothing but railroads can cure this state of affairs—railroads and the right sort of spirit between the small farmer and the railroad officials. You and your neighbor need not be at swords' points because you are a day laborer living in a little rented house while he lives in a fine mansion. Your relations may be of the most friendly nature imaginable. He may help you, and you may help him.

If any one will take an unbiased glimpse of the great industries in progress at the present day, I think he must admit that the only possible way to accomplish many things is by combined capital, and by forming great companies. You may call them "trusts" and "rings" and "monopolies," if you choose; but they are really a necessity of the present age. In our talk at the institute I have mentioned, the Hon. Thomas B. Palmer gave us a history of the attempts that have been made, not only in Ohio, but in other States, to improve our country roads. That we might do this intelligently, many good public-spirited citizens labored hard to change the existing state of affairs, and even laws were passed in some sections to have the road-tax paid in *money* instead of *day's work*. This money was to be used by competent engineers and mechanics in making *permanent* roadways. Many of you know that the labor and money expended in working on the road, especially in clay soils, does no *permanent* good. In front of our residence and factory, the travel last winter crowded the clay all out of the roads, and almost up on to the sidewalks, until the center of the road became a filthy, reeking pool of mud. After long delay in the spring until it dried off, our road-makers scraped the clay up in the center again, and rounded it up nicely, and during the summer we had a very fair clay road; but during the two rainy months of October and November, the travel pushed the clay out into the ditches again, and the road is now about as bad as before. All the labor of packing it up amounted to nothing except a temporary gain, lasting a few months. Now, this kind of work has been going on for *thirty or forty years* in many districts. Enough labor and capital have been expended to have

made a macadamized or stone road that would last for years. This matter was presented again and again to the farmers, but they united almost in a body and rejected it. They wanted to stick to the old way of each one working his road-tax, and they carried the day. *Public opinion* was so against the law and the law-makers, that it amounted to nothing, and the law was a dead letter. Are the farmers helpless? are they the *slaves* of capitalists and politicians? They certainly were not this time. In our town we have a beautiful stone road from the depot to the court-house; but we had to fight hard to get it, and it was *not* done by each man putting in a day's work. It was done by the town council. Said our honorable friend in his speech, "My good friends, how long it would have taken to build your stone road from the depot to the court-house had you depended on each man working out his share of it? Why, the *first* stone would have worn 'clean out' before the *last* one was laid!"

Now, this is true; and combination and capital is the only way to accomplish even a little enterprise like the one I have mentioned. The irrigation in California, that has transformed a desert into the most productive land that the world has ever known, is the result of combination and capital. So it is with the railroads, with our factories, electric lighting, our great steamboats, and almost every thing else. There is no other way. Are all these men who are engaged in these things, who wield the capital or who hold the offices with high salaries, *bad* men? By no means. The more I become acquainted with them, the more I feel ashamed of myself for having misjudged them in former years. I can well remember when I used to feel bitter toward our banks and our moneyed men because they would not lend me money without proper security. Why, they did me a *positive kindness* in making me submit to ordinary business rules and regulations. *Bankruptcy* and the *penitentiary* are oftentimes the result of letting somebody have money by mistaken kindness, when he ought *not* to have it.

We are tempted to criticize and find fault because we do not *understand* things. Some one of our neighbors is lucky enough to get a position where he gets a salary of two or three thousand dollars a year. The temptation is great for the less fortunate ones to say that he got it by wire-pulling or by fraud. Such may be the case sometimes, but I do not believe it happens very often. The chances are greatly that he has worked hard (or *studied* hard, if you choose) until he was fitted for the position and deserved it. I have been watching this thing carefully for years. At the present time, while hundreds are applying for something to do, we are sadly in need of a man or woman worth one or two thousand dollars a year. Now, none of you need apply because I say this. There are no such people on the market. *Others besides ourselves* are needing them. There are *good* people, mind you, *plenty of them*—people well educated, and with experience; people who are honest and true, and who will do their very level best, but not people who have worked hard, who are broad and deep enough to see what our nation wants, and who have the *ability* to direct a lot of men and women, or a large business. Such people do not grow themselves. They must be *made* to order, as it were; or, perhaps, better still, make *themselves* to order; and when they are made, *everybody* wants them. Some very good friends of mine have tried to fill these positions. They have been very confident and sanguine, and they have been true and Christianlike enough to admit, when they found the work was greater than they could manage, to say so, and step

down and out. Now, when one *has* the ability to fill these places, for Heaven's sake let us beware how we let envy and jealousy get into our hearts. Let us beware about speaking unkindly or spitefully of him.

Now, friend R., please believe me when I tell you that the men who manage our railroads successfully are the kind I have been describing. When they are opposed by laboring people who will not take the time to inform themselves in regard to these matters, they get in the habit of being short and perhaps overbearing in their answers, for they are by no means perfect in *all* the Christian graces. I do know this: That, when the managers of a railroad find out that a man is disposed to be fair and honest, and does not try to gouge and cheat them whenever an opportunity happens, they are very fair and liberal with him. It gives me pain when I hear the expression to the effect that railway corporations have no souls. It is true, it is not exactly like dealing with any *one* man. But this corporation is made up of a number of men—made up of our neighbors, and the fact that they feel hard and indignant, and many times bitter and ugly, when these things are flung at them, shows they recognize the insult is intended for them, and they often resent it, as you, my friend, would resent an insult. I do not mean to say there are no wrongs that should be righted; and this organization that our good friend calls the Independents may be the right and proper way, providing it works in the line of our text—"Not by might nor by power," but by the spirit of Christ Jesus, remembering that we are constantly dealing with our *neighbors*, and that kindness and brotherly love—perhaps I might say *neighborly* love—will accomplish what bitterness and spite can never do. Our farmers and laboring classes are by no means helpless. I have given you an illustration where they conquered, and had their own way, even where they were in the *wrong*, and the law-makers in the right. If our rural neighbors can carry the day when they are in *error*, who shall say what they may do when their cause is *right* and *just*? Perhaps some of you say, "Why, Bro. Root, how do you *know* we are in the wrong? If we want to make our roads as we have been doing for fifty years past, by scraping the clay up in the center, and letting it flat out again in the winter time, is it not our privilege?"

Well, this may be open to discussion; but I do not think it *is* your privilege. You are in duty bound before God and your fellow-men to consider the good of the people at large, and the good of the people who are coming after you. You have no business to waste valuable strength year after year in something that does no permanent good. You have no business to wear out your horses, and keep your wife and children at home when they might spin over good roads to come to town and attend farmers' institutes, to go to church and Sunday-school, etc., just because you are too lazy, or too little and stingy and mean, to employ competent men to make some *good substantial roads*, just as you would employ competent men to make good substantial houses and barns. I hope this latter clause is in the spirit of the text at the head of my talk to-day. If it is not, may God give me grace and wisdom to see my *own* want of charity.

You know how badly *we* have felt because the great outside world would have it that our honey was all manufactured, comb as well as extracted, and how reluctant our friends and neighbors were to let go of the silly falsehood. Well, now, I am sure that we on *our* side are doing something of the same kind when we accuse those who handle the large commodities of

life, of forming trusts and rings, and the like. Remember what a great stir was made about the trust on binding twine. Well, I took the pains to read up on the subject, and I became perfectly satisfied there was no trust at all, and *never had been!* The sudden demand for twine for binding grain brought about the very state of affairs that comes now and then in every product. Why not accuse the farmers of having made a trust on potatoes that makes them worth *55 cts. a peck* to-day in Medina? Friend Terry has been at our house for two days, and I discussed the whole matter with him most thoroughly. He agrees with me exactly, and, furthermore, says that he believes that even the *Standard Oil Company* has been a blessing to the world at large. He says he believes we get better oil, and at a lower price, than we ever should have had it without them. Now, we may not all exactly agree with him; but yet his charitable feeling toward all these great industries keeps him constantly in a happy frame of mind. The first day of our institute he talked three times, and then again in the evening; and he is going over the whole State of Ohio this winter, doing almost the same kind of work every day. What he contributes to the agricultural papers is written between times. I fear his health will never stand such severe mental labor as he is doing; yet he is doing it out of love to our people, and because he hates to see our Ohio farmers waste *strength, energy, and intellect* in fighting the many things that are like bogus comb honey—things that *never had an existence* at all. I hardly need tell you that friend Terry stands alone by himself, so far as any *ring or combination* is concerned. He is in daily, constant intercourse, not only with the *farming* people, but with our great leading *capitalists*. He has ample opportunity, and no doubt many *invitations*, to use his great and increasing influence to favor different selfish projects; but may the Lord be praised for the fact that money can not buy him—no, money can not swerve him a *hair's breadth*. Can I say as much for you, and *you*, and *you*, my friend? If so, then I can say again, "May the Lord be praised." You are just what our country stands greatly in need of.

And now, dear friends, permit me to close my exhortation to you for this time with a little bit of that beautiful chapter in I. Corinthians, the 13th. If you should see how fully it applies to the case in question, and feel a desire to read more of it, and should take down the family Bible and read the *whole* chapter to the good wife and children, I shall be happier still; and may Christ Jesus bless all these talks for the year past; may the influences of the Holy Spirit so bring them home to your hearts, that you can enter the year 1891 with a broader charity toward all the world, and especially toward our great corporations of which we have been speaking, than you have had before. May you not only have a broader charity, but may you have a happy and willing spirit, thanking God for the chances he has given you to make your way among the crowd; and may you have grace to get a glimpse of the kind and loving spirit that surely *does* exist *somewhere* in the heart of every neighbor round about you, whether he be rich or whether he be poor. Here is my extract:

Charity suffereth long, and is kind; charity envieth not; charity vaunteth not itself, is not puffed up, doth not behave itself unseemly, seeketh not her own, is not easily provoked, thinketh no evil; rejoiceth not in iniquity, but rejoiceth in the truth; beareth all things, believeth all things, hopeth all things, endureth all things.

EDITORIAL.

A soft answer turneth away wrath; but grievous words stir up anger. Prov. 15:1.

SUGAR FROM BEETS VS. SUGAR FROM CANE.

PROF. COOK says there is no difference whatever. See his article on the subject, in our next issue.

THE SMEAD DRY-CLOSET SYSTEM, AND THE VALUE OF THE RESIDUE.

SINCE the close of the article on page 898, I have conversed with friend Terry and also with one of the Smead people. Mr. Terry says he would consider the dry residue of just as much value as to carry it on the ground with so large a quantity of water. The Smead folks tell me the customary way of disposing of the product is to pour on a little coal oil and set it on fire. It will all burn to ashes, without any residue, and it may be burned up once in three months, once in a year, or once in two years, as the owner chooses. The vault of the closet is built of brick and iron bars, so that there is nothing to be endangered while the burning is going on. The smoke and gases go so promptly up the shaft that nobody will know that the contents are burning.

LIFE-MEMBERSHIP IN THE N. A. B. K. A.

New life-members are being continually added to the roll, and so far we feel very much encouraged; and if this membership is to continue at the present rate, we shall keep on harping until the list is swelled to a respectable size. Up to the date of the meeting at Keokuk, these two were the only life-members: D. A. Jones, Beeton, Ont.; Thomas G. Newman, Chicago, Ill. The following is the list of names that have been handed in since, in the order of their receipt: A. I. Root, Medina, O.; E. R. Root, Medina, O.; J. T. Calvert, Medina, O.; Charles Dadant, Hamilton, Ill.; C. P. Dadant, Hamilton, Ill.; Eugene Secor, Forest City, Iowa; Dr. C. C. Miller, Marengo, Ill.; O. R. Coe, Windham, N. Y. We trust that every bee-keeper who is interested in the highest welfare of his pursuit will at once send his name to the secretary, Mr. C. P. Dadant, Hamilton, Ill. If you are unable to pay the amount now he will charge the same to you, and you will then be enrolled in the list as above. The above makes ten names, and all that has been paid in is invested and drawing 6 per cent interest.

REPORT OF THE N. A. B. K. A.

THE 21st Annual Report of the North American Bee-keepers' Association has just come to hand from the publishers, Messrs. T. G. Newman & Son, Chicago, Ill. As usual it is well and neatly printed, and substantially bound in a tinted-paper cover. One thing we notice in particular in regard to this report is, that it is nearly twice as large as any other report of one

convention. The Keokuk report occupies 50 pages, the size of this; the one at Columbus, 26 pages; the one at Brantford, a year ago, 28 pages. Every member will have a copy of the last report, and a good many who are not members should have it. Price 25 cents each, or to members free. Apply to Thos. G. Newman & Son, as above.

BEE-KEEPERS' ADVERTISER.

THE above is the caption of a circular and pamphlet of instruction issued by Henry Alley. In regard to the bee-keepers of York State and the closed-end frames which they use so rapidly and easily, as mentioned by the writer in his recent visit, Henry Alley says: "There, friends, I told you these same things a good many years ago, and not only pointed out to you the advantages of the closed-end-frame hive, but offered for sale one of the best hives now in use. Now that this subject is opened up anew, I have no doubt that thousands of bee-keepers will adopt closed-end frames." The circular can be obtained free of Mr. H. Alley, Wenham, Mass.

COMMON SALT AS A REMEDY FOR FOUL BROOD.

ONE of the bee-friends takes us to task for dismissing the above rather too briefly—see page 822. Our reasons for so doing were these: During the whole time that foul brood prevailed in our apiary, we used salt in front of the hives for keeping down weeds. Whenever there was a rain or even a heavy dew, the bees could be seen in the sawdust around the entrances, helping themselves to salt water to their hearts' content. Secondly, Prof. Cook or some one else has reported testing the matter, with scientific exactness, and the salt water had no effect whatever on the foul brood. We are quite willing, however, to reconsider the matter when any thing positive can be brought forward.

KIND WORDS FROM OUR CUSTOMERS.

THE PAPER-WEIGHT.

I can hold it in my right hand and scratch enough geometry in my head with my left to last two weeks. It is very pretty. WALTER S. POWDER.

Indianapolis, Ind., Oct. 2.

THE NEW DOVETAILED HIVE.

In the new Dovetailed hive, with Hoffman frames, described in Nov. 1 GLEANINGS, you have given the fraternity, I think, a perfect hive, and one which is destined to become immensely popular.

Lexington, Ky., Oct. 31.

JAS. ERWIN.

The honey I ordered came to Newburgh yesterday morning. I find it just as you described, almost as white as water, and of very thick flavor. I am well pleased. Freight was 50 cts. I presume it would have been no more on twice the amount.

Cleveland, O., Oct. 29.

E. HANCHETT.

OUR 15-DOLLAR SEWING-MACHINE AS GOOD AS ONE COSTING THIRTY.

I received your sewing-machine in good order, and I am well pleased with it. I could not have got it any less than \$30.00 around this part of the country, and it sews just as well as the \$30.00 ones. It sews any kind of cloth.

Coultersville, Ill., Nov. 10.

MRS. JEAN BONNAT.

HONEY ALL SOLD—AN ADVERTISEMENT THAT PAID.

Please stop my advertisement in the Honey Column. My honey is all sold. Printer's ink paid me this time.

C. H. STORDOCK.

Durand, Ill., Oct. 16.

THE KIND OF ADVERTISING THAT PAYS.

We don't mind to pay for the ad't, but it brings too many orders and too much correspondence. We hope this will reach you so the ad't will not appear again this season. We have sold some 800 queens this year, and would like to stop, as we want to keep a few for next year. We had to fill an order for 10 to-day. We know it pays to advertise in GLEANINGS and in the *American Bee Journal*.

High Hill, Mo., Oct. 20.

JNO. NEBEL & SON.

KIND WORDS FOR OUR STRAWBERRY-BOOK.

I received the book on strawberries, by T. B. Terry, and I tell you I was agreeably surprised. I have learned more from his book than I ever heard of, and it is so easy that any boy can make a success from it. I want Mr. Terry's A B C of Potato Culture, and Care of Horses and Cattle. JNO. W. HENRIE.

Excelsior Springs, Mo., Oct. 15.

Strawberry Culture.—A forty-cent book on this subject, intended especially for beginners in the art, has been prepared by two good authorities, T. B. Terry and A. I. Root, and is published by the latter, at Medina, O. A number of good illustrations enhance greatly its value.

[We regard the above as a pretty good commendation, especially as it comes from the *Country Gentleman*, a paper so careful in what it recommends.]

The thousands of farmers who ought to grow strawberries for their own table may learn how easily it can be done by reading "The A B C of Strawberry Culture," a little book written by T. B. Terry, and published by A. I. Root, Medina, O. Mr. Root, who is a successful berry-grower, adds an interesting chapter. Both writers give their own experience, and state particulars that are usually omitted in books of the kind.—*Farm Journal*.

This is an admirable treatise on strawberry-growing, written in the usual practical and interesting style of Mr. Terry. It is a book evoked out of his own experience, and for that reason it is doubly valuable. We find much instruction from its perusal; the observations and experience of such men as the author are always apt to lead to improvement, and many hints and suggestions may be found in this little book that will prove of much profit to the strawberry-grower. Mr. Root adds a chapter on Strawberry Culture, and there are some good illustrations from photographs throughout the book. We heartily recommend it.—*Orchard and Garden*.

I have the pleasure of acknowledging the receipt of Terry's and your strawberry-book, for which I am thankful. For fifty years I have been getting about all the works published on this subject; and I can say that I consider yours the best. It leaves nothing untold in the way of how to treat plants and the berries, besides being a very interesting and readable little book. To-day I start to attend the State Horticultural meeting, and in the discussion on the strawberry I shall recommend your work. The new suggestions and plans in your book are valuable, some of which I have practiced; but I was not aware of others' doing it.

S. MILLER.

Bluffton, Mo., Dec. 1.

FROM W. J. GREEN, OF THE OHIO EXPERIMENT STATION.

I have been much pleased in looking over Mr. Terry's strawberry-book, not only with what is said, but with the manner of presentation as well. It is both instructive and entertaining, and all the more valuable because of the better element. It is so full of enthusiasm that it ought to enthrall others. There is need of a book of this kind, for most farmers either believe that they can not grow berries or it would not pay them to do so if they could. This book helps those who would help themselves, and convinces those who are open to conviction.

Columbus, O., Nov. 18.

INDEX TO ILLUSTRATIONS.

Agricultural Ant	457	Durn the Bee-hives	592	Onions and Potatoes	608
Alley's Hive	889, 890	Exhibit of Honey, L. E. Mercer's	16	Out of Work, Illustrated	261
Alley's Automatic Swarmer	417, 418	Exhibit of Honey, Nysewander's	738	Outside Winter Case, Roe's	811
Alfalfa	337	Fastening Hives for Hauling	249, 252	Outside Winter Case, Stephens'	742
Alfalfa Foliage and Bloom	338	Fixed Distances, Jeffrey's	172	Out-aparies, France's System	883
Ames' Double Top-bar	204	Fixed Distances, Phelps'	98	Paper Pall for Extracted Honey	99
Andrews & Lockhart's Apiary	47	Fixed Distances, Van Houten's	175	Peddling Honey with an Ox-team	283
Aphis, Blue and Green	526	Fixed Distances, Norton's	199	Perforated-zinc Ma-hine, Clifford's	894
Apiary, Out, Elwood's	878	Fixed Distances, Foster's	198	Phelps' Staple Spacers	98
Apiary, Smith's	243	Fixed Distances, Foster's	198	Potato-sorter	384
Apiary, Holmes'	245	Fixed Frames, Phelps'	332	Rambler Raising Honey Spoon	95
Apiary, Wolcott's	245	Fixed Frames, Andrews'	416	Rambler Raising Comb Honey	94
Apiary, W. S. Hart's	624	Fixed Frame, Hoffman's	330	Rambler on a Rambler	47
Apiary, Dovetailed Hive	661	Florida Apiary	624	Rambler's Mashup	246
Apiary, Hadsell's	631	Foundation, and why it Stretches	557	Rambler in York State Hills	743
Apiary, S. E. Miller's Proposed	524	France's Out-aparies	883	Rambler Guessing Riddles	800
Artesian Well, Woonsocket	699	France's Shot-tower Hive	873	Rambler's Pickers	346
